CLINICAL NOTES

ON THE

ELECTRIC CAUTERY IN UTERINE SURGERY.

BY J. BYRNE, M.D.,

SURGEON-IN-CHIEF TO ST. MARY'S HOSPITAL FOR DISEASES OF WOMEN; CLINICAL PROFESSOR OF UTERINE SURGERY TO LONG ISLAND MEDICAL COLLEGE, ETC.

CASE XVI.

LARGE FIBRO-CELLULAR POLYPUS OF THE CERVIX; FIRST NOTICED FIVE DAYS AFTER PARTURITION.

Mrs. M——, aged 28, was delivered of her third child April 6th, 1870. During gestation nothing occurred to excite her suspicions, and her general condition was in no way different from that observed in two previous pregnancies. In this third labor, which lasted but a few hours, she was attended by a midwife, and no difficulty occurred further than that the after-birth was slow to come away. Yet she was sure no undue traction had been made on the cord.

Three or four hours after delivery she was seized with very severe expulsive after-pains, which lasted for three days, then subsided, and her condition for the following two days was, on the whole, comfortable.

On the fifth day, being without a nurse, and having no one to care for her children, she ventured to get up and walk about; but no sooner had she done so than a large substance, which she thought was her womb, protruded from the vagina. She immediately returned to bed, and so remained until I was requested to see her, which was on the 14th (eight days after confinement). During these three days there was a constant passive hemorrhage, and she appeared very weak and anæmic; but she complained of no pain, and the greater part of the tumor had retreated within the pelvic cavity soon after assuming the recumbent position. In shape it was ovoid, or rather pyriform, about the size of a uterus at from three to four months' gestation, and of firm consistence, except at its lower surface, where it yielded readily to pressure from below upward, but immediately recovered its convexity on the pressure being removed, thus giving a very distinct impression of its being hollow. Several abraded spots were observed on its sides and inferior surface, from which blood oozed, and the whole was of a deep flesh color.

In accordance with my advice, she was brought to St. Mary's Hospital April 16th, 1870, when a careful examination was made with the hope of deciding as to whether this was really a case of inversion of the uterus or a polypus. On introducing two fingers within the vagina and making traction on the prolapsed mass with the other hand, it was found that there was no cervical rim, but, on the contrary, the vaginal surfaces and that of the tumor were continuous, except at one small spot

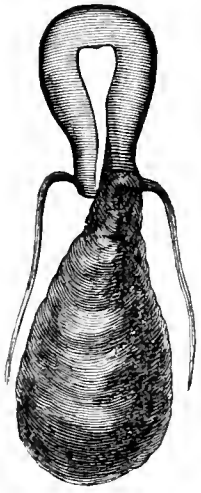

Fig. 15.

anteriorly, which was depressed. Here an effort was made to introduce a probe or sound, but unavailing. By examination per rectum and pressure above the pubes, I failed to satisfy myself of the presence of a uterus above, and for the time being desisted from further efforts at diagnosis. At this juncture, the case being one of unusual interest, I requested Drs. Thomas, Noeggerath, and James L. Brown to see her with me. The same steps towards forming a diagnosis were again resorted to, and after repeated efforts Dr. Thomas managed to get a probe into the cavity of the uterus from the bottom of the little concavity in front, and thus all doubts as to the position of that organ and the character of the tumor were at an end. It is but proper to state, however, that before the cavity of the uterus was reached all present felt certain of having detected, by bi-manual examination, a body which it did not seem possible could be any other than the uterus. Nevertheless, had every attempt to reach the cavity of the uterus failed, and no other evidence of its existence above been found than that afforded by the rectal and supra-pubic touch, the true nature of the case must still have remained doubtful; because, supposing this to have been a case of inversion, it is very easy to imagine how a subperitoneal fibroid might have swung into the position vacated by the inverted uterus, and thus deceive the very best diagnostician.

Again, though, as Dr. Thomas observes,* the presence of a body in the uterine region may warrant

NOTE.—Owing to a mistake on the part of the printer, a foot-note at page 557, which reads: "Two operations were resorted to in this case within the last month," &c., has been misplaced, and refers to case No. XI. on the next page.

Also, by a typographical error, the whole number of cases treated is put down in one place as 73 and again 70, whereas in each instance it ought to read 72.—J. B

* Diseases of Women, 3d edition, p. 412.

a more or less forcible introduction of a probe when, owing to the agglutination of tissues by inflammatory action, the aperture may have become closed, it should not be forgotten that under such circumstances but a small amount of force would be needed to effect a passage into cellular tissue or elsewhere in this immediate neighborhood.

At all events, this case, if not unique, is so interesting and instructive that no apology is needed for occupying so much space with its history.

THE OPERATION for the removal of this polypus was also no less profitable than interesting, because, in addition to errors committed in operating, and, of course, carefully avoided ever after, all my subsequent experiments towards devising a more powerful and yet portable battery than had been generally used heretofore, were prompted by what was observed on this occasion. In the first place, though the battery employed was one of huge dimensions, the thickness of the wire which it was capable of heating was quite insufficient to thoroughly cauterize the tissues in its passage through the pedicle; secondly, I contracted the loop too rapidly; and lastly, to make the matter still worse, traction was made on the tumor, so that, like ripping a seam in cloth, while some of the fibres were cut, many were barely touched with the heated wire.

The consequence of all this was, that my patient narrowly escaped death from hemorrhage. One large artery had to be ligated, and the vagina was tamponed with oakum soaked in persulphate of iron.

On account of this latter objectionable application, of which I can conceive nothing more filthy and abominable under all circumstances as a uterine or vaginal styptic, the cut surface was slow to heal, yet the patient was discharged well within a month from the date of her admission.

She has since given birth to her fourth child, and is in the enjoyment of perfect health at present.

This case is suggestive of many pathological theories and speculations; but the limits of this paper will not permit me to say more than that I believe the formation of this polypus commenced in the cervical canal before or soon after conception; that its growth took an upward direction; and, as the development of the uterus was proportionately greater and more rapid than that of the tumor, there was thus ample room afforded for its safe accommodation during gestation.

CASE XVII.

AMPUTATION OF CERVIX UTERI FOR HYPERTROPHY AND PROCIDENTA, RESULTING IN PERMANENT ELEVATION OF THE UTERUS.

Mrs. ——, aged 35, has had five children, the youngest 3½ years, and one miscarriage about three years previous to my seeing her, which was on December 16th, 1870. Complained of severe and constant backache, bearing-down pains, leucorrhœa and vesical tenesmus. Menstruation regular, though somewhat painful, and occasionally in the intervals more or less muco-sanguineous discharge, especially after long standing or fatiguing exercise. On examination per vaginam, the uterus was found low down, immediately within the vulvar outlet, and the cervix much enlarged, irregular in form, and tender. Os tincæ sufficiently open to admit the point of finger, but not further dilatable on account of the swollen condition of surrounding tissues.

The vesical wall was dragged down to such a degree as to constitute cystocele when the patient stood erect. The finger, on being withdrawn, was covered with a sanious mucus. The speculum being now introduced, the appearance of the organ was such as might be expected, the cervix fully two and one-half inches in diameter, purplish-red, and lobulated. The sound passed to the extent of four inches, and in such a direction as to show some degree of anteversion with slight flexion; but by conjoined manipulation it was evident that the great depth of the uterus was due to the increased size of its cervix, and that there was little or no corporal hypertrophy.

After a few months' treatment, consisting principally of warm vaginal douches, iodo-glycerine to cervix, a Hodge's pessary, etc., the uterus improved greatly, and she stopped visiting the out-door department of the hospital for some time.

Jan. 4, 1872, she applied again for advice, and stated that her former improvement did not continue long.

Her general physical condition was now much changed for the worse, and she had had several attacks of protracted menorrhagia since last seen. The depth of the uterus was four inches, and, except that the most gentle introduction of the sound caused hemorrhage from the cervical membrane, the parts presented an appearance very similar to that first observed.

She was advised to come into hospital for operation, and did so on Feb. 2, 1872, when it was decided to remove the whole cervix close to its vaginal insertion, by galvano-cautery, and subsequently, when the parts would heal, to take away portions of the anterior vaginal wall by Dr. J. C. Nott's clamp-eraseur.

Operation.—By means of the small cautery-knife (G) a circular fissure was made around the base of the cervix so as to form a bed for the wire-loop. The latter was next adjusted and the part to be removed securely embraced, while *slight* traction was made by means of vulsellum. (See Fig. 10.)

The battery connection being now effected, the loop was *slowly* contracted, so as to occupy not less than eight or ten minutes in passing through, thereby avoiding hemorrhage. When the cervix was lifted out the stump was found to be deeply concave; and as there was no appearance of blood, neither tampon nor other dressing was applied.

During the three days subsequent to the operation, no special treatment was needed, as the patient felt no inconvenience whatever from what had been done.

About the fourth day—which I find is the rule in such cases—a copious discharge of healthy pus began to flow, and during the ensuing week the vagina was douched twice a day with tepid water and castile soap, and at a later period with a solution of sulphate of zinc and water (℥ i. to Oi.). An examination made on the 2d of March (four weeks after operation) showed the parts to be entirely healed, and the surface from which the cervix had been removed, *smooth* and covered with healthy membrane.

March 9th.—The patient was placed on the table, and anæsthetized previous to operating on the anterior wall, as above stated, my friend Dr. Nott and the members of the hospital staff being present, when, to the surprise of all, the following condition of things was observed: *There was no bulging of the vesico-vaginal septum, and the uterus was with difficulty reached by the finger, as if the vaginal canal had been stretched in an upward direction. The uterus was not alone elevated, but no reasonable amount of traction, by means of a vulsellum, could move it from its lofty position.* No further operations being indicated, she was soon after discharged cured.

This remarkable degree of fixation of the uterus, fol-

lowing amputation of its cervix by the electric cautery, is a clinical fact worth bearing in mind, especially as neither fever, pelvic or abdominal pain, nor, in fact, any other symptom indicative of inflammatory action, followed the operation. However, there cannot, I think, be a doubt but that it was due to some local inflammation of a subacute form in the areolar tissue and lymphatics of the broad ligaments, resulting in a tightening or abnormal inelasticity of the uterine supports.*

CASE XVIII.

INTRA-PELVIC FIBROID.—THIRD OPERATION ON SAME PATIENT.

The young lady whose case has already been fully given (Case XIII), having entirely recovered from the severe ordeal undergone in August last, and having suffered much of late from vesical tenesmus, occasional retention of urine, and other distressing effects of pelvic impaction, was induced to submit to a third operation on first of the present month (December). This consisted in the removal of all that part of the tumor within the lower pelvis, the presence of which was the cause of all the suffering now complained of. A large-sized hard rubber crochet-needle, rounded at the end, was heated and slightly bent so as to accommodate itself to the curve of the sacrum and posterior contour of the tumor.

A small hole was drilled transversely near its distal extremity, and at right angles with the direction of its curve, and through which a stout platina wire was passed half its length. The free ends of the wire were now passed through two copper tubes, each $\frac{1}{16}$ of an inch in diameter, and eight inches long, and bent to nearly the same form as the rubber rod (Fig. 16).

An anæsthetic having been administered, and the patient placed on her left side, the two tubes with the rubber rod between were carried behind the tumor and as far up as deemed safe.* The rubber support being now entrusted to an assistant, and maintained steadily in position, one of the copper tubes was carried around half the circumference of the tumor, the wire being pushed up, piece by piece, from below, and when the centre anteriorly had been reached, was so held until the opposite half had been encircled in like manner. Two small pieces of wood, each one inch

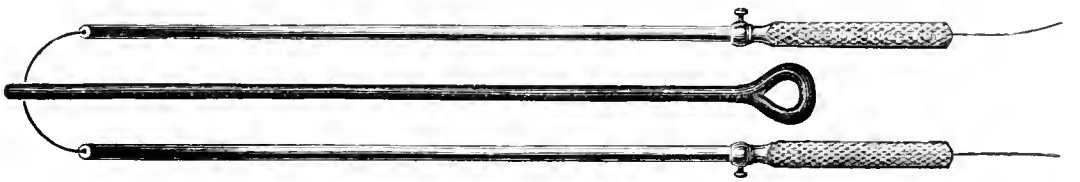

Fig. 16

and a half in length, flat-oval, and having two holes running through longitudinally for the reception of the and the excision of which at an earlier period did not seem warrantable on account of her weak condition.

The part now referred to may therefore be considered as the stump from which the large mass was taken on the former occasion. It does not seem to have increased in size during the last three months, though its presence has become more and more painfully felt of late. The upper two-thirds of the pelvic cavity was tightly packed, but the inferior portion towards the vaginal outlet was less crowded, principally on account of the globular form of the stump. The latter was perfectly smooth, and presented no appearance of having ever been an open granulating surface or being covered with cicatricial tissue.

In reflecting over the measures suggested to my mind for accomplishing its removal, either of two methods appeared practicable,—to repeat the operation first resorted to, by splitting the mass into two parts, and then looping either half; or to attempt its removal in one piece by a loop thrown around the whole circumference of the tumor.

On account of the great length of time occupied, however, not to speak of the almost insurmountable trouble and difficulties experienced on a former occasion, the first of these plans offered but little attraction; and though it seemed at first impossible to devise any means by which a smooth globular mass might be embraced by a wire noose, I decided to make the effort.

The method practised may be described as follows: copper conductors, were one after the other slipped up so as to unite, yet insulate the latter.

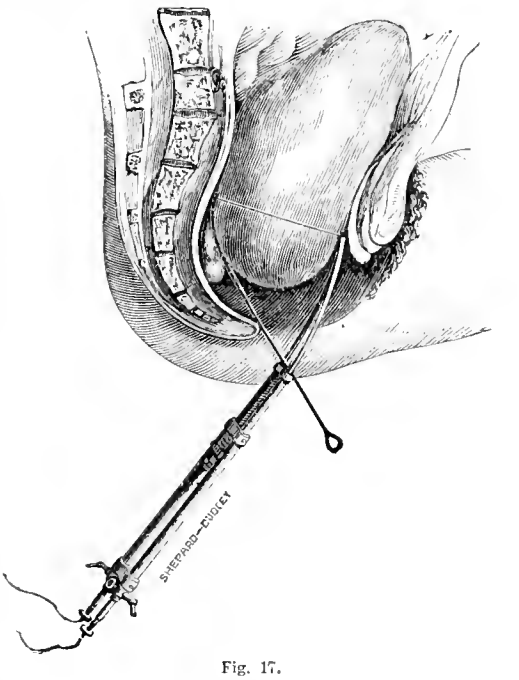

Fig. 17.

* In procidentia, where amputation of the cervix is called for, would not the introduction of a cylinder speculum after operation, and its retention for eight or ten days, insure a permanent elevation of the uterus, and provide against relapse of other parts?

* Fearing that some abnormal position of the Douglas *cul-de-sac* might exist, the part selected for looping was some distance below the fornix vaginæ.

This being accomplished, the free ends of the platina wire were next passed through a modification of the loop instrument as shown in Fig. 2, and the copper conductors firmly fastened in the socket. All being now in readiness, the battery connections were made, when the heated wire cut through the rubber support and embedded itself in the substance of the tumor.*

The rubber rod was now withdrawn, and the loop *very slowly* contracted, the time occupied in cutting through the whole mass being fully thirty minutes, exclusive of necessary interruptions. There was no hemorrhage from the stump, but the vagina was tamponed as a precautionary measure.

Reaction after the operation was, in this instance also, quite satisfactory; and though her pulse for several days did not get below 110, she expressed herself as feeling very comfortable and free from abdominal pain or tenderness. The vaginal dressings were removed on the third day, and the parts well bathed with tepid soap and water; to which was added carbolic acid. Copious discharges of healthy pus now appeared, the vagina was douched several times a day, she enjoyed and retained her nourishment and stimulants, and everything progressed favorably up to the night of the 10th, nine and a half days after the operation. On that night the weather suddenly became intensely cold, and being nervously apprehensive that urine might accumulate in the bladder so as to require the use of a catheter, she persisted in getting out of bed a number of times to pass water.

At an early hour of the morning of the 11th, Dr. Schapps saw her, was told she had several chills, and recognized well-marked symptoms of incipient tetanus. This condition of things rapidly became worse, and though every means at our command was promptly applied and persevered in, no amelioration of her spasms was effected thereby, and she died at four A.M. on the 14th.

Autopsy.—An incision was made from the ensiform cartilage to the symphysis pubis, and the integuments dissected from the latter preparatory to its removal. This being effected, a careful inspection of the abdominal and pelvic contents *in situ* was thus afforded. There was almost a total absence of adhesions, or any evidence of recent or remote peritoneal inflammation. The ovaries were small and shrivelled, but healthy, and the tubes, with their peritoneal attachments, were free and in other respects normal.

The utero-ovarian plexus of veins on right side was in a varicose condition, and one fully as large as the jugular issued from the outer circumference of this varix, and passed directly upward to a point opposite the gall-bladder, where it entered the ascending cava. The fundus uteri was cup-shaped, as if partially inverted; the bladder was healthy; and the peritoneal surfaces all over remarkably pale and free from lymph deposits. The anterior vaginal wall, of which the uterus seemed to be a continuation, was next slit up to within an inch and a half of the fundus, when the partial inversion referred to became still more manifest, and was exactly central, each tubal opening being the lateral boundary of the depressed part.

*The tumor was now found to be not interstitial, but connected to the uterus by two separate attachments: one, the pedicle proper, springing from the right wall below the Fallopian opening, in diameter about two inches, and short; the other covering a great portion of the opposite side, and extending down the cervix to its junction with the vagina.**

This latter connection was evidently secondary, and the result of inflammatory action at some remote period. The vaginal surface of the tumor, from which a part had been excised, was covered with healthy granulations and the healing process remarkably far advanced considering the short time that had elapsed since the operation. The post-mortem tumor was not weighed, but appears to be not quite twice the size of that removed by the last operation.

(To be continued.)

* On account of the length of wire required to encircle the tumor, two batteries were connected and used until a part of the mass was cut through, after which one was found sufficient.

* This adhesion of the tumor to the left side of the uterus, undoubtedly resulted from the first attempt made at enucleation in September, 1869.

ADVANTAGES OF THE VERTEBRATED CATHETER IN PROSTATIC RETENTION.

By T. H. SQUIRE, M.D.,

ELMIRA, N. Y.

In his late and very valuable work, "The Principles and Practice of Surgery," Prof. Hamilton, speaking of my new prostatic catheter, says: "I have employed this instrument in a few cases, and have found it to answer its purpose exceedingly well; but, notwithstanding the assurances given by the inventor, it is impossible to divest one's self of an apprehension that the links may become detached and remain in the bladder; nor is it plain what advantage this instrument can possess over the ordinary flexible catheter, when the shaft has been rendered firm and the vesical extremity more flexible, in the manner which has been already described." The description referred to reads thus: "There is also a very simple expedient to which I have resorted in these, and in many other cases, with remarkable success. Having dipped the end of the gum-elastic catheter in hot water to render it more flexible, it has been introduced to the obstacle, and the stylet then withdrawn an inch and a half or two inches. By this manœuvre the end of the catheter is still more elevated, while it is so flexible as to assume any direction which the channel may happen to require. The outer end of the catheter is now seized and pushed down on the stylet, while, almost at the same moment the stylet itself is gradually withdrawn. Care must be taken, in adopting this method, that the stylet is withdrawn in the first place so far as to render it certain that the extremity cannot protrude from the eye of the catheter."

I trust I shall now be able to show what advantages the vertebrated catheter possesses over the ordinary flexible catheter, when employed in the manner here described. In the first place, the care required to have the stylet so far retracted as to render it certain that the extremity cannot protrude from the eye of the catheter, and the care and skill required in gradually withdrawing the stylet itself almost at the same moment that the catheter is pushed down on the stylet, are entirely dispensed with when the vertebrated catheter is employed; and when the result of an operation depends upon the exercise of care and skill, it is not so likely to be successful as when the result does not depend upon elements so apt to be deficient in a large proportion of operators.

As to the special directions which the distinguished author here gives in respect to the management of the ordinary flexible catheter, we may very properly de-

vote to them a close and careful consideration. He says: "By withdrawing the stylet an inch and a half or two inches, the end of the catheter is still more elevated, while it is so flexible as to assume any direction which the channel may happen to require." The first part of this statement is true. That is to say, when a styletted gum-elastic catheter has become arrested at the prostatic portion of the urethra, if the stylet be retracted in the direction of its shaft for a distance of one inch and a half, the beak of the catheter, if it were allowed by the anatomy of the patient to obey the effect of this retraction, would be elevated a distance of nearly three inches, passing in a straight line to a point external to the body, about one inch above and in front of the pubic arch. But, owing to the anatomy of the patient, the beak, under these circumstances, can only be elevated from the posterior to the anterior wall of the canal, and this, of course, is all the elevation required. To effect such an elevation of the beak, the stylet only requires to be retracted about one-fourth of an inch. When the beak is thus elevated, the catheter may be advanced till the beak again strikes the posterior wall. Another retraction of the stylet, about one-fourth of an inch, will bring the beak a second time in contact with the anterior wall of the urethra, and then a second advance of the catheter may be made; and this double process of retracting the stylet and advancing the catheter, will, by quarter-inch stages, generally conduct the beak into the bladder. These separate acts of retracting the stylet, and of advancing the catheter, may be performed alternately, or, if the operator be very skilful, they may be accomplished simultaneously, and by a continuous movement of the stylet backward and the catheter forward. I have myself, from experience in years past, learned the value of this manœuvre. It answers well in skilful hands, when the obstruction is at the posterior wall of the urethra; but it is of less service, or of no service at all, when the obstruction is differently situated, as it sometimes may be.

The other part of the statement, "while it is so flexible as to assume any direction which the channel may happen to require," must be taken with some limitation. Dipping the end of a gum-elastic catheter in hot water—temperature, say, of 150° or 175° Fahr.—does render it more flexible than it would be at the common temperature of our apartments; but if we confine our attention to the vesical one inch, or one-half inch of the catheter, we do not, even at the moment of withdrawing it from the hot water, find it "so flexible as to assume any direction which the channel may happen to require."

Although the deeper part of the urethra is virtually a rigid canal, yet it is lined by a soft and very delicate membrane which will bear but very little pressure without injury. An instrument that can of itself follow the curves of this portion of the urethra, without inflicting injury upon its lining membrane, must have a lateral instability—flexibility—which is delicate in the extreme. Such flexibility the gum-elastic catheter does not possess, even at the temperature of 170 degrees. But, even if such were the case, however expeditious the operator may be, the catheter, thus previously dipped in hot water, is sure to become of the same temperature as the body before the time arrives for retracting the stylet. All arguments, therefore, in favor of the gum-elastic catheter must be based upon the degree of flexibility which it possesses at the temperature of the human body; and at this temperature, if we confine our attention to only one inch in the length of the tube, it may with more propriety be called a *rigid* than a flexible catheter.

Moreover, if the gum-elastic catheter did possess, at the time of use, the degree of flexibility required by the exigencies of the case, this very circumstance would deprive it of that *longitudinal stability* which is a very important requisite in a prostatic catheter. In such a condition the gum-elastic tube might double on itself in the canal, and there would be nothing to prevent its walls coming in contact with each other, and thus obliterating the calibre of the instrument.

Another objection which might be named is the impossibility of giving to the gum-elastic catheter so hard, smooth, and acceptable an external surface as can be secured by the use of silver as the material for making the instrument. The difference in this regard is quite important in respect to the precise form and finish of the beak. A prostatic catheter should not only have a perfectly smooth external surface, but its beak should be *exactly* hemispherical in form. In these particulars of surface and form, it is very difficult to give a perfect beak to a gum-elastic catheter.

Considering now the attributes of the vertebrated prostatic catheter, we find it possesses—chief of all requisites—in its vesical extremity the most delicate lateral instability. This essential quality does not depend upon the elasticity of the material of which it is made, but it is the resultant of a series of perfect joints. The first joint is only one-fourth of an inch from the beak. It is ball and socket in principle, and, with the least possible degree of friction it allows the beak to turn, in any direction, fifteen degrees from the axis of that part of the instrument with which it is joined. The remaining joints are precisely similar to this. They are eleven in number, and only one-fourth of an inch apart. The delicacy of the flexibility thus obtained is strikingly illustrated by the spontaneous bending of the instrument under its own weight. Of this catheter it can, of truth, be said, "it is so flexible as to assume any direction which the channel may happen to require." With this quality of extreme flexibility, it possesses every other essential requisite for a prostatic catheter. It has a good calibre, smoothness of external surface, hemispherical beak, longitudinal stability, inability to double on itself in the canal. In use, the surgeon has only to oil the instrument and push it gently along the urethra. When it reaches the point where other instruments are so apt to stop, the slightest pressing of the posterior wall of the urethra upon the circular shoulder of the beak causes this to be elevated, the flexion taking place at that joint which is only one-fourth of an inch from the end of the catheter. The surgeon, meantime, exercises no care or skill, save that which is necessary to move the instrument along the canal. The elevation of the beak, which has just taken place, brings the axis of the terminal quarter-inch of the catheter into proper relation with the axis of that part of the canal which is immediately before it, and there is no impediment to advancement. If, further on, there is undue pressure from the posterior wall of the urethra, the beak is again elevated, and again the terminal quarter-inch of the catheter is in conformity with the direction of that part of the canal which is immediately in its front; and thus it is that the simple pressure of the urethral wall upon the shoulder of the beak causes the end of the catheter always to be properly directed on its course. The same influence which causes the beak to obey all the curves of the urethra, causes each succeeding section of the instrument to follow in the wake of its antecedent; and in this simple, easy, expeditious manner, almost before the surgeon or the patient is aware of it, the bladder is entered and the desired relief obtained. And this is the result *in every case*

where the urethra is not actually strictured or blockaded by a virtual right angle. This statement would seem presumptuous if statistics, in over fifty cases of prostatic retention, did not warrant the assertion. And yet the conclusions drawn from theory, when correctly understood, are in strict harmony with the irresistible logic of these facts. Is it a thing inconsistent with reason that a hollow instrument can be made, every time, to go through a canal eight inches long, open at both ends, and not strictured in the middle? No surgeon doubts the possibility of passing a rigid silver catheter from the meatus externus to the membranous portion of the urethra, *in every case* where the canal is free from stricture. This feat is always easy of accomplishment, because the *urethra*, thus far, "is so flexible as to assume any direction which the *catheter* may happen to require." Now the counterpart to this law of physics furnishes the proof, in theory, that the vertebrated instrument will traverse the remainder of the urethra in every case where neither stricture nor right angle exists; for here the *catheter* "is so flexible as to assume any direction which the *urethra* may happen to require." And right here, by way of parenthesis, I cannot refrain from inserting a few simple axioms, in physics and in motion, which are of fundamental importance in respect to the subject of catheterism, but which, probably on account of their very simplicity, have never been systematically expressed in any standard work on surgery. They are as follows:

1. A rigid canal that is straight, may be easily traversed by a rigid instrument that is straight.

2. A rigid canal that is straight, cannot be traversed by any rigid instrument that is not straight.

3. A rigid canal that conforms to the arc of a circle, may be easily traversed by a rigid instrument that conforms to an arc of the same circle.

4. A rigid canal that conforms to the arc of a circle, cannot be traversed by any rigid instrument that does not conform to an arc of the same circle.

5. Any rigid instrument may easily traverse a perfectly flexible canal.

6. Any rigid canal may be easily traversed by a perfectly flexible instrument.

7. A perfectly flexible canal may be easily traversed by a perfectly flexible instrument.*

It seems to me that the foregoing considerations are conclusive, and that they ought to convince any one of the decided advantages of the vertebrated prostatic catheter. It may not be possible by mere theorizing to induce absolute conviction; but facts are invincible, and statistics have shown this catheter successful in the highest degree, in very many cases where all other catheters had signally failed.†

But Professor Hamilton says: "It is impossible to divest one's self of an apprehension that the links may become detached and remain in the bladder." And it must be confessed there is considerable ground for this apprehension, nevertheless, if the instruments are manufactured in the most perfect manner, and if due care is exercised in their use, an accident of this kind ought very seldom if ever to occur. As the catheter is now made, any person can take it apart for inspection, and put it together again in less than one minute of time; it must therefore be distinctly understood, that in case such an accident ever should take place it will be the fault, not of the instrument, but of the person using it. Furthermore, if the future should prove this instrument more liable to the accident named than other instruments are—for it must not be forgotten that fragments of other catheters have not unfrequently been left in the urinary bladder—the misfortune may very properly be set over against perforation of the urethra, and unrelieved retention, so frequently chargeable to the rigid instruments. The common silver catheter and even the gum-elastic with its stylet, have perforated the urethra much more frequently than the profession have been willing to admit. Professor Hamilton himself believes the common silver catheter manages to "tunnel" the urethra in about half the cases where it is used by druggists and empirics. Judging from my own observation and other reliable sources of information, I am satisfied that, even in the hands of inexperienced professional men, this accident occurs in a large proportion of the cases of prostatic retention. Nor has the peritoneal cavity always escaped the migratory excursions of the rigid catheter.*

These serious evils attending the use of rigid catheters could be more easily overlooked if, in connection with them, the relief sought could always be realized; but, unfortunately, the rigid instrument too often succeeds to do the evil, and at the same time fails to do the good. And this double misfortune, let it be borne in mind, is generally the fault, not of the operator, but of the instrument. It is to the credit of the vertebrated catheter, that the only accident that can result from its use must happen while its beak is in the bladder.

In cases of prostatic retention, let the physician using the new catheter be always sure that the flexibility of the vesical portion is perfect, that the links of the chain are safe, that the instrument is neither too large nor too small, and that the urethra is free from stricture, and then he will very seldom, if ever, fail in drawing the water.

* Of course it is to be understood, in each case, the instrument must in diameter correspond with the diameter of the canal.

† See *American Journal of the Medical Sciences* for October, 1871, and October, 1872.

BORAX AND THE NITRATE OF POTASS.

IN THE LOSS OF VOICE FROM "COLDS" IN PUBLIC SPEAKERS AND SINGERS.

By JOHN W. CORSON, M.D.,

ORANGE, N. J.

Some years since, while in charge of the class of "Diseases of the Chest and Throat," in connection with the New York Dispensary, at the suggestion of a non-professional friend engaged in teaching elocution, we were led to test the efficacy of borax, or the biborate of soda, in many cases of sudden hoarseness from cold. In mild attacks it often acted like magic. About ten minutes before any continuous effort at speaking or singing, a lump of borax the size of a garden-pea, or about three or four grains, was held in the mouth till it was slowly dissolved and partially swallowed—distilling, as it were, down the throat. For an hour or so it would frequently render the voice quite silvery and clear. For this purpose, we discovered that it possessed three special advantages. It was easily obtained, convenient to carry in the vest pocket, and perfectly harmless. Gradually, in private practice, we afterwards found that it was very serviceable to clergymen and singers who were subject to distressing interruptions from the above cause, on important occasions.

Borax thus slowly melted in the mouth till it distils down the throat, as any one in health may safely

* Complete notes of one such case, with post-mortem proof, are in my possession, and in this case the fatal injury was inflicted by a physician of ordinary education.

prove, stimulates the secretion of saliva and makes the whole mouth and throat "water" profusely. Physiologists tell us that the glottis, the organ of the voice, is both a stringed and wind instrument; and the action of borax in moistening its orifice and musical "strings" seems precisely like the "wetting" which restores the missing notes to a flute when it is too dry.

Let us not, in our interest in a "new remedy," for a single troublesome symptom claim too much. Many medicines, as we know, of much value are constantly abused by being misapplied. Neither in chronic affections of the throat, nor in acute inflammation or "tonsillitis," once established, have we found either borax or another remedy, which we shall presently mention, of any special efficacy as curatives. These cases require other appropriate treatment.

Returning again to the subject of a "common cold," we may allude to an agent for which in this special application—just as we were for iodine and ergot in other cases—we are indebted, so far as we know, to "popular tradition." An early friend and patient of ours, since deceased, a New York dock-builder, much exposed to the weather, claimed to have a secret remedy for "colds." But he was too generous to bury anything useful. At length he confessed that it consisted in covering up warmly in bed, drinking a glass of water, and sucking a piece of the nitrate of potass.—or "saltpetre," as he preferred to call it—the size of a garden-pea or a little larger, till it was slowly dissolved and swallowed. We think we improved his prescription by sweetening the water, to cover the mawkish taste of the "saltpetre," mixing them, and swallowing both together. We also increased the dose, from gratifying personal experience, to five grains. As a courtesy from our profession to clergymen and singers, we may suggest that they will find it very convenient in travelling, to carry a few five-grain powders of the nitrate of potass., prepared by the druggists for ready use. Like the borax, it relieves the dryness of the vocal cords. It is also easily obtained in every household, and, taken in the dose recommended, is quite harmless. With the help of the extra clothing and the glass of water, it excites for a whole night a gentle perspiration, and thus, *if taken at the very commencement*, "breaks up the cold." It accomplishes this as do warm foot-baths, with hot teas, or Turkish or Russian baths, if used early, by opening those millions of pores of the skin which Erasmus Wilson counted through his microscope. As the aching, the weariness, and the headache of a severe cold tell us, the blood is slightly poisoned by suppressed perspiration. And the simple lesson of cure is promptly to open these pores. We may add, that the efficacy of any of these remedies is much increased by putting on a warm shawl or great-coat, and throwing the arms about, and walking the floor rapidly till the hands and feet are in a perfect glow, before retiring to bed. If in a hotel, where the sheets may be damp, it is best by all means to have a fire in the bed-room and air them for an hour. We need hardly say that after any treatment of this kind, the patient should prudently wear an extra shawl or great-coat, and avoid standing in the street or exposure to the cold wind next day. Nor is this care in vain. The recent views of Niemeyer and others, as to the frequent inflammatory origin of tubercles in consumptives, have lent a new interest to neglected "colds."

By combining these two modes of treatment, by borax and the nitrate of potass., we have had the pleasure, within the last few years, of restoring to a number of clergymen and lecturers the lost gift of speech within twenty-four hours. Several of these recoveries were so rapid and complete as to be very gratifying. Not long since, a distinguished American lecturer, residing in Newark, was about to telegraph a disappointment the day previous from a severe cold, when he was persuaded to defer his purpose and try these restoratives. Next evening he delighted a large audience with a clear, ringing lecture, full of fine cadences, on the "Yo-Semite Valley."

This treatment has been equally serviceable to singers. We may give two illustrative cases. The lady soprano of a fashionable New York church had been engaged as the chief attraction of a musical entertainment in Orange. The day previous, in a choking, husky voice, she told the committee that she was too ill with a "cold" to sing. We urged her to try the above remedies. She consented. Next evening she rose like a lark in the grand solo from the Messiah, "I know that my Redeemer liveth."

A charming American vocalist, the gifted daughter of a New England physician, who will doubtless be well remembered by all who heard her as the companion of Nilsson at the Academy of Music, happened to be visiting her relatives in Orange. She called us to prescribe for a severe cold, which she feared would oblige her to give up a New York engagement. We directed her to use the nitrate of potass. and borax in order above mentioned. Next evening she sang sweetly as usual. The following week her friends received a slip from a Philadelphia paper, warmly eulogizing her "beautiful voice," and showing that the relief was permanent.

For clearness and convenience, we may sum up the results of our experience in the following brief conclusions:

1. That in sudden hoarseness or loss of voice in public speakers or singers, from "colds," relief for an hour or so, as by magic, may be often obtained by slowly dissolving and partially swallowing a lump of borax the size of a garden-pea, or about three or four grains, held in the mouth for ten minutes before speaking or singing. This produces a profuse secretion of saliva, or "watering" of the mouth and throat. It probably restores the voice or *tone* to the dried vocal cords, just as "wetting" brings back the missing notes to a flute when it is too dry.

2. Such "colds" may be frequently "broken up" at the very commencement; and this restorative action of the borax to the voice may be materially aided by promptly taking, the evening previous to a public effort, dissolved in a glass of sweetened water, a piece of the nitrate of potass. or "saltpetre" a little larger than a garden-pea, or about five grains, on going to bed, and covering with an extra blanket. The patient should keep warm next day. This both moistens the dry throat and further relieves the symptoms of "cold" and slight blood-poisoning from suppressed perspiration, by reopening the millions of pores of the skin more or less closed by cold.

3. These remedies have the three recommendations of being easy to obtain, convenient to carry in travelling, and perfectly harmless.

4. They are nearly or quite useless in the actual cure of long-continued chronic disease of the throat, or acute inflammation or "tonsillitis," both of which require other appropriate treatment.

Russian Alcohol.—Alcohol and brandy are largely manufactured in Russia from mosses and lichens. The quality is said to be exceedingly good.

CASE ILLUSTRATING THE ANTAGONISTIC EFFECTS OF ATROPIA AND MORPHIA, WITH REMARKS.

By FREDERICK D. LENTE, M.D.,

COLD SPRING, N. Y.

Mrs. O——, aged 48 years, in extremely feeble health and much emaciated from the effects of malarious fever of three months' duration, which had obstinately resisted the treatment of several physicians of good standing, applied to me October 14th, 1872. In connection with other treatment for the relief of obstinate vomiting, pains, and other troublesome symptoms, I injected four grains of *quinine* into the arm to break up the *tertian*. She visited me again on the 21st, stating that her vomiting had been arrested, that her other symptoms were somewhat better, and that her fever had been checked until the 19th, when she had a moderate attack. She was, however, very feeble, had eaten almost nothing at breakfast (it was now one o'clock P.M.), and her fever had evidently set in, as her temperature was 102 and skin rather warm; she felt faint and weary with travelling some distance, and then waiting for me several hours. With the view of breaking up the fever as rapidly as possible, and thus enabling her to travel to her home, I proposed to inject hypodermically four and a half grains of *quinine*, contained in fifty-five drops of a fluid, as was done at her previous visit. This was done at twenty minutes past one o'clock. In a few minutes after, she complained of being faint and dizzy, and asked for water. After resting for a few minutes she still complained, and said she felt as if she had taken too much wine. This surprised me, and on investigation I found to my horror that, by some displacement of my bottles of hypodermic fluids, I had used fifty-five drops of Fleming's sol. of atropia, with morphine added to bring it up to the standard of Magendie's sol. of morphia, thus making very nearly *two* grains of morphia and about *one-eleventh* of a grain of atropia. There was nothing to be done but to watch for the effects and endeavor to counteract them. From previous experience, I relied a good deal on the antidotal effects of the two poisons. But the exhausted condition of the patient, and the state of inanition at present existing, caused me to be fearful of a rapid absorption. Half an hour after, the patient walked with but little assistance out of the office, got into a light wagon, was driven one-third of a mile to the house of a friend, talking all the way quite rationally and composedly, and finally got out of the vehicle with but little assistance and walked into the house; at this time she complained of nausea and said she must vomit; but she did not, and the nausea did not recur. Pupils almost natural, a little dilated, perhaps; pulse good; respiration rather slow. 3.20 P.M., two hours after injection: Lying quietly in bed, eyes closed, but not particularly sleepy, and complaining of nothing but weakness, which she had complained of previous to the dose. Pulse 120, full and regular. Directed half an ounce of whiskey every half hour. Pupils more dilated, and acting rather feebly. 5 P.M., three hours and forty minutes after: Within the last half hour has lapsed into almost complete coma. With the greatest difficulty can be made to swallow a teaspoonful or so of eggnog. Has only had one ounce and a half of the stimulant. Respiration 4½ per minute, intervals irregular, but otherwise natural. Pulse 106, full and regular; skin natural in appearance and temperature. Pupils very slightly dilated and immovable; mouth is dry, and she had complained of this previous to passing into insensibility. Directed cool applications to head, and beef-tea and whiskey, an ounce of each *per rectum*, every half h. 7 o'clock P.M., five hours and forty minutes after: Was seen by Dr. A. A. Smith, late of Bellevue, who was assisting in my practice. Pulse 99, full and regular; respiration 5½, intervals very unequal, but otherwise natural; could be roused, with some difficulty, to comprehend a question. Pupils the same. 8 o'clock, six hours and forty minutes after: Is easily aroused, and says she feels "pretty well," in a very drowsy way. Pulse 90, respiration 8, fuller and more regular; can swallow eggnog without difficulty. Directed stimulants to be given less frequently. 11.15 P.M., nine hours and thirty-five minutes after: Dr. Smith was accosted by patient with "good evening" as he entered the door; she said she felt well, except that her head was heavy and her mouth dry; asked for a glass of water, and said she guessed she would go home in the morning. Respiration 9½ per minute; pupils responded very feebly to strong light.

October 23d, 9 A.M. Patient about in the same state as she was before the operation; pupils natural, and no symptoms referable to either opium or belladonna.

November 5th. In the afternoon of last date patient returned home, feeling no inconvenience whatever from her dose.

November 13th. I learned to-day from an acquaintance of the patient that she has been improving in health since the injection, probably in consequence of the interruption of her intermittent trouble, of which she has not since felt any symptoms.

Remarks.—The almost entire absence in this case of all the striking symptoms almost invariably present in belladonna poisoning, when not counteracted by treatment, is remarkable. The following account of the symptoms is given in a recent work: "Dryness of the throat, constriction of the fauces, difficult deglutition, indistinct vision or double vision, headache, staggering, and confusion of ideas, stammering, etc. The pupils are widely dilated, face suffused, lips livid, and pulse rapid and intermittent, delirium and deep coma." To which others have added "nausea and ineffectual retching, feeble pulse, excessive jactitation, &c.

In the present very unsettled *status* of the important question of the *antagonism of poisons*, I offer the foregoing case as a contribution which may materially aid in its solution so far as it relates to two most valuable drugs. The powerful poisons, all of them so uniformly destructive to man, have such varied effects on the lower animals as to render experiments, which have, of course, to be restricted to them, except through an occasional accident like the above, extremely uncertain. Thus there is scarcely a poisonous dose of arsenic for a dog, or of atropia for a rabbit; while if we reverse the poisons for the two animals both will speedily succumb. Careful experiments have appeared to demonstrate to different observers, that in dogs at least there is no antagonism betwen *morphia* and *atropia*,* while numerous instances have been recorded, showing that in the human subject there is a decided antagonism, though none, I believe, so conclusive as the case now presented. This is not the first instance, though the most striking, of this antidotal influence which has fallen under my personal observation. Some time ago I met with a case where, to combat most intense suffering and very alarming symptoms, three hypodermic injections of a solution of morphia and

* In fact, dogs, although frequently chosen for these experiments, are not at all fit subjects, since they bear enormous doses of morphia as of arsenic without injury.

atropia at short intervals were made, the aggregate amount of the solution being *thirty-five minims*, containing something more than one grain of morphia and one-sixteenth of a grain of atropia. In this case the phenomena, though very similar in some respects to those presented by the first-mentioned case, were very different in others. Thus, up to several minutes after the last (third) dose, no marked relief of the pain was noticed, when *suddenly* the patient lapsed into almost complete coma, which became absolute within half an hour. Nothing was done for this patient except to use injections, *per rectum*, of stimulants and beaf-tea moderately. The pulse was rapid after a time, but not alarmingly weak. It is worth noting, that in this case, as in that of Mrs. O., the comatose symptoms disappeared rather suddenly about six hours after the dose was administered. In this case, as in the other, the pupils were almost normal *in size*, and quite immovable under the stimulus of light. I would also call attention to the fact, as furnishing a hint as to the proper relative doses of the two drugs for the production of antidotal effects, that the dose of the atropia was *relatively* larger in this case than in the other, and its toxical effects also more apparent in the excessive dryness of the mouth and throat, thirst, etc., of which the patient complained after recovering consciousness, also the extreme debility which attended the slightest exertion for two or three hours. Patient also remained in a state of obstinate *insomnia* for twenty-four hours, and slept badly for several nights.

I have ascertained, by numerous trials, that if we use for ordinary hypodermic injections a solution of morphia and atropia of the strength of Magendie's formula for the first, and of Fleming's standard solution for the other, we will have the two drugs as equally balanced as possible; and we may safely inject as much as twenty *minims*, containing two-thirds of a grain of morphia and one-thirtieth of a grain of atropia without producing any of the toxical effects of either, and generally with the avoidance of the nauseating influence of the morphia; supposing, of course, that the amount of the solution injected is graduated to the amount of pain for which the morphia is indicated. If it is desired to give more of the morphia than is contained in twenty minims, it is safer perhaps to make the addition from a solution of morphia alone.

In a case of *stramonium* poisoning in a child to which I was called by Dr. Barker, now of Morristown, we used the hypodermic injection of morphia with prompt success. But it seems that the decided evidence of Stillé,* and the valuable article published by my friend Doctor Chas. Carroll Lee, then resident physician of Pennsylvania Hospital, in the *Am. Jour. of Med. Sciences*, January, 1862, in which he records and alludes to at least seven cases of his own, to thirteen cases cited by other competent observers, to "numerous cases" recorded by a physician of Brighton, England, and says that "others might be presented by the dozen if necessary," ought to set at rest this question. But still it remains, with perhaps a majority of medical men, an open one, and laborious experiments are still carried on in England and in this country on the lower animals, with the hope of arriving at some definite conclusions. One of our latest writers on the prompt treatment of poisoning† says: "Some recommend opium as an antidote; it has been successful in one or two cases." Of course we must expect to meet with an occasional failure, as we do with all remedies and all modes of treatment. Thus, Dr. S. D. Gross, in alluding to a case of fatal poisoning by opium to which he was called in consultation, where atropine among other remedial measures was employed, says that the latter seemed to increase rather than diminish the toxical effect of the opium. And Brown-Séquard believes, or did believe ten years ago, that there is no antagonism between the two drugs. But his opinion appears to have been based mainly on experiments on the lower animals—a most uncertain test. These experiments are, however, far from being valueless. Important scraps of information are being constantly accumulated in this way, the collation of which may at some future day settle many questions now in dispute. For instance, Dr. Fraser, of Edinburgh, has very lately ascertained a very singular fact, that although it requires twenty-one grains of atropine to kill a rabbit of medium weight, so small a quantity as 0.015 grain can neutralize the minimum fatal dose of physostigma; and that 0.1 grain is capable of antagonizing a dose of physostigma equal to three and a half times the minimum fatal dose of that poison.

The importance of this question is not by any means limited to the power which its settlement may afford us of saving life when all other means would be likely to fail, but extends to the treatment of disease in all its phases.

Dr. Fraser, in concluding his very able paper in the *Trans. of the Royal Soc. of Edinburgh*, remarks: "The existence of such an antagonism encourages the hope that the power of directly counteracting disease is far from unattainable; and it supplies a strong incentive to efforts designed to determine the conditions of disease, and the action of remedies, with an exactitude sufficient to show how the remedial action may be applied as a counteracting influence to the diseased conditions." In a hopeless case of cerebral disease in the child of an officer at West Point, to which I was called in consultation with the surgeon of the post not long since, and in which extreme contraction of the pupils was a marked and persistent symptom, though no opiate had been administered, I suggested, as a palliative at least, the use of belladonna in small and frequently-repeated doses. The effect was moderate dilatation of the pupils, with some temporary relief. I had forgotten at the time that Dr. Graves had, long ago, suggested that an agent which could relieve the contracted pupils, sometimes occurring in continued fever attended by coma, might also assist in the cure of the case; and that Dr. Anderson, of Edinburgh, had also advised that the state of the pupils, in certain desperate cases, be taken as a guide for the administration of opium and belladonna respectively. By experiment, as every one knows, it has been shown that the application of belladonna directly to the capillaries causes contraction, while opium largely dilates. And Brown-Séquard has proved that belladonna internally administered also causes contraction. In very obstinate and serious cases, then, especially of cerebral disease, attended by a marked and persistent abnormal size of the pupils, may we not with great propriety administer these powerful drugs which we know will entirely control the symptom, and probably the cause? I will conclude with citing one more case in point, where the poison was an animal one. The case is reported in the *Boston Med. and Surg. Jour.* for Sept. 30, 1869, from which I condense it: "A lad, aged 17, had been bitten by a rattlesnake. He was comatose, pale, and cold; lower limbs paralyzed; pulse 20 and very feeble; pupils largely dilated. At about 4 P.M. I gave pulv. opii. grs. ij.; at 6 repeated dose, pulse 32; at 8 repeated, pulse 50; at 10 repeated, pulse 65, slight perspiration; at 12 gave

* Therapeutics and Materia Medica.
† How on Emergencies, p. 216.

last dose, pulse 80, pupils now contracted to normal size. At about 3 o'clock patient waked up, as from a healthy sleep, and asked for something to eat; allowed him a good-sized meal." The reporter proceeds to remark: "One remarkable feature of the case was, that the opium at no time exerted its characteristic soporific influence.

An important question naturally comes up in connection with the above considerations, and ought to be briefly adverted to. What is to guide us in graduating the dose of these potent agents in those desperate cases where a mistake would precipitate the fatal result, and, at the same time, where timidity or hesitancy would be equally dangerous? In some of the cases of reported failure of the antidote it is very probable that the result was due to its too sparing use. Stillé is very decided and exact in his directions. "The dose can have no limit," he says, "but that of the active resistance of the morbific agent. Until this is neutralized, the remedy is little apt to become of itself aggressive and dangerous." "The condition of the pupil," he further says, "is an infallible index for the administration of opium and the mydriatics, in poisoning by one or the other of them. Until the contracted pupil begins to dilate, or the dilated pupil to contract, no danger from the antidote need be apprehended. Their antagonism is complete." These rules will probably hold good in poisoning by one or the other drug *alone*. But when powerful doses of the drugs combined are given, either accidentally or for the removal of certain conditions of disease, or in these days, when murder has become a science, for felonious purpose and to escape detection, we have the pupil perhaps normal in size from the exact balancing of the poisons, and immovably fixed. And yet for hours the coma may be complete, and the respiration down to 4½ or 3½ per minute, as I have seen in the two cases alluded to in this paper, and in one published by me in the *New York Med. Jour.* some three years ago. Here the danger seems imminent, and yet it is impossible to say which drug has the preponderance in keeping up the symptoms. We must then wait patiently and watchfully, taking the *pulse* as the principal guide, and using perhaps galvanism *moderately*, or artificial respiration, but avoid the perturbating treatment so commonly resorted to, and which so often quenches the spark which we should endeavor gently to fan into flame. In none of my cases, threatening as they appeared at one time, did I find any severe or extraordinary measures necessary.

Cold Spring, Dec. 17, 1872.

Progress of Medical Science.

Anæmic Murmur.—James H. Hutchinson, M.D., Physician to Penn. Hospital (*Phila. Med. Times*, Aug. 1872), in a clinical lecture on "Anæmia," stated that he had not been able to find a wholly satisfactory reason for the distinctness of the anæmic murmur at the base of the heart when the patient was lying down. It has seemed to him probable, however, that it might in some way be connected either with some altered relation of the heart to the great vessels at its base, or else with the restraint which the recumbent position exercises upon the freedom of the respiratory movements.

The Malignant Lympho-sarcoma.—Langhans, of Marburg, has made some valuable investigations, tending to define more closely what have been known variously as the lymph-adenomata, the condition known as anæmia lymphatica, leucæmia, or leucocythemia.

He gives the name of lympho-sarcoma to two forms of morbid appearances formerly grouped under the general name of leucæmia, but which both differ from lucæmia proper, in showing no undue proportion of white corpuscles in the blood. In other respects, excepting only that a fatal issue may be expected earlier, the two forms of lympho-sarcoma are not very different from lucæmia. In all three forms there are metastatic changes, and the liver and spleen are affected. In leucæmia, an increase in the number of white corpuscles of the blood has been shown to be so great that they may form one-sixth, one-half, or even a greater portion of all the blood-corpuscles. A similar increase in the blood-corpuscles in lympho-sarcoma has been suspected but never shown. L. divides these latter affections into two classes, the *hard* and *soft*, and gives the following differential points:—

1st.—In the *hard* form, usually, the lymphatic glands lying most superficially are the first seat of disease.

2d.—The *hard* is distinguished from the *soft* by its tough fibrous consistence, and this is regarded as a prominent characteristic.

3d.—Microscopically, in the *hard* form there is hyperplasia of the spleen-follicles and lymphatic structures generally, with excessive development of the connective tissue reticulum of the glands. When the spleen is affected most of the cells are very similar to the normal lymph-corpuscles. But there is also an admixture of giant cells and dark protoplasmic matter, containing numerous nuclei. The *hard* form has but slight tendency to inflammation and abscess, and is seldom the seat of cheesy degeneration and softening. It is usually not painful to the touch and not the seat of periodic pain. Its firm consistence, the absence of periadenitis, and the symptoms already described separate it from scrofulous swelling of the glands.

In tubercular changes with which this form of sarcoma has been seen to be associated in children the same microscopic elements are observed, but the disposition is different. In the sarcomata the connective tissue prevails, principally at the periphery, while the cells are most numerous at the centre. The converse is the case in tubercular induration, or if the cells are not most numerous at the periphery, they are in the intermediate zone.

Usually the disease commencing in the superficial groups of glands, those of the neck being most frequently elected, passes over, after weeks or months, to the groin or axilla. Later, those glands lying in the course of the great vessels take on the change, but the most constant lesion is of the provertebral lymphatic chain. Later still, when the spleen and the greater portion of the entire lymphatic system has become involved, disturbances in nutrition are shown. There are usually no subjective symptoms associated with the first appearance of the swelling. The prominent symptoms of general infection are a preternatural paleness of the skin, rapidly-increasing emaciation, muscular debility, rapid pulse with normal temperature, palpitation of the heart with systolic murmur at the apex, profuse bleeding at the nose, and dyspnœa. At the last there is usually œdema of the lower extremities and effusion into the serous cavities.

These unfavorable symptoms may increase in intensity, and the fatal issue may be a few months after the first appearance of the tumors, or the patient's life may be prolonged several years.

In no case has a favorable termination been observed. Preparations of iodine and of iron have had a transitory effect in arresting or diminishing the bulk of the

tumors, but relapses here invariably occurred. Repeated extirpation seems to have had no influence in retarding the course of the disease. This form of lympho-sarcoma must accordingly be classed among the most dangerous of new growths.

The name of anæmia lymphatica given by Wilks is rejected by Langhans, for the reasons given, that there is no abnormal increase in the number of the white blood-corpuscles.

The changes really consist in a paucity of blood, which is mostly non-coagulable, and resembles weak claret in fluidity and color.

The heart is usually found to be fatty. This condition, together with the changed character of the blood and the pressure of enlarged glands in the œnis, may account for the œdema.

In a similar way, pressure upon the bronchi and biliary ducts may explain the dyspnœa in part and the icterus.

Thus far the number of recorded cases is so small that statistics are valueless. It seems to affect the young by preference, and has been seen in children under ten years of age. Males have it more frequently than females.

Persons otherwise healthy are more frequently attacked than others of delicate constitution.—*Algemeine Med. Centr-Zeitung.* No. 77, Sept., 1872.

Uterine Inflammation and Defective Involution of the Sexual Organs subsequent to the Change of Life.—Dr. Tilt thinks physicians generally have made a great mistake in supposing that with the menopause would come, in every case, complete immunity from uterine diseases to women whose lives had been tormented by this class of affections; and that they are themselves in great measure responsible, since they have, by carefully dinning the above statement into their patients' ears, prevented many women from seeking advice when, after the menopause, a considerable amount of pelvic heat, pain, and muco-purulent vaginal discharge denote vaginitis and endo-cervicitis. And it is often only after these symptoms become sufficiently acute to completely interfere with the duties of life that they apply for relief.

He has seen but two cases in which severe endo-cervicitis has occurred after the menopause in women who had *never* previou-ly suffered from uterine inflammation, and admits that we are justified in asserting that congestive and inflammatory diseases of the womb are effectually barred in women who have never suffered from them previous to that period.

The physiological atrophy which occurs at this time in healthy uteri does not always take place when the organ has been diseased. The presence of an intramural fibroid, or a polypus in the cavity, or a condition of hypertrophy or fibroid degenerescence of the cervix, may interfere with this physiological atrophy for ten or fifteen years, and during this time the woman is liable to inflammations of the sexual mucous membranes, although to a less extent than menstruation acts as a disturbing element.

When, as in some instances, it occurs, involution does not take place uniformly, and there remains, after the menopause, a remnant of internal metritis while the cervical canal is healthy, the latter may shrink so that the fluids secreted by the diseased membrane lining the cavity are with difficulty expelled, and a considerable degree of uterine tormina is caused. Such cases were described by Dr. Matthews Duncan as "leucorrhœa of old women." Dr. Tilt has seen only five of these during twenty years, and, unlike Dr. Duncan, has never had occasion to resort to puncture in order to evacuate the retained fluid.

The only disease he has found to be at all common after the menopause is a more or less acute endo-cervicitis and vaginitis, sometimes existing together, sometimes singly, the latter being sometimes caused by the discharges from the former or by the extension of ulceration.

The presence of an ulcer on the cervix may give rise to no serious symptoms, but will serve to indicate the presence of a similar morbid state of the cervical canal which requires treatment.

These affections are less acute and painful than when they occur prior to the menopause, but are correspondingly more difficult to cure. While heteromorphous tissues may grow rapidly after this period, inflammation is singularly chronic.

When he finds that a patient has a hard and enlarged cervix, instead of encouraging her to believe that, with the cessation of menstruation, are to cease her sufferings, he takes care to predict occasional relapses for many years to come, which relapses may sometimes be attributed to a chill, to overwalking, or to too frequent coition. And he has observed that, in some patients, the spring and autumn are the periods when these attacks recur.—*Br. Med. Jour.*

The Cure of Stammering.—The mode of treatment followed by M. Chervin, of Lyons, in this affection, has lately been the subject of investigation by a commission appointed by the Department Council. The commissioners state that they find the system successful, rapid, and permanent in its effects; which opinion confirms those of earlier date, given by commissions appointed in France, Belgium, Spain, etc.

Eight patients, severely affected with stuttering, were submitted, under the observation of the commissioners, to the system of M. Chervin. They varied, in age, from ten to twenty-nine years, and none of them could speak without stammering to an extent most distressing to themselves and to those who heard and saw them. In some cases the act of speaking was accompanied with convulsive movements of the mouth and eyes; in others with spasmodic respiratory movements. Some had stammered from their infancy; in others the defect had been caused by a shock to the nervous system. Ten days after they had been placed under M. Chervin's treatment they were seen by the commissioners, and each of them could then speak distinctly without stammering or hesitation; and, on the 28th, they were pronounced cured, speaking then with natural ease and rapidity.

The system is as follows. All mechanical contrivances are discarded; but he teaches the patient, by means of a large number of exercises, gradually to pronounce with distinctness vowels, consonants, syllables, and sentences. He pays great attention to the act of respiration, which he seeks to regulate. He teaches his patients to take, at certain interva's, a slow but normal inspiration, which is succeeded by an even, continuous, and loud expiration, during which pronunciation is effected. The course of treatment occupies twenty days, the time being divided into three periods. During the first the patient is restricted to complete silence, so that the old habit may be broken; during the second period the patient is taught to speak slowly and deliberately; and during the third period he acquires the practice of speaking fluently and without clipping the words. This method is stated to have succeeded in the most difficult cases, and the good results are said to be permanent; but this greatly depends on the patient, who must occasionally make use of the means which were first used to cure him.

Danger of Morphine Injections with Chloroform Inhalations.—A good deal has been written about the union of morphine injections with chloroform inhalations to produce prolonged insensibility to pain after important surgical operations. M. Demarquay concludes, from a short series of experiments, that it is a method liable to especial dangers, arising from lowering of the temperature.

Exsection of the Fibula and Loss of Tendo-Achillis.—K. T. Coleman, M.D., formerly Chief Surgeon of Stonewall Division, C. S. A. (*Nashville Jour. Med. and Surgery*, October, 1872), mentions the case of Gen. Edward Johnson, who was wounded at the battle of McDowell, May 8, 1862, by a ball passing through the tendo-achillis, an inch above the level of the malleolus, leaving a mere shred of the tendon on either side, then ranged obliquely upward and outward, carrying away about half an inch of the fibula, about two inches above the malleolus, and splitting the upper fragment for an inch and a half. Amputation was not performed. He exsected two inches of the fibula, and removed the softened tendo-achillis. The wound upon the calf was dressed with a solution of sulphate of zinc and laudanum, and otherwise the limb was placed upon a double inclined plane, and treated as for compound fracture. The discharge was controlled and healthy action established by various lotions of sulph. zinc, sulph. copper, etc., but of this class there was no agent more valuable than the lotion recommended by Sir Astley Cooper—three drops of strong sulphuric acid to the ounce of rose-water. The limb was moulded, and the gastrocnemius, deprived of the antagonism of the tendon, was kept in *situ* by well-adjusted adhesive strips. In six months General Johnson returned to duty, and was in active service until the close of the war.

Some sort of tissue supplied the place of the lost tendon; the ligamentous material that filled up the hiatus in the fibula ultimately became ossified, and to-day the General walks as well as he ever did in his life.

Stone in the Bladder.—George E. Fenwick, M.D., Surg. to the Montreal Gen'l. Hop'l (*Canada Med. and Surg. Jour.*, October, 1872), in a paper read before the Canadian Medical Association, reported sixteen cases of stone in the bladder removed by the lateral operation, with satisfactory results. The detailed cases, with one exception, were children ranging from two and a half years up to thirteen years of age. Stone in the bladder is, in Canada, a comparatively rare disease; but it has been observed more frequently of late years in Montreal than formerly.

Dr. Botsford expressed an opinion that the ailment of stone in the bladder was very rare in New Brunswick.

Dr. Grant, President, observed that in Ottowa, during a period of thirty years, there had only been three cases of stone in the bladder. In one case, at the Catholic Hospital, no less than eighty-nine calculi were removed at one time.

Dr. Hamilton believed that in Nova Scotia the disease was still more rare than in New Brunswick. In a practice of thirty-eight years, in a growing town, in the County of Kings, he had never heard of a case. Their soil was based upon sandstone, and the water was good.

Extract of Eucalyptus.—According to the *Pacific Medical and Surgical Journal*, cigarettes of the leaves of eucalyptus globulus have been prescribed, with advantage, by several of the San Francisco, Cal., physicians in cases of asthma, etc. An agreeable odor is disseminated through the apartment in this way.

Cerebro-Spinal Meningitis.—Dr. F. P. Whitehead, Vicksburg, Miss. (*Richmond and Louisville Medical Journal*, August, 1872), advocates the use of the fluid extract of gelseminum in this disease, and cites a case in which this remedy was very grateful to the patient.

Hæmatometra.—Dr. Wheeler, of Boston (*Journal of Gynæcological Society*, July, 1872), publishes two new cases of hæmatometra in the closed canal of a bicornite uterus with double vagina, observed in the Gynæcological Polyclinic of Dr. W. A. Freund, in Breslau. As regards the pathological anatomy, these cases presented but two peculiarities: first, the entire separation of the two uteri in the first case, a form not before observed in combination with hæmatometra. Even here the vaginal portion of the left uterus was so distended as to be nearly indistinguishable on the side of the tumor, and it was only after the operation that the true state of affairs, *i.e.*, the entire separation, could be made out. In the second case, where there was a real junction of the two cervices, the disappearance of the left vaginal portion was still more complete, and the os, existing as a depression on the side of the tumor, was the guide to the uterus. The second peculiarity was the smaller morphological condition of the tumors in the vagina, both being larger below and contracted above, like a ninepin or a partially filled bladder.

In these cases, the success of the treatment being complete, a long incision was made, and the completion of the discharge left entirely to nature; the patient keeping quietly in bed till the process was completed; and finally after the next menstruation, which in both cases followed immediately upon cessation of the abnormal discharge, a piece was excised in the first, and will be in the second, in order to insure a permanent outlet. Schroeder has reported 14 cases of the disease. Neugebaur, of Warschau, adds two cases of his own, and mentions six others reported since Schroeder. More recently still, Breisky, of Berne, has published two cases. In all these, with the two here reported, 26 cases. In 16 the diagnosis was correctly made. Operation was performed in various in 19, of which 7 ended fatally. Of the other seven, not operated cases, in one the tumor was accidentally opened through the uterine septum in an attempt to sound the healthy uterus; and patient recovered; one died at twenty-four, of heart disease; and two died as the result of the malformation. The complete reports of the other three cases are not accessible to the compiler.

Ligation of Carotid Artery.—Dr. Pigné-Dupuytren, San Francisco, Cal. (*Pacific Med. and Surg. Jour.*, Aug., 1872), at the June meeting of the San Francisco Medical Society, exhibited a patient, a cook by occupation, aged 44, in whom he had successfully ligated the right common carotid for aneurism, the size of the fist, on the right side of the neck, and extending from the clavicle to the lower maxilla. The ligature fell off the seventeenth day. On tying the ligature, the pulsation in the tumor at once ceased; in nine days it had returned slightly, and in three weeks it was marked; but meanwhile the tumor had considerably diminished in size. At the end of the second month the tumor was no larger than a nut, and in five months it had entirely disappeared.

Follicular Cyst.—Dr. Guersant (*Med. News and Library*, Sept., 1872), in the treatment of these, and all subcutaneous cysts, in children as in adults, is in favor of employing Vienna caustic. This method is much longer than when a cutting instrument is used; it may leave a more decided cicatrix, but it obviates mortal symptoms, and as a matter of good surgery, preference should be given it.

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, January 1, 1873.

THE SYSTEM OF SUBSTITUTION IN PRESCRIPTIONS.

THE communication from PROFESSOR BARKER, in another part of this journal, brings to the notice of our readers some very interesting, if not startling, facts bearing upon one of the phases of relationship existing between physicians and druggists. We would gladly suppose the cases to which he refers to be exceptional, did we hear of them for the first time. To many who have not been thrown into positions which compel them to be more or less at the mercy of unprincipled pharmacists, it will be difficult to comprehend the cause for such underhanded dealings. Even to such as are still compelled to write prescriptions, and who have not taken the pains to ascertain whether or not their patients get the proper medicines, the facts presented to them, while they will be no less surprising, will open their eyes to a fraud, the existence of which, from its very meanness, was unsuspected. We have objected to prescribing over the counter, of repeating prescriptions without authority, and of using inferior drugs; but we have been forced to acknowledge that such were mere accidents growing out of stubbornness and conceit, and what by a stretch of the imagination might be deemed, by the Knights of the Pestle, a practical illustration of what they pleased to call their individual rights. The substitution of one article for another in our prescriptions is probably an evidence on their part of another step in the same direction.

To these progressive gentlemen we would say, in the humble and becoming spirit of a profession always ready to learn, that we think it rather unkind that such a privilege should be denied us by our would-be teachers. We have acknowledged ourselves bad chirographers, admitting that we have a weakness for considering ourselves geniuses on that account; we are sometimes so far from being infallible that we make mistakes in our prescriptions, and not unfrequently are forced to excuse our shortcomings on the plea of ignorance, carelessness, and stupidity. But these conclusions have been forced upon us by the well-timed arguments of our friends the pharmacists. When we are overcome and driven to the wall, we have at least the satisfaction that we have been worsted in a fair stand-up fight; but in this matter of substitution we are rather ignominiously denied the usual privileges. If we ask for bread, and, naturally expecting to get it, receive only a stone, we have a right to ask the reason why. Herein is the great injustice done us.

There may be a good reason for asserting that the terminology of a word has no significance; there may be in the law of substitution a very acceptable and reasonable explanation why members of the same family may lose their individual identity for the good of one; why different things are similar; but why can we not know it, and, before knowing and admitting it, have an opportunity for a little reasoning in the premises? If we are really in the position of the philosopher with a large cat and a small cat, who cut a large hole and a small hole in his door for their respective accommodation, and our pharmacist would be willing to prove to us that the large hole would do for both, we can save ourselves much needless thinking. We refuse to be taught chirography; we feel too tender on that subject to admit the bland approaches of the blandest world-betterers; we are content to be joined to our idols, like Ephraim, and desire to be let alone; but when it comes to the interesting question of substitution and the apparently ingenuous laws which govern it, a new and inviting field is opened up to all who are unfortunate to be uninitiated. We shall not be unwilling listeners to the expounders of the new doctrine if we are given in turn the opportunity of upholding our side of the argument. But, if we object to the views advanced, we promise to do so on legitimate and rational grounds. If any one merely assures us that the sun is late in rising, because it is a few minutes behind the time marked by his watch, we may object to the premises, and may strive to prove that possibly the watch is a little slow.

The very fact, however, that we are denied the right of being convinced, may open the eyes of certain ill-feeling and cynical individuals to the suspicion that all is not as it should be, and some may be rash enough to assert that we are actually the victims of misplaced confidence.

THE HEALTH DEPARTMENT.

THE present State legislature will doubtless have no small amount of work to consider the usual number of bills which will be presented to them. Prominent among these, doubtless, will be the charter which the triumphant political party has spent so much time in framing. Where so much is promised

in the way of reform, the good citizens have a right to expect much. The interest which medical men will take in the proposed changes which this charter contemplates will be centred in the provisions for a new health law. This latter is certainly needed, and the reforms in this department should be as radical and as sweeping as in many of the others which have for the past few years formed a part of a notoriously inefficient and corrupt city government.

HUDSON COUNTY MEDICAL SOCIETY.

In many respects the District Medical Society of the County of Hudson, N. J., has adopted the commendable features of the Medical Society of the County of New York, in the various articles of the Constitution, but the following amendments would seem to be demanded:—In regard to the number of members constituting a quorum, five is too small a representation when important business is to be transacted, as injustice might unintentionally be done to absent members. One-fourth of the whole number would be better. The last paragraph of Article III., in reference to the investigation of breaches of medical ethics by the Comitia Minora, states that "the acceptance and adoption of every such report shall be decided by the Society without debate." The words *without debate* might, with propriety, be expunged.

The Table of Fees, revised and adopted in 1868, covering five pages of the pamphlet, however closely followed by members, will be found an encumbrance to the organization—judging from the experiences and histories of other medical societies.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, Oct. 23, 1872.

Dr. A. L. Loomis, President, in the Chair.

(*Continued from page 580, vol. vii.*)

Dr. Jacobi thought that the cyanosis was the result of the destruction of so much lung tissue by the emphysema.

Dr. Lewis Smith believed that it was well known that such apertures had nothing to do with the production of cyanosis.

Dr. Loomis remarked that it would be quite interesting to know the exact character of the murmurs, and their direction. There should have been a pulmonic murmur, and the question would arise if they were not all of that character. The only pulmonic murmurs he had seen, and which were confirmed by autopsy, were results of pressure upon the pulmonary artery.

HEPATIC ABSCESS.

Dr. Lewis Smith presented the anterior portion of the left lobe of the liver removed from the body of a boy who died October 15. Two years before his death, when in the country, he was severely injured by a fall, which fractured his left humerus and bruised his body. His convalescence was satisfactory, and he was apparently entirely well till the disease commenced of which he died. On Saturday, October 5, he played in the Central Park with other boys, and on the following day went to Sunday-school, appearing well and having his usual appetite. On Monday, October 7, he went to the public school, which he attended, and when there complained of headache, had epistaxis, and seemed feverish. He ate but little on returning from school, and was restless during the following night. On Tuesday, the 8th, the physician who had been summoned found him feverish and with pain in the head and epigastrium. The epigastrium was prominent, as if from an abscess or tumor underneath, and tender on pressure. There was no vomiting, and the bowels were opened by a purgative. At this time there was little or no meteorism, and the pain and tenderness were limited to the epigastrium.

From the 8th to the 13th, when I was called in consultation, there was no new symptom, but the patient had become progressively worse. The pain was more acute, and the tenderness had extended over the upper part of the abdomen. The features were pallid and expressive of suffering. The pulse was over one hundred and forty and feeble, bowels constipated, and this day, for the first, vomiting occurred. The upper part of the abdominal cavity was somewhat distended with flatus, and was the seat of severe pain, which elicited moans. The diagnosis of peritonitis was easy, which had evidently commenced in the upper part of the abdomen, and was rapidly approaching a fatal termination. Death occurred on the 15th.

Autopsy.—At the epigastrium the anterior part of the left lobe of the liver was attached to the abdominal parietes in front by recent adhesions, over a space perhaps of two inches in diameter. On separating the adhesions, about two ounces of thick pus escaped from an abscess in the liver at this point. The abdominal wall over the abscess seemed perfectly healthy, presenting no appearance of contusion; the surface of the left lobe was covered in its anterior part above and below by a thin and soft fibrinous exudation, which could also be traced a little distance upon the adjacent viscera. The liver, except in the immediate vicinity of the abscess, seemed healthy, as did also the vessels entering the liver; the other abdominal organs inspected *in situ* showed no evidence of disease; the walls of the abscess examined by the microscope were found to contain a large amount of connective tissue, the result of inflammatory action, numerous nuclei of this tissue and of the hepatic cells and hepatic cells undergoing disintegration; the surface of the abscess examined after the pus had escaped presented a grayish, uneven appearance, lacking the hyperæmia which is common in the walls of recent abscesses.

Remarks.—The cause of the abscess and its location are points of chief interest in the above case. Statistics show a great preponderance of cases of abscess in the right lobe of the liver over those in the left lobe, and when an abscess occurs in the left lobe we ordinarily also find one or more in the right lobe. The common cause of hepatic abscess in this climate is some inflammatory and ulcerative disease in one of the organs from which the portal vein arises. The hepatitis in these cases is embolismal, resulting from softened thrombi intercepted in the capillaries of the liver, and the abscesses are more frequently multiple than simple. In looking over the recent transactions of the London Path. Soc., for a period of five years, I find the histories of nine cases of hepatic abscess, having the following causes:—

	Cases.
Gastric ulcers	2
Ulceration in large intestines	3
Gangrenous ulceration of urethra and bladder	1
Ulceration in appendix vermiformis	1
Ulceration through cystic duct from gall-stones	1
Unknown	1

Suppurative hepatitis resulting from injury is known to be very rare, but in the case which I have related there can be little doubt that the abscess was traumatic, and hence its unusual location, which was in the exposed part. Lesions in the portal system, such as usually give rise to hepatic abscess, would hardly have escaped my notice if present; besides, there were no symptoms of such lesions. The boy, however, when questioned, could recollect no serious injury since the fall two years ago; but as he attended one of the public schools, where the plays are notoriously rough and exciting, it is not improbable that he may have received a blow in the epigastrium which he had forgotten. It is the opinion of the curators of Bellevue Hospital who have examined this specimen, and who see the lesions of this disease more frequently than any other physicians in this city, and probably country, that the abscess was not recent. They base this opinion on the amount of fibroid induration in the surrounding parenchyma and the little hyperæmia. It seems, therefore, that this abscess had been latent for an undetermined period, and that symptoms occurred when it approached the surface and gave rise to peritonitis.

I have been taught by this and other cases not to manipulate, or to manipulate very cautiously, suspected abscesses in the abdominal cavity, or deep in the walls of the thorax or abdomen, since their rupture internally is almost necessarily fatal, and they may in time, under proper sustaining and palliative measures, discharge externally or upon one of the mucous surfaces. The treatment in the above case consisted in leeching, moderate counter-irritation, poulticing, the use of opiates, and finally of sustaining measures.

The Society then went into executive session.

Stated Meeting, Nov. 13, 1872.

ABORTION—THE OLD STORY.

Dr. Finnell presented the uterus of a woman, aged 20, married two months, upon whom abortion had been produced. The operation was performed by some abortionist by means of some sharp instrument. The day following the patient was attacked with metro-peritonitis, and died in the course of the week. The abdominal cavity was filled with sero-purulent fluid. The cervical canal showed a deep ulceration from the instrument used in the operation.

RECURRENT FIBRO-CYSTIC TUMOR OF BREAST.

Dr. Benjamin Howard presented a tumor including the entire gland which he had removed from a female patient.

The patient was 42 years of age; had ceased menstruation; had two children, youngest being about four years of age. About two and a half years ago, a tumor which was considered a myxoma had been removed from the same side by Dr. Neftel, of this city. All was well until about eight months since, when a growth reappeared, which during the past two months had rapidly increased. He saw it. In consultation with Dr. Neftel, about two weeks since, I pronounced it fibro-cystic in character, and recommended its immediate removal. This diagnosis was qualified by a reservation concerning one point where hardness, pain, and adherence of the integument suggested a tendency to scirrhus. On removal, ten days since, aided by Drs. Neftel, Asche, etc., the tumor as now seen was found to present the appearance of an encysted fibro-sarcoma, the contents of the various cysts being either of a serous or colloid character. Although the tumor was quite an extensive one, the sutures were removed on the sixth day; the discharge was so slight, no cleansing of the wound was required, and the union by adhesion so complete, the dressings needed not to be repeated. The first tumor from this breast was reported upon, Dr. Howard thought, by the Microscopical Committee; that was the chief reason why he presented the present specimen; and having had no time for it himself, moved it be referred for examination to that committee. It was accordingly so referred.

MEDULLARY SARCOMA OF ANTRUM—OPERATION.

Dr. Sands exhibited a specimen of an amorphous-looking mass which he had removed by operation. The patient was sent him by Dr. H. Knapp, with the following history:—

Peter Heller, æt. 22, last May first noticed a pain in his left cheek, on account of which he had a tooth drawn, but was not relieved. At the same time the eye began to protrude: the left side of the nose became obstructed. The swelling of cheek, nose, and exophthalmus continued to increase gradually. The left eye is now four or five lines in front of the other. Mobility unchecked. Nothing abnormal in mouth. With difficulty forces air through his left nostril. Soft tumor of mucous appearance seen and felt in left nostril. RS=$\frac{20}{20}$, L=$\frac{10}{70}$ or $\frac{20}{100}$. Pupil moves readily. Shape, appearance, and tension of left globe normal. With the ophthalmoscope upper half of optic disk normal, the lower half raised and opaque (œdematous?) Close behind the infraorbital notch, hard, slightly nodular tumescence, extending from lachrymal region to bony edge of orbit, obliquely upward and backward, as far as the junction of outer and inner three-fourths of orbit. F. V. narrowed in its lower portion. Has circumorbital neuralgia at times, with pain on the left side of the face almost constantly since the tumor appeared. Lately, the nightly exacerbations have been severest at ten o'clock P.M.

Dr. Sands remarked that the patient had been treated by an eminent surgeon for what was supposed to be periostitis of the superior maxilla. On examination, however, Dr. S. was quite satisfied of the presence of a tumor in the antrum. The left nasal cavity was examined by the finger anteriorly, when a soft swelling was discovered, which was supposed to be, as it afterwards proved to be, the tumor itself. An examination posteriorly gave negative results. With the exception of the protrusion of the eyeball, there was little in the man's face to denote the presence of an extensive amount of disease; the anterior wall of the antrum was not much protruded, but the furrow corresponding to the anterior wall of the antrum was effaced. The history stated that the tumor had not encroached upon the mouth, and so at first thought Dr. S.; but a more careful examination revealed an important fact as regards diagnosis, viz., that the floor of the antrum was really deflected, projecting downwards into the cavity of the mouth. On examination of this protrusion into the mouth, an elastic sensation was discovered which helped to confirm the diagnosis.

The operation was performed on the afternoon of the presentation of the specimen. An incision was made extending from a little below the inner canthus along the furrow by the left side of the ala nasi, around the wing of the nose into the left nostril, then

as far as the median line, splitting the upper lip at that point. This was the only incision in the skin of the face. The anterior wall of the antrum was then exposed and removed without any difficulty, the section of the bone having been made through the pyriform aperture of the nose by means of a stout cutting forceps. This done, the tumor was easily examined. It was found to be very soft, and so friable that the finger could be run through it in every direction. The mass was removed partly by the fingers and partly by the scoop. The hemorrhage at one time was so copious as to oblige the operator for a time to desist.

To his disappointment, Dr. S. found that the tumor extended very far up towards the root of the nose. The superior and middle turbinated bones were broken down and removed piecemeal. After proceeding with the operation as far as the root of the nose both Dr. Knapp and Dr. Sands, appprehending that the cribriform plate of the ethmoid might be involved, thought that it was best to go no farther. The external and inferior walls of the antrum were found healthy. The last step of the operation consisted in the removal of the inferior turbinated bone *en masse*. Dr. E. Gruening reported the patient comfortable that evening.

Dr. Knapp remarked that while the upper part of the field of vision was normal, the lower part presented distinct signs of neuro-retinitis. The tumor itself was very large, but it did not appear to affect the infra-orbital artery or nerves. The operation did not seem to have interfered with them either. The growth increased so rapidly that a speedy operation was imperative. He had no idea that the tumor extended so far up, and would not be surprised to find that the frontal sinus was involved. It seemed to him to be a medullary sarcoma.

Dr. Sands remarked that immediately after the operation the eye resumed its natural position in the orbit.

INTRA-OCULAR ENCHONDROMA.

Dr. Knapp presented an intra-ocular tumor, the first on record. The operation for its removal was performed in Baltimore by Prof. Chisholm. The patient was a male aged 25. The enlargement first made its appearance at birth, when the sight was dimmed and a whitish appearance was noticed through the pupil. The tumor grew slowly but steadily, until the age at which it was removed. The deformity occasioned by its presence was very great, as was shown by photographic representations exhibited by Dr. Knapp. The operation was made in the presence of Prof. Gross, of Philadelphia, after the manner of enucleation of the globe. The fifth day after the operation hemorrhage occurred, which was stopped with some difficulty. On the ninth day there was another secondary hemorrhage of a more severe character. It so happened that it was impossible to control it during the whole night, and, the morning after, Dr. Chisholm was compelled to tie the common carotid, which stopped the bleeding. Three days after, the patient died of tetanic spasms. Dr. C. sent the specimens to Dr. Knapp, who reports the following results of a microscopical examination:—

The *tumor* consisted of three parts: 1, a fibrous enveloping capsule, from which septa run in different directions through the tumor; 2, a number of hard, round, or oblong nodes; and, 3, a softish fibro-granular substance lying on the lower side of the tumor, and extending between some of the harder nodes. Under the microscope, the enveloping capsule showed the structure of dense fibrous tissue like that of the sclerotic. The inner layers of the capsule were less dense, and interspersed with smaller and larger cells. The same structure, namely that of proliferating connective tissue, was seen in the fibrous septa of the tumor. The hard nodes consisted of fibrous and hyaline cartilage, the fibrous prevailing over the hyaline variety. The soft granular portion was made up of proliferating connective tissue, in which islets of fibrous and hyaline cartilage were embedded. Dr. Knapp entered into the details of the microscopic structure of the specimen, illustrating it with drawings on the blackboard, and demonstrating other drawings which he had previously made on paper.

With regard to the *origin* and *development* of the tumor, he thought it most likely that it sprang from the inner layers of the sclerotic. The fibrous cartilage was formed by immediate conversion of connective tissue; that of the hyaline cartilage by the growth of clusters of hyaline cartilage cells strown into the connective tissue and fibrous cartilage; furthermore by the extension of the growing hyaline substance into the fibrous cartilage, and lastly by the immediate development of aggregated formative cells into cartilage. The latter mode played the main part in the growth of the tumor. Dr. Knapp added that a detailed description of this unique case of intraocular enchondroma, with illustrations, would appear in the first number of the third volume of the *Archives of Ophthalmology and Otology*.

APOPLEXY WITH SOFTENING OF BRAIN.

Dr. Van Geison presented a brain, and read the following history of the case furnished him by the attending physician:—

"I was called, Oct. 31st, to see Alonzo Chandler, 23 years of age, and to all appearances a *most perfect* specimen of a strong muscular young man. Mother says he 'never had a doctor.' On this evening after a hard day's work at his trade (he was a shipjoiner), he ate a hearty supper and went with his mother to a festival at the church opposite my office. In going down the stone steps into the basement of the church, his foot slipped off the last step, and he came down hard, but on his feet. He went into the festival, conversed for a few minutes with his friends who were there, sat down at table, put his head on his hand, and was found to be unconscious. I was summoned, and arrived in a few minutes. Found him in profound coma and vomiting freely. Pupils contracted, not acting to light. He was carried home, and I followed. The right pupil remained contracted and left gradually dilated until death, which occurred at midnight, three hours from beginning of attack. Rigid muscular tetanic spasms, with gritting of teeth, and vomiting, occurred at intervals.

"*Post-mortem* held Nov. 1st, 10 A. M., ten hours after death.

"Questions asked his friends obtained information that for the past few months he had complained somewhat of 'dull headaches,' which he thought due to catarrh, but no notice was taken of the matter."

Dr. Van Geison remarked that he saw the man the next morning, and made a *post-mortem* examination. The heart was moderately hypertrophied, with the left ventricle very much thickened; there was a patch of atheroma in the aorta, and the valves, so far as could be judged, were tolerably healthy, and there were no traces of vegetations. Both of the kidneys were granular and beginning to contract. On removing the calvarium, the surface of the brain was perfectly healthy so far as one could judge from external appearances. On making an incision through the hemi-

sphere, a large clot was found, immediately surrounding which was a very large patch of cerebral softening, of a reddish yellow color. On examining the softened portion of brain there were no evidences of pus, although it seemed to the examiner that the process had been going on for a long time. The interest in the specimen centred in the latency of symptoms with such an amount of organic change present.

Dr. Delafield was of the opinion that the clot was the cause of the softening, an opinion in which Dr. Van Geison, from the appearances of the specimen when recent, could not concur.

SIMPLE DILATATION OF HEART FROM A STRAIN—A SINGULAR CASE.

Dr. Delafield next presented a heart taken from a patient of the Roosevelt Hospital, who had been a gardener by occupation. He was twenty-six years old, and had seemingly enjoyed perfect health, until two weeks before his admission, when, in attempting to lift a heavy wheelbarrow, he was seized with sudden dyspnœa, so sudden and excessive that he was compelled to drop the barrow on the spot and sit down. From that time his difficulty of breathing continued, and he was in consequence of it unable to lie down. He remained in that condition until his admission, Oct. 23. When admitted, his dyspnœa was so urgent that he was obliged to sit up in bed, his face was flushed, his eyeballs protruding, and his whole expression was very anxious.

On making a physical examination, there was found dulness over the lower lobes of both lungs; the voice sounds and respiratory murmurs diminished, although not entirely absent. On examining the heart, it was impossible to fix the apex beat. The action of the organ was tumultuous, its impulse being sufficient to move the chest wall considerably. The line of precordial dulness was four inches to the left of the median line and a little beyond the right border of the sternum. The liver was increased in size, the line of dulness reached to the fourth rib. The urine was scanty and high colored; there was, however, no albumen, no casts; and no œdema of the feet or legs. The patient remained in this condition for a few days, when the dyspnœa increased, and he grew rapidly worse, dying on the 3d of November—twenty-five days from the beginning of the attack.

The autopsy was made twelve hours after death. The brain presented no special lesion. Both pleural cavities contained a large amount of clear serum—on one side filling two-thirds, and on the other, one-half of the chest. The lungs did not seem much compressed. There were old adhesions over the upper lobe of the right lung, which was œdematous. Both lungs were dryer than usual. There was a moderate amount of muco-pus in the bronchial tubes, the mucous membrane of which was somewhat reddened. The liver was increased in size principally in the direction of its perpendicular diameter, and presented the ordinary appearance of such organs congested from heart disease. The abdominal cavity contained a considerable amount of clear serum. The spleen was enlarged and firm. The kidneys were also considerably increased in size, stony in hardness, and intensely congested. The microscopical examination of the liver and kidneys gave the ordinary appearances of these organs in a condition of chronic venous congestion. The same was the case with the kidneys.

When the chest was opened, the heart occupied a larger space than it usually does, and presented a peculiar globular appearance. The pericardium contained a moderate amount of serum, the sac being about a quarter full. The cavities of the heart contained a moderate amount of red clotted blood, except the right auricle, and were distended. Both ventricles and the right auricle were dilated. The walls were nearly normal in thickness, the wall of the left ventricle being $\frac{1}{10}$ of an inch, and the wall of the right ventricle a little over $\frac{1}{16}$ of an inch; the former being a little thicker, and the latter a little thinner than the average. The appearances of the heart wall were normal. A minute examination of the muscular tissue of the wall of the heart showed no change. The valves presented no change, except some slight thickening of the mitral, and a little atheroma at the base of the aortic valves, not however enough to impair their usefulness. No change in the aorta, except some few small patches of atheroma. The aortic valves were sufficient. The condition of the organs described left no doubt that there was a very intense and continued venous congestion, which must have been produced in some way by the heart, the heart itself showing no lesion but simple dilatation of its cavities. Dr. D., in conclusion, stated that he was unable to explain the condition of the heart with the apparent suddenness and persistence of the attack.

PHENOMENA ATTENDING SECTION OF THE RIGHT RESTIFORM BODY.

Dr. Mary C. Putnam presented a dog to the Society, with the following remarks: In the absence of one of the experiments prepared for us by nature, which we call disease, I would ask permission, Mr. President, to present to the Society a specimen of a rather curious disease, which has been the result of an experiment. The experiment in question was performed upon this dog, in my laboratory, though not by myself, on the 19th of last October, and consisted in a transverse section of the right restiform body. This operation, which is classical, was followed by the usual results. The pupil of the right eye immediately dilated, and this eye was drawn upwards and outwards; 1, irritation of inferior oblique, and passivity of superior oblique; 2, immediate loss of motor power of right posterior limb; 3, from section of lateral column that passes almost entirely into restiform body. Attempt to turn round from left to right only partially successful, owing to inability of dog to stand. But the head was strongly drawn towards right side, and the fore-paws went round in same direction.

As these rotatory movements are the well-known results of a well-known experiment, Dr. Putnam did not wish to insist upon them. There were, however, two points in this connection, to which, she said, I would call attention. At about the same time that this experiment was performed, I myself operated upon two rabbits, in one of whom I divided the middle peduncle of the cerebellum, in the other one of the corpora quadrigemina, in both cases on the right side. In the first case, the animal immediately executed movements of rotation around the longitudinal axis of its body, rolling over and over on the floor. In the second case, the animal leaped sideways, the entire body being translated to the right. Both these movements were notably different from those in the first case, where the animal described a circle, of which his own body was the radius, the posterior extremity being situated at the centre, the fore-paws placed on the circumference. In these two rabbits, moreover, the pupil, instead of being dilated, contracted.

The second point upon which I would insist, in regard to the dog, was that the muscles on the right side

of the body, from the neck backwards, were all contracted. In view of the many theories which exist to explain these rotatory movements, this fact is of interest; for it tends to justify the opinion which ascribes them to the predominance of muscular power on the side to which the animal is irresistibly forced to turn. This contraction was very much less marked in the rabbits. The subsequent history of the dog is more noteworthy, since it is rare that animals recover so completely as he has done from the operation. We had expected to find some hyperæsthesia of the opposite side on the following day, but no appreciable modification of the sensibility was discovered. On the third day the dog was partially recovered from the traumatism, and crept out of his box, but was still unable to stand. The head remained persistently drawn to the right. The dilatation of the pupil gradually subsided, and the eye resumed its normal position. By the 26th, seven days after the operation, the dog ran about freely, though dragging the right hind-leg, and with head as before. Seemed timorous and excitable, ran to hide his head against any person who spoke to him, as if afraid and trying to shelter himself. On this day was suddenly seized with a curious spasm. He stood still, a convulsive tremor ran down his right side, the muscles of which contracted spasmodically and with evident pain, for the animal began to run around frantically, always entering to the right, and then crouched in a corner, curling himself up so that the head touched the right hip, and remained crying for half an hour. He was not observed on the 27th, but on the 28th he had three similar, but much slighter attacks in the course of half an hour. The spasm occurred and lasted about a minute, after which the animal lay down as before, but without screaming, and the whole attack had passed off in about five minutes.

By the 30th the wound was nearly healed, and the motor power of the right hind leg was restored. The head did not resume its normal position until more than a fortnight after the operation. But before this time, the dog had already manifested the extraordinary vivacity which has since characterized him, and exaggerated moral sensibility. His mental and moral condition reminds the observer strongly of a patient in the initial stages of a diffused peri-encephalitis, and it is not impossible that ascending cerebral lesions may be in process of formation.

But the special point of interest in the dog's present condition, is an alteration of nutrition that has taken place in the skin corresponding to the lesion of the cord. On the 30th, when convalescence was fairly established, it was first noticed that the hair was falling off on the neck, and on the right side of the wound. In the course of a few days, a parallelogram was formed, extending from the original point, just behind the ear, down the neck, to the point of the shoulder. This zone was about two inches broad, and as the hair fell away, the skin was observed to be rough, thickened, and wrinkled. The alopecia has not been complete, and does not seem likely to become so.

This curious fact enters into a class of others, now becoming numerous, tending to prove, in the most direct manner, the influence of alterations of the nervous system upon the nutrition of tissues in their vicinity, even those that do not seem in close connection with them. In the Journal of Brown-Séquard, for ———, M. Charcot records some cases of eruption of bullæ, or the vesicular eruption of herpes zoster, consecutive to irritation of the radial * and sciatic nerves. In the *Archives de Physiologie* for 1868, the same writer enters more deeply into the subject, relates cases of profound lesions of the articulations occurring in the course of locomotor ataxy; and refers at the same time to cases of eschars occurring on the fourth day after traumatic myelitis; to others of localized œdema after apoplexy, etc. I have myself under observation such a case, where marked œdema of the arm followed hemiplegia. Parts showing this relation to the nutrition, especially of the hair, have, I believe, been recorded in the *Comptes-rendus* of the Société Biologie. But the most recent case in point, you will not forget, Mr. President, has been offered us by M. Brown-Séquard himself, when he did this Society the honor to exhibit before it some of his famous epileptic guinea-pigs. In one that had been rendered epileptic by section of the sciatic nerve, and was recovering spontaneously, M. Brown-Séquard showed that a fall of hair in the epileptogenic zone marked the entrance upon convalescence.* In this respect, therefore, this case of the dog resembles that of the guinea-pig. But in the latter case, the alopecia existed, not over the lesion, but over the point whose reflex activity had been excited by the lesion. In this dog, the alopecia was in the immediate vicinity of the lesion. But then the seat of irritation probably coincided with the seat of the lesion, instead of being remote from it, as in the case of section of the sciatic nerve.

Dr. Knapp expressed astonishment that section of the restiform body should have been followed by *dilatation* of the pupil. He had performed this experiment several times, and had always observed contraction. Pathological lesions of the spinal cord were, moreover, always accompanied by contracted pupil.

Dr. Putnam observed that there was a great difference between the results of a section and of a gradually forming sclerosis. In the latter case, the influence of the spinal cord was simply abolished, and the pupil left to the influence of the cerebrum, which always tends to contract the pupil. Whereas, immediately after section of the restiform body there is irritation, and consequent exaggeration of the functions of the spinal cord, which overpowers that of the brain. When the section is made higher up, as already noticed, the ascending irritation of the encephalon predominates over the descending irritation that might be communicated to the cord, and the pupil contracts. The same thing happens after section of the sympathetic in the neck, the instantaneous contractions being much more marked than that which afterwards exists as the consequence of paralysis of the nerve, and being really due to reflex irritation of the brain, propagated by the central end of the sympathetic.

Dr. Jacobi remarked that the case exhibited brought up the question of the influence of trophic nerves.†

* After compression of cutaneous fibres in a cicatrice, herpes zoster, as is well known, is now generally attributed to some lesion of the posterior roots.

* This observation is comparatively recent, for in 1868, in the *Archives de Physiologie* M. Brown-Séquard refers to the *anæsthesia* of this epileptogenic zone, but says nothing of the alopecia of convalescence.

† The existence of special nerves of nutrition, affirmed by Samuel, has been, as is known, much disputed of late. "Trophic centres," as in the ganglia for the posterior roots of spinal nerves, do not necessarily imply "trophic nerves." Because a tree must maintain its connection with the ground to live, it does not follow that this connection is maintained by anything but its own roots. Some of the facts above referred to, showing that lesions of ordinary spinal nerves produce decided alterations of nutrition, testify against the necessity for the intervention of special nerve fibres. Section of the restiform body would propagate descending irritation to the roots of the first and second cervical nerves, and the region of skin affected is especially supplied by their branches, the superficialis colli, and the acromial nerve.

EXTENSIVE ABSCESSES OF THE LIVER.

DR. ARNOLD presented a specimen of abscess of the liver with the following history:

Bridget McCoy, aged 45; widow; born in Ireland; occupation domestic. Admitted to the Bellevue Hospital Oct. 22d, 1872. On inquiring concerning history of parents, etc., found (parents) father died of asthma, mother died spitting blood, having suffered from dropsy just before death. Brother died of struma. Patient began to menstrate at 15 years of age; gave birth to 14 children. Never had a miscarriage. Was always a healthy woman up to last Easter, when her menses ceased. Since cessation of menses, she stated that she has suffered from indefinite ailments, frequently from headache, dizziness, and singing in the ears. Has had vomiting and diarrhœa; no swelling of the limbs or face. She further stated that for 3 months at least has had severe pain in the back, which would disappear and recur irregularly. Never noticed anything wrong with her urine. About 12 months ago, after a hard day's work, she felt very unwell, suffering from severe headache and pain in the back. Had no chills, but febrile sensation; vomiting came on and persisted. The next day she was attacked with diarrhœa, and this has continued ever since. On 18th Oct. (four days before admission into the hospital) she was seized with violent cough, and expectorated viscid, white matter, with severe pain on *right* side of the abdomen.

On admission, patient further stated that her habits have been temperate; since her menses ceased has had frequent attacks of epistaxis, and these still persist.

Oct. 25th. There is tenderness in epigastrium, all over *right* hypochondrium and upper part of right inguinal region. The superficial veins of abdomen are prominent. Oct. 26th. Complains yet of pain on right side; diarrhœa continues. A.M., pulse 104, respiration 28; temperature 101°. P.M., pulse 116, respiration 28; temperature 100½°. Oct. 27th. A.M., pulse 120, respiration 28, temperature 101°. Oct. 28th. A.M., pulse 112, respiration 28, temperature 100¾°. Diarrhœa still continues. Oct. 23d, urine, spec. grav. 1.012, acid albumen (trace). Oct. 28th, urine, spec. grav. 1012, acid albumen (trace). Oct. 29th, diarrhœa continues, physical examination shows bronchitis. Nov. 1st, A.M., pulse 132, respiration 48, temperature 98½; patient very weak. Physical examination shows presence of fine râles all over right side of chest behind, with dulness on percussion. Died at 4.05 P.M.

A second specimen also of extensive abscess of liver was presented, with the following history:

Henry Overton, æt. 32, born New York, admitted to Hospital Nov. 8th. Condition nearly pulseless. Complained only of pain in right hypochondrium. Died night of 8th.

In this case there was nothing particularly interesting connected with the autopsy, with the exception that there was some peritonitis. The abscess occupied the whole of the right lobe, extending into the left lobe.

DR. NOLAN exhibited a tumor from the anterior and upper part of the chest, which he had removed by operation from a woman aged 35. A previous operation had been performed eighteen months before; a tumor supposed to be cancerous having been removed from the same place, this growth returned in four or five months afterwards. At the first operation no skin was removed, but at the second operation all suspicious-looking integument was cut away. The mass, the size of a goose-egg, was composed of four smaller tumors, evidently malignant in character.

The Society then adjourned.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Adjourned Annual (sixty-seventh) Meeting; and Stated Meeting of Nov. 25th, 1872.

ADJOURNED MEETING.

DR. ABRAHAM JACOBI, PRESIDENT, in the Chair.

THE PRESIDENT, in resigning the Chair, said:

"The second term of my office has reached its normal end. I avail myself of this opportunity, while about vacating this chair in behalf of the President elect, to tender you my thanks for the honor twice conferred upon me, and to apologize for such shortcomings as are apt to be committed, in such a high office, by a man whose soul, it is true, may have been in the performance of his duty, but whose experience and knowledge, however, were certainly not in proportion to his good will. If there is any one whom I may have offended in performing the duties of my office, I ask his pardon; those, however, who have always looked upon my endeavors in behalf of this Society and the profession with favor or kindness will please accept my heartfelt thanks.

The last year has been, I believe, as successful as that which preceded it. The increase in our number has been steady, seventy-one members of the profession having been added to our list, while a number of names, part of them those of old and unusually valuable members, have been stricken from our rolls by death. The working of the committees has proved, on the whole, satisfactory, with the exception, perhaps, of one of them, in which a newly introduced feature—the subdivision into specialties—might have worked better. A number of reports expected by the society have not been forthcoming. As they were promised, however, we cannot say that the opinion of the Society, or of the members of the committee itself, was opposed to the change. On the contrary, further experience will have to show, whether the subdivision of the reports of the Committee on Intelligence will not prove as satisfactory to us as it is in accordance with the rapid progress of the several branches of medical science.

As far as the Committee on Meteorology is concerned, the Chair, last year, appointed its members to serve also on the Committee on Diseases. It may be that some further experience is still required to decide the question whether its abolition as an independent Committee is not a desideratum.

The following synopsis gives the most important features of the meetings held during the year past:—

December Meeting—Inaugural, and Paper on Foundling Asylums, by the President. *January Meeting*—Clinical Remarks on Diseases of the Conjunctiva and Cornea, by Dr. H. Althof. *Adjourned January Meeting*—Memorials of Drs. Bibbins, Geo. T. Elliot, A. N. Gunn, and H. D. Bulkley. *February Special Meeting*—To discuss and take action on the bill entitled, "An Act to protect the people against quackery and crime." *February Meeting*—Vital Signs in Disease, with special reference to Clinical Thermometry, by Dr. L. D. Bulkley. *March Meeting*—The Chemistry, Physiology, Therapeutics, and Toxicology of Veratrum Album and Viride, and their Alkaloids, by Dr. E. Peugnet. *April Meeting*—The Labyrinth of the Ear, Its Structure, Functions, and Diseases, by Dr. Knapp. *May Meeting*—The Physiology of Syphilitic Infection, as applied to the successive manifestations of the disease, by Dr. F. N. Otis. *June Meeting*—Resection of Maxillary Bones without Incision, by Dr. Goodwillie. *September Meeting*—Nomination of Officers, and Paper on the Neces-

sity of a Knowledge of Morbid Anatomy, illustrated by Cases, by Dr. E. G. Janeway.

The papers read before you were all very valuable. They did not all claim to have increased the stock of universal knowledge by the results of some original research, but by their own contents and the subsequent discussions they have added to *our* stock of knowledge. Real and rapid progress is the result of severe and solitary labor, such as can be performed, as a rule, only by those men whose sole or principal object in life is mental work. The scientific domain of medical societies like our own, is to foster and harbor scientific tendencies and ambition in the individual members, keep them informed, and give them an opportunity to express their own thinking on scientific facts or subjects, and by speaking improve their very thinking. Societies like ours form, as it were, the small *municipia* in the republic of science, consisting, perhaps, of not many citizens of egregious proportions or resplendent faculties, but of those who are sound, conscientious, thinking, progressive, and humane; seekers of truth, honesty, and the good of the profession and of mankind; proud of their position in the midst of anthropological science, and modest in the full knowledge that convictions are changeable, theories subvertible, and that seeking after truth is the only thing permanent.

Thus we ought to be proud to a higher degree of our facilities than of our faculties and accomplishments. Science is forever in its development, and even in its undeveloped state no single man has ever mastered it. This fact should be sufficient to extinguish vanity and self-complacency, qualities which are more common in an illiterate backwoods quack, or a gin-drinking sea-captain, than a humanitarian and physician, or a Laplace. Nor ought we, as physicians, to be so very proud of this our belonging to a profession, *the access to which is, I am sorry to say, as easy as it ought to be difficult.* What we accomplish in the profession in the interest of professional, scientific, and social progress, in the seeking for truth and its applications is the thing to be proud, although not to boast of.

What would you think of a physician who, on the standpoint of fifty years ago, would have boasted of his diagnostic accomplishments; auscultation and percussion in their cradles, and Bright's book not written? Or of a microscopist, who, twenty-five years ago, diagnosticated cancer by so-called cancer-cells, which we now know to have the only peculiarity of being impossible and non-existing? Or of a pathologist, who, twenty years ago, would explain cyanosis by a normal anatomical condition: the patency of the foramen ovale? As we would be unwilling to permit them to boast of their times, let us therefore be careful. We shall in our lives, I hope, throw off many an error, learn many a new fact and see light shed upon many a dark field. When we remember how we have outgrown our immediate predecessors in knowledge and, what is of more importance, in methods of investigation, let us be anxious not to deserve the smiles of the generation to come.

The meetings of the Society have been well attended. If any proof were necessary, the presence of one hundred and twenty members at the last election would be convincing. The same fact goes also to prove that the large majority of those in attendance were always members of the Society, not guests. The presence of the latter is surely pleasing, inasmuch as it exhibits, on their part, an interest in the persons of those who are expected to speak, or the topics to be discussed. As long as the legitimate objects of the Society are not interfered with, their visits are thankfully received. It is to be desired, however, that their interest in the person who is to be the lecturer of the evening should not be so powerfully superior to that in the subject discussed, that their presence should be thought necessary, even at the expense of private study and the requisite rest. I do not believe that the presence of hundreds of first or second course students of medicine or law aids the objects of a learned society, or their own studies, which might be more profitably given to the dissecting-room and to the notes taken in their didactic lectures. Nor do I think the members of the Society, provided they can find a seat on such occasions, are gratified by the noisy applause, on especially hitting or satisfactory occasions, equal to that in a concert-room or circus. We find that men with their hearts in a cause, and aiming at knowledge, will but rarely applaud. In fact, the opportunities for an outbreak so enthusiastic as to overcome decorum and the dignity of science, ought to be considered to be very few in number indeed. Nor, finally, can I imagine the members of a society to feel like entering a discussion when the final decision is, as it were, entrusted to the hands and feet of those who expect to come up in a year or two for their examination in the elements of medicine.

Moreover, a scientific society is a select circle of persons whose general education, in at least a number of subjects, must be considered equal or nearly so. Unless such is the case, a fertile discussion is out of the question. Nor is it impossible that many a gentleman, if he means to be intelligible to both guests and members, will avail himself of a phraseology accessible to every beginner; will avoid topics requiring more extensive preparatory studies; in fact, the character of discussions and papers *may* suffer. You say there is no necessity for that, and guests do not determine the character of the proceedings. Still, there is no man who is not influenced by large masses who have something intoxicating in themselves, and none who is superior to the wish to be understood by all who, for some reason or other, have come to hear him. While, then, it must be our object to be as numerous as we can —to count, in fact, all the members of the regular profession amongst our numbers—have as large meetings as possible—open our doors wide to every one who is competent, in the interest of ourselves and the scientific subject to be discussed, we should not encourage or crave the visits of guests whose very studies ought to confine them to other fields and narrower limits. Their interests and ours, for the time being, are not the same; if our proceedings are of such a character as to do justice to this Society and the standard of modern science, they cannot possibly gain by the presence of such persons in our circle, complimentary though it be. It is true, we cannot close our doors, nor say who is a desirable or undesirable guest; but the question once raised can be easily answered by any cool judgment. I do not hesitate to say that the meetings of a learned society are no place for a medical student, unless he be the exceptional one who, both by talent and work, is superior to hundreds of his fellows; as I have never hesitated, for a dozen years past, to advise the students of the first course not to visit any professor's clinique. If two do the same thing it is not the same. Where the necessary preparation is wanting, it is wasting time to battle with the higher branches. This may appear a delicate question. If I speak of the subject at all to-night, I hope it will be understood that I unwillingly submit to it as one of the stern duties of the office which has been intrusted to my hands for such a long time, and which I am about to deliver into those of a worthy and more competent successor.

The last year has seen no such disturbances as did a pre-

vious one. I co atulate the Society on this proof, or at least outward w, of decorum and professional propriety. No cha ges have been brought against any member, nor has any breach of professional ethics become public. No matter whether this is the result of nothing of the kind having occurred, or whether those offended or harmed have thought it below them to take notice of it, the result is a favorable one. Much valuable time has been saved, without the self-imposed discipline of the profession (which is the stricter, the looser the bands woven around us and our liberal profession by laws and statutes) having suffered in any way. We all remember to what extent, some time ago, our meetings, and a number of meetings of the comitia minora, were encroached upon by the pressure of individual claims, surely to the disadvantage of our legitimate duties. Many and various they are. I have in former times alluded to the many topics which might be subjects for discussions by this Society; and to the duties imposed upon us by our intimate connection with the political commonwealth. It is certainly our right and our duty to consider such matters as are of equal interest to both the citizens of the republic and to physicians. Amongst those I should count, first of all, matters belonging to the preservation and the restoration of health. Hygiene in general, the condition of the institutions of education, charities and correction, in particular, belong to this class.

This very Medical Society of the County of New York, and the Medical Society of the State of New York, are the legitimate authorities, without whom, as we now stand, no law, respecting in any way the public health, ought to be passed. Is the responsibility too great for us? Where is the responsibility to rest, except with those who have the required knowledge? Is it to be with the legislators, whose great merit consist in the fact that they had a majority of voters as ignorant as themselves? Or are we afraid of being accused of working in our own interest, when our discussions take hold of a subject of such vast importance to every living being; when, without remuneration and thanks, we improve the health of our neighbors, whose sickness would be of pecuniary advantage to us? Or are we to be afraid of being called the most terrible name on the tongue of a long maltreated and thoughtless public—a "ring"? As long as we work for the public good, whether we are five hundred or a thousand, we need not be afraid to be called a ring. And if we were five, instead of five hundred, this is the place in which the public interest, as far as health and life is concerned, ought to be considered and protected. In such questions of public safety, the County Medical Society ought to take a decided stand, and not fear the other terrible words, —*to commit themselves*. If there is a discrepancy of opinion, ours on one side, and the misinformed public on the other, it is much better to *commit* ourselves—that is, to pronounce our opinion, and conviction, and knowledge, without fear or hesitation. If Socrates, St. Paul, Luther, Galileo, and Giordano Bruno,—if Washington, and Paine, had feared to commit themselves, where should we be to-day? Fortunately for mankind, there have always been men and rings who have not hesitated to commit themselves in behalf of what they knew to be right, or in opposition to what they considered wrong; men, and sometimes rings, who would follow their convictions and consciences, no matter whether they expected to die with the crown of martyrdom, or that of glory on their temples. Nothing will change more easily than the vociferous applause or curse of the populace; no thanks will be more certain and perpetual than those of the genius of mankind for efforts and acts in the service of humanity.

I hope and trust that many questions of public interest will come before our forum, where they belong; that all questions of health and hygiene requiring investigation and discussion will be raised and answered here; that in true scientific ambition and co-operation, this Society will work with other equally interested societies and men; that, moreover, purely scientific subjects, that is, those whose immediate connection with the trivial bread-and-butter question of every day life is not yet found, will meet an ever-ready sympathy amongst us.

With these expectations and wishes for our welfare as a medical society, and as a professional, scientific, and public community, I retire from this chair, knowing that whatever one man can do in accomplishing tasks requiring honor, zeal, self-sacrifices, and capacity, will be done by my successor.

The minutes were then read and approved, and the meeting adjourned.

Stated Meeting.

The President elect, Dr. Ellsworth Eliot, took the Chair, and called the meeting to order.

NEW MEMBERS.

The following gentlemen, recommended by the Comitia Minora, were admitted to membership:—

Ira B. Reed, 154 East One Hundred and Twenty-eighth street; a graduate in medicine at the Bellevue Hospital Medical College, in 1868. George B. Fowler, 64 West Forty-sixth street; a graduate in medicine at the College of Physicians and Surgeons, in 1871. George V. Skiff, Metropolitan Hotel; a graduate in medicine at the Medical Department of the University of New York, in 1860. Montifiore J. Moses, 584 Seventh avenue; a graduate in medicine of the Medical Department of the University of New York, in 1863. Abraham A. Smith, 16 East Thirtieth street; a graduate in medicine at the Bellevue Hospital Medical College, in 1871. Jean B. Landetta, 275 West Twenty-second street; a graduate in medicine at the University of Paris, France, in 1863. Guiliermo Michelena, 78 East Seventh street; a graduate in medicine at the University of Paris, France, in 1847. Juan Cisneros, 473 West Twenty-second street; a graduate in medicine at the University of Havana, Cuba, in 1864. Walker Gill Wylie, Woman's Hospital; a graduate in medicine at the Bellevue Hospital Medical College, in 1871. L. Fiegenblatt (de Nasielski), 211 East Broadway; a graduate in medicine at the Medical Department of the University of the City of New York, in 1872.

MEMORIALS.

Drs. Krackowizer and W. T. White, as Chairmen of the Committees appointed for that purpose, presented the following memorials and resolutions, which were accepted by the Society:—

The Medical Society of the County of New York having learned of the demise of its member, Charles Henschel, M.D., cannot do less than bear witness to his love of science, his untiring industry, and his distinguished position as a practising physician.

By his whole life he taught the precious lesson, that sure success, not merely meaning the accumulation of wordly goods, but also the approbation and the respect of the good men of a community, is only for those

who lend their talents and attainments to the conscientious performance of self-imposed duty.

In this way Dr. H. succeeded in winning the esteem of his colleagues and the confidence of those committed to his care, to a degree shared by but few of the most eminent in the profession.

With a rigid adherence to, and advocacy of what he thought right and honorable, he coupled a rare affability, and a most liberal tolerance of the honest opinions of those from whom he differed.

He was singularly free from all guile and jealousy. It was his delight to seek out young men of talent, and by his advice and influence smooth their way to success.

As a citizen he was above reproach; he certainly loved his adopted, as well as his native country, and he identified himself fully with the destiny of the land of his choice.

Those who have had the good fortune to enjoy a more intimate intercourse with him as friends, will miss a gentleman of high culture, blended with a suavity of manner and an ease and instructiveness of conversation which made him the delight of social circles.

Bearing all this in mind, the Society, to show the sense of the loss it has suffered, attended the funeral of the deceased, and appointed the undersigned a Committee to prepare a suitable minute as an expression of their sincere sympathy with the family in their bereavement, and for preservation in the archives of the Society.

E. Krackowizer.
Ellsworth Eliot.
John T. Metcalfe.

New York, November 25, 1872.

Whereas, It has pleased an All-Wise Providence to remove by death our fellow-member, Gilbert T. Totten, M.D.; therefore,

Resolved, That in the death of our associate, we recognize the loss of one whose talents and scientific attainments rendered him an ornament to his profession.

Resolved, That we tender the family of the deceased our heartfelt sympathy in their bereavement.

Resolved, That these resolutions be transmitted to his family, and that they be published in the medical journals of this city.

W. T. White,
Committee.

(To be continued).

Correspondence.

THE ALTERATION OF OUR PRESCRIPTIONS BY DRUGGISTS.

To the Editor of the Medical Record.

Sir:—In a conversation a few weeks since with a medical student who had served two years as a clerk in one of our city drug-stores, he informed me that he was directed by the proprietor, when putting up expensive medicines, to put in only one-half the quantity ordered in the prescription. For example, if in a four-ounce mixture one drachm of quinine was ordered, he was to put in but half a drachm.

It is not to be supposed that this rule has been generally adopted by the druggists, but I have some reason for believing that the instance I have referred to is not entirely exceptional. Other information which I received from the same source has induced me to adopt the rule of thoroughly examining all powders and mixtures which are prepared from my prescriptions, and I carefully interrogate patients as to the action of pills, to ascertain whether this corresponds with the effects I anticipated from the ingredients ordered. The experience of a few weeks has convinced me that this course is not only wise but absolutely necessary. It has awakened my attention to the inquiry as to how much our success in treating disease, and, consequently, our reputation as practitioners, is in the hands of the druggist who puts up our prescriptions.

As an illustration of this point, permit me to mention a few incidents that have occurred in my practice within the past six weeks.

I was called about 3 A.M. this morning to see a little boy, five years of age, the only child of a widow, who is constantly on the watch for diphtheria. The child had a cold, with sore throat and some disturbance of the digestive organs, and I wrote the following prescription:—

℞ Potass. bicarb.,
"Tully's powder," āā..gr. x.
Hydrarg. chlor. mite..gr. iij.

M. Die in chart No. 2. S. One to be taken at once.

On visiting the child at ten this morning I found that he had not slept, was still feverish, and complaining of his throat. The anodyne effect which I had anticipated from his medicine had not been produced. This led me to examine the remaining powder, when I saw that there was no Tully's powder in it. Of course, the camphor in this would be unmistakable both to the smell and the taste. The powder is of a dingy white color, with an alkaline taste. I then rewrote the prescription and sent it to a trustworthy druggist. After taking one powder the child soon fell asleep, in a gentle perspiration; and on visiting him at five this afternoon, I found him asking for food, with no sore throat, and so well that I shall not again visit him unless I receive a new call. It was sufficiently vexatious to find that my night visit had been made entirely useless by the fault of the druggist, although the only harm done was the loss of time in relieving the child from suffering and the mother from anxiety. But suppose the case had been one of superficial inflammation of the larynx and trachea, or commencing catarrhal laryngitis, my prescription would have been very much the same, and it is my firm conviction that, in such a case, the loss of six hours' time might have resulted in converting a simple and easily-managed case into one of very great danger, viz., croup.

About three weeks since I was called to see a lady suffering from a severe form of ulcerative stomatitis. In the treatment of this affection, for a few years past, I have mainly relied upon the sulphites either of magnesia or of soda, and I have cured my cases more rapidly than I formerly did, when I depended upon the chlorate of potassa, borate of soda, etc. When writing for either of the sulphites, I have always written the word out in full, doubly underscoring the last syllable, so that the attention of the druggist should be called to the article required. In this case, I wrote a prescription for a mixture in which the sulphite of magnesia was the chief ingredient, and then assured the lady with a good deal of confidence that her mouth would be much better in a couple of days. Early on the second morning after my visit, I received a summons to visit her again, and found that she had not been able to eat or sleep since my former

visit, and that she now had a bad diarrhœa. I was much disappointed, and questioned her in regard to the medicine that she had been taking, and her answers convinced me that she had not been taking the sulphite of magnesia. Taking the phial of medicine, I called upon the druggist where it had been prepared. Being an entire stranger to the shop, I thought it safe to use a little diplomacy in getting at the truth. I first asked the "young gentleman" in charge to show me his sulphate of magnesia, which he readily did, informing me that it was the same as Epsom salts. I then asked if he had but one kind, and always put that up when ordered; both of which questions were answered satisfactorily. I then showed him the phial, asking if he was sure it was the same article which was put up in that. He looked at his prescription-book and then answered, with some temper in his tone, that it was, adding: "Do you think that we have put up oxalic acid? We never make such mistakes in this store." I then asked to see the prescription, to which he at first objected, but after a little persuasion he consented. I then asked the meaning of the two lines drawn under the last syllable of sulphite. He said: "Because it was spelled wrong. It should be a-t-e. But doctors were sometimes very careless in their spelling, and in my opinion some of them did not know any better." His last proposition I did not then feel inclined either to discuss or to dispute. But keeping a sober face, I gravely thanked him for his information, and left, satisfied—perfectly satisfied—that it was my duty to warn my patients not to have their prescriptions made up at this shop. I subsequently wrote a note to the proprietor of this store, detailing the above, to which note I have received no reply, and hence I suspect my conversation was with the proprietor.

In a third case, I had ordered for a child the subcarbonate of bismuth. At my next visit I was told that each powder seemed to distress the child, and caused severe vomiting. This led me to examine the powders, and not liking their appearance, I called upon the druggist who had put them up and asked him to show me the subcarbonate of bismuth. He took down a jar labelled Bism. Submit. On my remarking that this was the subnitrate, but I wished to see the subcarbonate, his answer was, "Oh, this is what we always put up now. The subcarbonate is an old-fashioned article that is out of date now, except with old fogies."

Now each of these incidents occurred at drug-stores of marked pretensions as to external display, situated in the best parts of the city, and which rely for their support on that class of society able to assist in paying their high rents.

I suspect that few of us reflect how much we and our patients are at the mercy of druggists. I have no doubt that most physicians, if they carefully watched, could furnish illustrations parallel with those that I have given.

The relation between the physician and druggist is one of mutual dependence. Both are liable to make mistakes, and no doubt the druggist frequently has occasion to protect the careless writer of prescriptions; but ignorance, inaccuracy, intentional omission, or unauthorized change of prescription, may be unpardonably criminal.

Our only safety is in sending our prescriptions to those druggists whom we have found to be thoroughly competent and trustworthy, and in a careful examination of the medicines after they have been prepared.

Yours truly,

FORDYCE BARKER.

MADISON AVENUE, Nov. 20, 1872.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from November 19 1872, to December 18, 1872, inclusive.

ALEXANDER, R. H., Surgeon, assigned to duty as Post Surgeon at Fort Vancouver, W. T., relieving Surgeon J. H. Bill, U. S. A. S. O. No. 154, Dept. of the Columbia, Nov. 14th, 1872.

RANDOLPH, JNO. F., Surgeon, assigned to duty as Post Surgeon at Omaha Barracks, Nebr. S. O. No. 204, Dept. of the Platte, Nov. 16th, 1872.

JAQUETT, G. P., Asst. Surgeon, granted leave of absence for 12 days. S. O. No. 208, Dept. of the Platte, Nov. 22d, 1872.

PHILLIPS, H. J., Asst. Surgeon, granted leave of absence for 30 days, and leave to go beyond the limits of this Department. S. O. No. 153, Dept. of the Columbia, Nov. 13th, 1872.

MEACHAM, F., Asst. Surgeon, assigned to duty as Post Surgeon at Sidney Barracks, Nebr. S. O. No. 204, C. S., Dept. of the Platte.

HEIZMANN, C. L. Asst. Surgeon, relieved from duty at Sidney Barracks, and assigned to duty at Omaha Barracks, Nebr. S. O. No. 204, C. S., Dept. of the Platte.

STYER, CHAS., Asst. Surgeon, granted leave of absence for four months from Dec. 1, 1872. S. O. No. 309, War Dept., A. G. O., Nov. 29th, 1872.

WEISEL, D., Asst. Surgeon, granted leave of absence for 30 days. S. O. No. 306, War Dept., A. G. O., Nov. 26th, 1872.

MATTHEWS, WASHINGTON., Asst. Surgeon, assigned to temporary duty at David's Island, N. Y. H. S. O. No. 228, Dept. of the East, Nov. 25th, 1872.

KING, W. H., Asst. Surgeon, leave of absence extended 30 days. S. O. No. 106, Mil. Division of the Mo., Nov. 21st, 1872.

MURRAY, ROBERT, Asst. Medical Purveyor, to proceed to Washington, D.C., and report to the Adjutant-General (pursuant to instructions from the Secretary of War). S. O. 222, Mil. Division of the Pacific, Nov. 30, 1872.

WIRTZ, H. R., Surgeon, to accompany Battery "B," 2d Arty., on 4th inst., to its station in the Dept. of the East, as medical officer, and on completion of this duty return to San Francisco, Cal. S. O. 223, Mil. Division of the Pacific, Dec. 2, 1872.

TILTON, H. R., Asst. Surgeon, assigned to duty as Post Surgeon at David's Island, N. Y. Harbor. S. O. 240, Dept. of the East, Dec. 16, 1872.

HUBBARD, V. B., Asst. Surgeon, assigned to duty at Jackson Barracks, New Orleans, La. S. O. 193, Dept. of the Gulf, Dec. 10, 1872.

VICKERY, R. S., Asst. Surgeon, to accompany batteries of 3d Arty., on steamer *Magnolia*, to New York city, and return by rail to New Orleans, La. S. O. 184, Dept. of the Gulf, Nov. 28, 1872.

MONROE, F. LE B., Asst. Surgeon, granted leave of absence for fifteen days, with permission to leave the limits of the Department. S. O. 265, Dept. of the South, Dec. 13, 1872.

CORSON, J. K., Asst. Surgeon, granted leave of absence for four months. S. O. 315, War Dept., A.G.O., Dec. 4, 1872.

DELANY, ALFRED, Asst. Surgeon, granted leave of absence for four months, with permission to apply for an extension of two months, to go beyond sea. S. O. 323, War Dept., A. G. O., Dec. 11, 1872.

MATTHEWS, W., Asst. Surgeon, when relieved at David's Island, N. Y. Harbor, to report in person at these Headqu'rs. S. O. 240, C. S., Dept. of the East.

REYNOLDS, FRANK, Asst. Surgeon, granted leave of absence for six months on surgeon's certificate of disability, with permission to go beyond sea. S. O. 323, C. S., War Dept.

JOHNSON, HENRY, Medical Storekeeper, to perform the duties of Medical Purveyor during absence of Lieut. Colonel Murray. S. O. 222, C. S., Mil. Division of the Pacific.

Medical Items and News.

BUTLER.—D. Butler, for thirty years Superintendent of the Insane Asylum at Hartford, Conn., has resigned his position.

NEW YORK ACADEMY OF MEDICINE.—At the meeting held December 5, 1872, Dr. D. B. St. John Roosa read a paper on "Chronic Non-Suppurative Inflammation of the Middle Ear."

BROOKLYN BOARD OF HEALTH.—Dr. Andrew Otterson has been appointed Health Officer of the Brooklyn Board of Health, in place of Dr. George Cochran, who died recently.

REYNOLDS.—Dr. Albert Reynolds, of Clinton, Iowa, has been appointed Medical Superintendent of the new Iowa Hospital for the Insane, located at Independence.

U. S. MEDICAL REPORT FOR 1871.—The United States Army monthly reports of sick and wounded, received during the year, represent an annual average mean strength of 24,101 white, and 2,494 colored soldiers. Among the white troops the total number of cases of all kinds reported on the sick list was 47,575; the total number of deaths reported was 367. Among the colored troops the total number of cases reported was 3,514; the number of deaths from all causes reported was 54.

DR. CHAS. HENSCHELL.—At a stated meeting of the New York Academy of Medicine, held Thursday, November 7th, 1872, the following resolutions were passed with reference to the decease of the late Dr. Charles Henschel, a fellow-member:

Resolved, That the Fellows of the New York Academy of Medicine recognize the hand of God in the death of their esteemed associate Fellow, Dr. Charles Henschel, which occurred in Zurich, Switzerland, on the 18th of September last.

Resolved, That as a tribute of respect to his memory, they wish to place upon record their appreciation of his long and faithful professional labors, as well as his kindness and cordiality, both as an associate and friend.

Resolved, That by the amiability of his private life and his untiring devotion to the care of the sick, he has endeared himself to a wide circle of devoted friends, and has left us an honorable example worthy to be cherished and imitated.

Resolved, That a copy of these resolutions, duly authenticated, be communicated to the family, and that they be published in the medical journals of this city.

E. R. PEASLEE, M.D.,
President.

W. T. WHITE, M.D.,
Secretary.

AT a meeting of the Medical Library and Journal Association of New York, it was unanimously

Resolved, That we have heard, with sincere sorrow, of the unexpected decease of our late trustee and associate, Dr. Charles Henschell. We tender our great sympathy to all the members of his bereaved family, in the sure trust that all the strong consolations which an all-kind Providence always showers around the memory of a good, kind, and wise man, will ever be present to comfort them.

Resolved, That we gladly hold up to our own members for their imitation the bright example of his truly honorable and unusually attractive character; his untiring devotion, both scientific and practical, to our noble profession; and his great skill and tender care of the sick.

Resolved, That we also gratefully acknowledge his interest in, and his generosity to, our Association.

Resolved, That a copy of these resolutions be conveyed to his family by a proper committee, and copies be sent to all the medical journals of this city.

A. UNDERHILL, M.D., *President.*
A. C. POST, M.D.
J. C. PETERS, M.D. } *Committee.*
F. A. BURRALL, M.D.

DEATH OF DR. WOHLFARTH.—AT a stated meeting of the New York Medico-legal Society, held on the 14th of November, 1872, the following preamble and resolutions were adopted:—

Whereas, This Society has authentic notice of the sudden and untimely decease of its esteemed member and officer, August Wohlfarth, M.D.:

Resolved, That this Society recognize in the death of Dr. Wohlfarth the loss of one of its earliest, and, though unassuming, one of its most zealous, faithful and efficient members and officers.

Resolved, That while this Society thus estimates its own loss, it extends its sympathy and condolence to the bereaved family of our lamented associate.

Resolved, That a copy of this expression of the Society be forwarded to the family of the deceased, and to the medical journals of this city.

T. C. FINNELL.
STEPHEN ROGERS, } *Committee.*
J. ROSS, *Recd. Secretary.*

NEW YORK MEDICAL LIBRARY AND JOURNAL ASSOCIATION.—At the annual meeting of this Association, held at the reading room, December 3, 1872, the following officers were elected for the ensuing year: *President*, Dr. J. C. Peters; *Vice-Presidents*, Drs. H. D. Noyes and A. Jacobi; *Recording Secretary*, Dr. F. A. Burrall; *Corresponding Secretary*, Dr. F. I. Foster; *Treasurer*, Dr. H. P. Farnham; *Librarian*, Dr. A. E. M. Purdy; *Trustees for three years*, Drs. A. C. Post, Wm. N. Blakeman, E. R. Peaslee, A. Underhill, H. G. Piffard, and Stephen Smith; *To fill vacancies*, Drs. I. E. Taylor and W. T. White.

DR. J. SOLIS COHEN, of Philadelphia, recently delivered, at the College of Physicians of Philadelphia, a course of ten lectures under the Mütter bequest, on the "Surgery of the Nares, Larynx, and Trachea."

POLITICS AND MEDICINE.—According to the Paris Correspondent of the *New York Daily Times*, evident radicalism prevails at the Paris School of Medicine among the students and professors, while anything like Communist language brings down the house. So well is the audience known, that professors are said to introduce politics designedly, and for the purpose of winning popularity.

Original Communications.

CLINICAL NOTES

ON THE

ELECTRIC CAUTERY IN UTERINE SURGERY.

By J. BYRNE, M.D.,

SURGEON-IN-CHIEF TO ST. MARY'S HOSPITAL FOR DISEASES OF WOMEN; CLINICAL PROFESSOR OF UTERINE SURGERY TO LONG ISLAND MEDICAL COLLEGE, ETC.

(*Conclusion.*)

As this paper has already far exceeded its proposed limits, and for other equally cogent reasons, my history of cases must close for the present. I have purposely endeavored to confine my remarks to a plain statement of such facts and occurrences as seemed to have a bearing on the value of the electric cautery in uterine surgery, including a description of the apparatus and instruments required, and rules for their practical application.

It is possible that the discursive manner in which my reports of cases and operations are given may be considered too inexact and disjointed; but I would state in explanation, that this paper is written less with a view to instruct students than for the information it may convey to active members of the profession; so that the dry daily record and minute details of cases, however useful and necessary to the one class, would be neither attractive nor profitable to the other.

Independently of this feature, however, I am fully aware that my clinical report, as a whole, is neither so full, nor by any means so complete, as could be wished; because, in addition to certain diseased conditions and operations therein described, and which in reality constitute but one-fourth of the whole number observed, there are many others of great practical interest that might also be related did time and other circumstances permit.

Prominent among the latter might be mentioned chronic catarrhal, inflammatory, and ulcerated states of the intra-cervical mucous membrane—as a class, the acknowledged opprobrium of gynæcological surgery, but yielding readily and in most instances to one application of the electric cautery.* Nor indeed does recourse to such radical measures for these obstinate ailments demand the use of any anæsthetic; for patients have repeatedly declared that no more suffering attends or follows such treatment than is observed when any other active topical application is made. So also in regard to inflamed and granular states of the urethral membrane, always a source of intense suffering to the patient, and, so far as my own experience goes, but rarely even alleviated by the most judicious methods of treatment ordinarily employed.

Yet these painful affections also, when not seriously complicated with vesical lesions, have, in several instances lately met with, disappeared no less rapidly by the same proceeding.†

I regret that, on these points, nothing beyond this mere reference to the facts can be ventured at the present time; but an early opportunity may be taken to submit some clinical illustrations of what may be reasonably hoped for in such cases.

With regard to the value of galvano-cautery as a means of excising epitheliomatous outgrowths from the uterus, I think sufficient clinical material has been presented to demonstrate, beyond all reasonable doubt, its great superiority over every other mode at our command.

My reports also indicate pretty conclusively the boldness and freedom with which we may, by this agent, safely encounter disease, however intimately connected with vital parts, the security it affords against hemorrhage, and, what appears to me of even more consequence, the very remarkable immunity it would seem almost to guarantee against peritonitis, cellulitis, pyæmia, and other fatal sequelæ of intra-pelvic operations otherwise effected.

As to the curability of cancroid diseases of the uterus by such radical measures as I have adopted and described, or the degree of permanency thereof reasonably to be hoped for, I have but little to add to the remarks already embodied in my reports. The statistics are, perhaps, as yet too limited, and, in most of my cases, the time that has elapsed since operative treatment is insufficient to warrant any very decided opinion one way or other.

It may not be presuming too much to say, however, that, judging from the apparently complete restoration to health in the great majority of patients so treated, though the condition of some was in the highest degree discouraging at the outset, I cannot hesitate to believe firmly that their ultimate history will warrant the most favorable conclusions in this regard. However, should future observation and more mature experience tend to dispel these hopes, and though cases now so full of promise should be found hereafter to have relapsed, it would nevertheless be some consolation to reflect that, in addition to having been instrumental in procuring respite from a painful malady, in no single instance had life been jeopardized by efforts made in behalf of these sufferers. Indeed, this latter remark is substantially applicable to some of the most hopeless forms of carcinoma when treated by galvano-cautery, as may be inferred from a perusal of case No. XII., and which is but one of several instances met with; for out of thirteen such cases operated upon, ten were beyond all doubt greatly relieved; and though three only were not improved, none were made worse.

The examples of carcinomatous disease of the uterus, either detailed or referred to in this paper, include nearly every variety described or met with, whether as regards their stage of development, the distinctive characters of their primary elements, or the tissues implicated. Hence it is needless to observe that, so far as the manifestly incurable cases were concerned, the parts involved or removed, the amount of relief afforded, and especially the extent to which life seemed thereby prolonged, varied in proportion to circumstances.

As to those of a less grave nature, they too, as may naturally be presumed, were of different forms and degrees of development, and consequently the steps and limits of operations proportionately varied.

Considering, therefore, all the facts observed in thirty operations, their subsequent progress, and inferences naturally deducible therefrom, the conclusion seems obvious that the electric cautery, when properly employed, is attended with less danger, immediate or remote, and promises better results than can be claimed

* In order to make such applications properly, the cervical cavity should be first well dried out by means of compressed sponge or cotton. The cervical cauterizer should then be introduced as far as may be judged proper, *and while cold*. The battery is next to be immersed, and during cauterization the instrument should be rolled half around and back, so that the parts may be equally and well brought under its influence.

† A similar proceeding to that advised for cauterization of the cervical canal should be adopted. The bladder must be completely emptied, and the urethra dried by cotton, before introducing the instrument. An anæsthetic is indispensable in these urethral cases.

for any other method of surgical treatment yet devised for such ailments.

It would be interesting, and perhaps profitable, to notice some important points touching the distinctive morbid features characteristic of each case or group; but having neither space nor desire to indulge in pathological hair-splitting or the discussion of questions irrelevant to the subject under consideration, what has been already said must suffice for the present, and may be accepted as a brief resumé of my opinions and convictions. Before disposing of this section of my paper, however, and in conformity with its aim and spirit, I would venture to submit, for the guidance of others, the following aphorisms pertinent to the operative management of this class of cases:—

1. In all cases of induration, destructive ulceration, and outgrowths of the cervix uteri of a malignant nature, or believed to be so, and therefore warranting excision by galvano-cautery or other means, such operations should never be limited to the apparent line of demarcation between sound and healthy tissue, but must include the whole vaginal cervix at least, and even more if need be. (See Case I.)

2. When the shape of a part to be excised is such that a loop cannot be made to embrace it, a circular furrow for the reception of the wire may first be made by the cautery knife.

3. The wire-loop, knife, or other instrument should never be brought to a white-heat when passing through superficial tissues or cellular growths. (See Cases XVI. and XVII.)

4. Traction on the part to be excised should be carefully avoided until the wire has passed well into the submucous structures.

5. The contraction of the loop should in all cases be very slow and gradual, *yet uninterrupted*, so as to insure a thorough cauterization of each stratum as passed through.

6. Towards the close of such operations, and as the circle of wire becomes small, let the amount of electricity be proportionately lessened.

7. Apply the knife to the spot intended to be cut *before heating*; and, if possible, be always provided with a duplicate of this little instrument.

8. Shun the use of persulphate of iron as a utero-vaginal styptic dressing, when possible, and, should any such agent be needed, substitute solutions of alum, or acetic acid, dilute or strong as circumstances may warrant.

The history of a very remarkable case of fibroid tumor has been described at such length, and the three operations undertaken for its removal in part so fully detailed, that but little need be said in addition to what is contained in the reports.

If, up to this time, proof has been wanting to convince the skeptical, and all who, on purely theoretical grounds, denounce certain forms of galvanic apparatus, because, as they say, their action is not sufficiently constant, these three operations amply furnish it. Others, too, who may have imagined, heretofore, that the galvanic cautery in surgical practice must necessarily be limited to small epitheliomatous or pedunculated tumors, fistulous openings, and birth-marks, will find for the first time how much wider its range of applicability may be extended.

That a highly vascular mass, fifteen inches in circumference, and situated within the pelvic cavity, has been successfully cut through and removed without loss of blood or subsequent inflammatory complications, is a circumstance in the history of galvano-cautery as suggestive as it is worthy of record.

The unfortunate occurrence that brought about a fatal issue in this case after the third operation, namely, exposure to cold, however deeply to be regretted, has nothing whatever to do with the merits of the operation, because up to the time of this accidental misfortune the patient was in a much better condition, and promised a more rapid recovery than at a like period after either of the two previous operations.

The report of an operation for the removal of an intra-uterine sessile fibroid (Case XIV.), exemplifies another and I believe a safer means than that of enucleation, by which the removal of these tumors may sometimes be effected.

Avulsion or enucleation of intra-uterine fibroids is admittedly a hazardous, and at best a most difficult undertaking, because, though encouraging results have occasionally attended the efforts of some surgeons in this direction, the operation is one from which those who are best qualified to appreciate its dangers and difficulties will be most apt to shrink.

I am not aware that any successful attempt has been heretofore made to sever the connection of such an intra-uterine growth as that described in my case, by means of the electric cautery; and though the proceedings therein adopted may be found impracticable in some instances, a persevering effort, when it is deemed possible, would, I think, in a conservative sense, be proper and advisable.

The interest that attaches to the case of fibrous polypus springing from the fundus uteri (Case XV.) is due more to the diagnostic lesson it conveys than to the means by which its removal was effected; because an error in diagnosis, regarding its real point of departure from the uterus, would in all probability have been fatal to the patient. When this tumor was exhibited at a meeting of the New York Obstetrical Society, two examples of this fatal error in cases precisely similar, were related,—one as having occurred in the clinic of Professor Scanzoni within the last two years, and the other in the practice of a prominent New York surgeon. In both cases the fundus uteri, being mistaken for the base of the pedicle, was extirpated, and the patients died in consequence.

Dr. Graily Hewitt,* referring to this subject, says: "When the polypus has a large basis of attachment, the fundus may be so drawn downwards that what appears to us the pedicle of the polypus is really the uterus itself. A specimen was not long ago exhibited at the Pathological Society, and referred to Dr. Marion Sims, Dr. John Ogle, and myself for examination, in which such a tumor had been excised, and a circular piece, comprising the fundus uteri, had been removed with it."

I have thought proper, also, to introduce another example of polypus (Case XVI.); the clinical features of which are no less peculiar and instructive than that last referred to. However, as certain inferences deducible from what was noticed in this case have been suggested elsewhere, and important principles, applicable to galvano-cautery, based on facts then observed, have been defined in aphorisms 3 and 4, no further remarks seem called for on the subject.

Case XVII. presents some interesting points for reflection, a few of which have already been glanced at in the report. I think this, as well as other similar cases met with, go far towards establishing a fact in the clinical history of such ailments, as well as certain principles applicable to their management, of great practical value.

Thus, however successful Dr. James Henry Bennet,

* Diseases of Women, first American from second London Edition, page 529.

and others who accept his pathology and therapeutics of inflammatory and congestive uterine diseases, may have been in "melting down" voluminous cervices by potassa cum calce and other corrosive substances, the most thorough, and by no means superficial, destruction of such parts by the electric cautery, and subsequent copious purulent discharges, cannot be relied on as a remedy for nutritive hypertrophy of the cervix uteri. Moreover, I feel justified in concluding, from my own observation, that amputation of the cervix by galvano-cautery, as compared with local depletion, caustics, and escharotics, offers the quickest, safest, most painless, and by far the most successful treatment for this very numerous class of cases. Whether the explanation already given in regard to the elevated position and immobility of the uterus noticed in this case, is the correct one, or likely to aid us in establishing some principle for our future guidance, will, of course, depend on further experience and the opinion of others.

This much, however, I may add: the circumstance, though probably noticed by others before, appeared so novel to me that I could not well avoid recording it, and the explanation and inferences are offered for what they may be deemed worth.*

In concluding this brief summary of my clinical experience in galvano-cautery I would simply remark that those who confine their appreciation of this invaluable agent in uterine surgery to its blood-saving properties, omit to take into consideration its most attractive and important attributes. These consist, first of all, in the peculiar manner in which this hæmostatic effect is produced on the vessels, and which I surmise is in no way analogous to that effected by ligature, torsion, ecrasement, or styptics. Secondly, as there are no disorganized blood-clots or other effete material to become absorbed into the circulation, blood-poisoning, as I have before observed, need not be apprehended as a sequel of cautery operations.

In other words, it would appear that not only are the blood-vessels securely sealed up, but the lymphatics as well, and hence the immunity from hæmatoxic and inflammatory complications.

NOTE.—In the first part of this paper I was induced to promise on behalf of instrument manufacturers, that certain defects in the construction of my speculum, of which I justly complained, would henceforward be remedied, and that the instrument would no longer continue to be made in defiance of every principle as explained in my original description of it. I regret to say now, however, that these promises and expectations have not been fulfilled. I have quite recently seen as worthless a specimen as it is possible to imagine exposed for sale in one establishment, and I am informed and believe that others equally useless are constantly being disposed of elsewhere.

Under these circumstances I cannot let this opportunity pass without warning the profession against the purchase of these imperfect instruments. *When the outside measurement of the anterior blade, transversely, exceeds one inch and a quarter, the speculum cannot be used without considerable pain to the patient, and, therefore, ought to be rejected.* As to those who have already purchased these instruments, their only remedy is to insist on being supplied with such as are perfect, both as to principle and workmanship.

314 Clinton street, Brooklyn, January, 1873.

DISLOCATED SHOULDER OF ONE HUNDRED AND THREE DAYS' STANDING REDUCED BY MANUAL POWER.

By B. F. SHERMAN, M.D.,

OGDENSBURG, N. Y.

On the 13th of August last, a lady called at my office, from whom I gleaned the following history. She was the wife of a farmer living thirty miles south of here; was *forty-five* years old, stout, and always healthy. On the 3d of May last she fell from the loft of the barn, and caught by the right hand, bringing the whole weight of the body upon the right arm. While hanging in that position she swung half round, and fell a few inches to the floor below.

On reaching the house, she was conscious of something wrong with the right shoulder. A physician was called, who pronounced the shoulder out of joint, and proceeded, with the assistance of the husband, to set it. After using a great amount of force, it was pronounced set and "all right;" but the patient had no use of the arm, and continued in pain. The physician called the second and third days; and on the fourth day a surgeon from a neighboring city was called in consultation, when it was again examined and pronounced "all right." At the end of two months (the patient having no use of the arm, and in constant pain) a third physician was called, who confirmed the previous diagnosis, that it was "all right." The daughter (an intelligent lady) confirmed this statement, and said her mother's shoulder looked then (the 13th of August) just as it did when she first saw it, the day after the accident. On examination, I found the head of the humerus in the axilla, and proposed to make the attempt to reduce it, although it was of *one hundred and three days' standing*. The patient assented to my proposition, but requested the presence of my brother, Dr. S. N. Sherman (to whom she had first applied, but whose health was too feeble to render any manual assistance). Calling in my brother, and my friend Dr. Z. B. Bridges, my diagnosis was confirmed, and proposition at reduction assented to by them. The patient was placed upon her back, on a broad, firm lounge of the height of a common chair; the half of a heavy, strong sheet was made fast by the clove-hitch to the right arm, just above the elbow, and the ends tied together, forming a loop. Chloroform was then administered until every muscle was relaxed. Passing the other half-sheet over my right shoulder and under the left, while seated in a chair by the side of the lounge, the ends were tied into the loop of the half on the patient's arm at such a length, that when my right heel was in the axilla I could bring into action all the muscles of the whole body except the left leg. When all was in readiness I took hold of the wrist with my right hand, and the arm, just above the elbow, with my left; my brother administering the chloroform and Dr. Bridges manipulating the head of the humerus with all his strength. I commenced a steady, firm, and powerful extension, at an angle of forty-five degrees with the body. At each increase of power the adhesions were felt to give till supposed to be sufficiently extended, when the arm was carried across the chest, making a fulcrum of my heel. This was repeated the second time without success, but the third trial was more fortunate,—the head slipped into the glenoid cavity, with no appreciable snap or jar, of course, as the cavity must have been well nigh filled up.

Suitable bandages were applied to keep the elbow close to the body, and to relieve the dragging weight upon the shoulder. After recovering from the chloroform (which she did very soon) she took a cup of tea, and 20 grs. of chloral (opium acting unkindly) gave her a good night's rest. Next morning she took the cars for home. Five weeks after, I saw her again; she was then able to move the arm in every direction, having little or no pain, and rapidly recovering the perfect use of it, though the deltoid was somewhat smaller than its fellow, from long disuse.

* There is a patient at present under treatment in St. Mary's Hospital for vesical and uterine prolapse, and whose future condition will serve to throw some light on these interesting points.

THE LARYNGOSCOPE AN AMERICAN INVENTION.

By G. TROUP MAXWELL, M.D.,

MIDDLETOWN, DELAWARE.

(Read before the Delaware State Medical Society, June 11, 1872, and published by request of the Society.)

MR. PRESIDENT AND GENTLEMEN: Your indulgence is asked, whilst, in this formal manner, I present for your consideration the grounds upon which I base my claims to whatever credit is due to the inventor of an instrument, which has signalized its efficiency by results so decided and brilliant as to have marked an epoch in the exploration of delicate and important organs, and the treatment of their diseases.

In this connection and at this point I may with propriety remark, that I do not undervalue the embarrassment arising from the disadvantage under which I must labor in an attempt to revive, or excite interest in, a subject which has been permitted to rest in abeyance for nearly twelve years; but I am sustained and flattered by the hope that I shall furnish reasons for this seeming neglect, which cannot fail to prove absolutely satisfactory and convincing to any unprejudiced mind. And I may properly remark, further, that whilst I shall aim and strive to put my own claims before the medical profession in as clear and strong a light as possible, I do not wish to seem even to desire to detract one iota from the applause so justly and so universally accorded to that renowned Hungarian whose name is indissolubly associated with the laryngoscope as its inventor. Indeed, I know that could a mean spirit of envy so possess and influence me as to engender a disposition to indulge in detraction, the noble instincts of a magnanimous profession would speedily administer condign rebuke. I would not, therefore, cast the slightest shadow upon his fair escutcheon if I could, and I am fully aware that I could not if I would. Indeed, I have not the purpose to institute a comparison even of our claims. Czermak's name, I repeat, must ever continue indissolubly connected with the laryngoscope, as its inventor. But whilst it is a living and abiding fact that to the distinguished Hungarian full credit is due, as against the world, for both originality of invention and priority of use of that invaluable instrument, I am here to prove, that close upon his heels, without one suggestion from any outside source, a humble American had worked out to a completely successful solution the self-same problem; and that, had Czermak never lived, or, living, had he never bestowed a thought upon the subject which his genius has so richly illuminated, the world would have had to wait but a few months for the priceless facilities for exploring and successfully treating the diseases of those delicate organs which the laryngoscope has furnished. I hope and expect to be able, by proofs which shall be forthcoming, to force the conviction on your minds that, almost at the same time that Czermak was conducting in Europe those experiments which culminated in his presenting to the world the perfect laryngoscope, I had, in the comparatively obscure capital of the State of Florida, invented a similar if not the same instrument, involving identical principles, and had, with eminent success, arrived at the same results.

If the data which I shall presently disclose to you are, as I think, sufficient to establish these statements as facts, then shall I expect to receive your endorsement of my claims.

Readily yielding to Czermak the palm for originality, and as against all competitors for *priority* in the successful employment of the laryngoscope, for the practical and useful purposes to which it is now daily applied, I shall urge my own claims to this extent only, that in utter ignorance of the labors of any one in this field of operation, and wholly independently of suggestions from any source, I designed and had an instrument made by Tiemann & Co., of New York, surgical instrument-makers, which was constructed upon principles so correct, and upon a pattern so well adapted to the purpose intended, that I had no difficulty in bringing into view the entire pharynx and larynx—I shall establish that my invention was a complete success and purely original, and that with the instrument of my invention I have seen the entire epiglottis, the glottis, vocal cords, and larynx in a living subject before any one on this continent—indeed, before any one in America knew of Czermak's experiments, and even before his successful results had been published in Europe.

In the fall of 1858 I left my home in Tallahassee, Florida, to visit New York, the medical metropolis, as it is the commercial emporium of the United States, for the twofold purpose of recreation and of studying the improvements and novelties in medicine which had been developed in the decade immediately following my graduation, then just closed. Desiring to devote special attention to the diseases of the respiratory organs, I naturally sought and made the acquaintance of Dr. Horace Green, who, beyond question, stood pre-eminent in that specialty in his day. To that distinguished gentleman I was placed under obligations, not only for the unusual facilities which his extensive practice afforded of seeing large numbers and an almost endless variety of cases, and the principles of treatment illustrated by his transcendent skill, but for marked courtesy of personal intercourse. Whilst visiting his office and watching the progress of cases under treatment, almost daily for several months, I was particularly struck with the frequency with which cases in which the organs of the pharynx and larynx, just out of sight, presented themselves. In such cases the utmost care was required in forming a diagnosis; and as deductions could only be formed inferentially from the signs and symptoms, and as the movements of the diseases towards a successful or unsuccessful result were also necessarily left to inference, the difficulties in the way of making a correct diagnosis, and of meeting changes in the cases with suitable modifications of treatment, were discouraging enough, to one of less skill and experience than Dr. Green. Impressed, then, with the great importance of removing that uncertainty of diagnosis and the embarrassment in treatment, I returned to my home and resumed practice, to very soon experience the magnitude of the difficulties.

Amongst the cases of interest which came under my care very soon after, was that of Mr. (now Col.) Geo. W. Scott, a native of Pennsylvania, then a resident of Tallahassee, and now a prominent merchant of Savannah, Ga. Having, as he supposed, either an inherited or an acquired tendency to phthisis, he had, several years before, sought the advantages of the genial climate of Florida, residing first in Quincy, and subsequently in Tallahassee. Although much improved in his general health by the change of climate, Col. Scott was the subject of an almost constant irritation of the throat, pharynx and larynx being both involved. In the beginning of 1859 he put himself under my care, and from the start I was oppressed by the difficulty of making an accurate or satisfactory diagnosis of his

disease, and of adopting a system of treatment which would satisfy my own mind. More and more the great advantage to be derived from *ocular* inspection of the diseased organs forced itself upon my consideration, until at last, during the latter part of the summer of that year, I had not only conceived the idea, but had devised the form, of a mirror to reflect those organs. My plan was to construct a mirror about an inch in length and three-fourths of an inch in width, elliptical in form, upon a suitable handle, which, being placed in proper position, would reflect perfectly the lower part of the pharynx and the upper portions of the larynx. Not being possessed of a large share of mechanical ingenuity, I was delayed some time in devising a handle that would give the desired angle, or one that would be adjustable; and the great distance from an instrument-maker rendered the idea of clearly defining objections to one which after it was made was found not to suit, and the difficulty of sending to and fro, absolutely impracticable. I therefore fell upon the idea of having my mirror to rest upon a short stem one-third of an inch long, terminating in a screw that would fit into the barrel upon the handle of Sims' uterine elevator. Feeling assured that the idea was practical, I then made a model of the mirror and forwarded it to Messrs. Tiemann & Co., directing one to be made, and telling them what I intended it for. In the early part of November, 1859, I received the instrument, and immediately applied it to investigating Col. Scott's case. In the first experiments I was embarrassed by the mist which condensed upon the face of the mirror, but that difficulty was removed by warming the mirror by holding it near the flame of a lamp. I was fortunate in commencing upon a subject whose throat was thoroughly educated to tolerate the contact of foreign substances by previous treatment with the probang; consequently I was spared the embarrassment, so often encountered by laryngoscopists, arising from so great sensitiveness of the fauces to the touch of instruments as to interdict the use of the laryngoscope, until the parts have been educated to toleration. Under the favorable circumstances described, I was not long waiting to see my fondest hopes crowned with complete success; for in my mirror were reflected perfectly the whole of the posterior face of the epiglottis, the glottis with the vocal cords, etc. It is but simple candor to confess, however, that I did not fully appreciate the importance and magnitude of my achievement until I read, the next year, the almost unbounded encomiums passed upon Czermak for the same results which had previously been accomplished by him.

I neglected to say, in the proper connection, that my mirror was made of steel, highly polished, and that I had one side made concave, hoping that it would in some way intensify the light and illuminate the dark passage. In this expectation I was of course disappointed.

My examinations of Col. Scott's throat were frequently repeated: I was thus assured in my diagnosis, and enabled to conduct the local treatment to a successful issue.

At that time and until July, 1860, I had never read nor heard of the experiments of any one in this direction, and, as I have already declared, I was not aided by the slightest hint or suggestion from any source. Living in a remote country village, without the advantage of public or large private libraries, I did not enjoy access to any writings which in any manner referred to the subject. I have since informed myself of the experiments of Liston, Garcia, and others who preceded Czermak; but at the time my experiments were conducted and my instruments perfected, I was totally ignorant of their experience. At that time Czermak's invention had not been made public in Europe even. His first public announcement was made in Paris in April, 1860, fully four months after my instrument was made. An account of his successful invention was not published in this country until July, 1860—then simultaneously in the *New Orleans Medical and Surgical Journal* and in the *American Medical Monthly*, New York, four months later. It will be seen, then, that it was impossible for me to have derived the slightest intimation of his movements from any source. And as "to Czermak is undoubtedly due," in the language of Prof. Gross, "the credit of being the first to employ such an instrument upon scientific principles, although a similar idea had occurred to Babington, Baumès, Liston, Garcia, and others," my purpose will have been achieved if I have shown satisfactorily and conclusively, as I think I have done, that my experiments were made wholly independently of his; indeed, that it was, in the nature of the case, impossible for me or any one else in this country to have known that he was engaged in experiments with the *laryngoscope*. This conclusion must be reached, when the fact is recalled that my instrument was made for me by Tiemann & Co. fully four months before any publication of Czermak's labors and their results was made in Europe, and not until four months later were the facts given to the public on this continent through our medical journals.

From these data it will be seen that my invention, although made subsequently to Czermak's, was as thoroughly original as his; and, further, that to me belongs the honor of having first, of all men on this continent, beheld reflected in a laryngoscope those delicate and important organs composing the pharynx and larynx—an honor vastly increased by the consideration that the instrument by which they were brought into view was of my own invention.

And now for the explanation of my long delay in bringing my claims before the public. My experiments, as I have shown, were begun in the summer of 1859, and were continued through the winter following. Besides the fact that I did not then appreciate the full value of my achievements, which encouraged a natural disposition to procrastinate, in the spring of 1860 I was honored by election to the Chair of Obstetrics, etc., in Oglethorpe Medical College, Savannah, Ga.; and beginning my preparations to move to that city, was engrossed in that business, and fitting myself for the arduous duties of the, to me, novel station, until the fall of 1860. Meanwhile my ardor in the matter was considerably cooled by the discovery that my invention had been anticipated by Czermak. Throughout the winter of 1860–61 my duties as teacher consumed my whole time, and the day that the college session terminated I gave up my profession and entered the army of the Southern Confederacy. There I continued until the conclusion of the war in 1865.

Upon resuming my professional functions, which had been suspended for four years, I discovered that amongst other losses I must count my little mirror, and, besides, all the correspondence and other data by which to establish the facts I have just been presenting to you. As soon as I had again begun to practise my profession I took steps to replace those evidences of my claims to being an inventor. I wrote repeatedly to Messrs. Tiemann & Co., and also, through the intervention of friends, sought to obtain from that house a transcript from their books of the dates and other items connected with the manufacture of the mirror. All my efforts were unavailing, however, until I made the acquaintance in March, 1872, of Dr. Bradford S. Thompson, of New York, who was then on a visit to Middletown.

in this State. Upon hearing the story of my disappointment his interest was enlisted in my behalf, and by the aid of his indomitable industry and persistence I was finally successful. As late as the 14th of last March Messrs. Tiemann & Co., instigated thereto by Dr. Thompson's interposition, wrote that they had not succeeded in finding any reference to the subject in their books; but in a letter of the 20th of March they stated that they had at last found the original entry, a copy of which they inclosed to me. That entry contains a charge against me "for one concave and plain steel mirror, made to fit Sims' uterine elevator," and is dated "October 26, 1859." By this evidence the date of the manufacture of my mirror is fixed beyond dispute, and this was procured after repeated efforts throughout seven years.

My purpose was immediately formed to bring the subject before the American Medical Association, at its session in Philadelphia in last May. I visited that city at that time, and obtained permission of the Association to present the matter to the Section on Surgery; but the Section was so overcrowded with business furnished by delegates that I could not obtain a hearing.

In conclusion, you will permit me to say that I hope I have succeeded in establishing all that I undertook to prove: 1st, My originality as an inventor; 2d, my priority in the successful employment of the laryngoscope on this continent; 3d, and finally, that I have used all possible diligence, though without success, to bring the subject before the public earlier. My delay has been the result of misfortune rather than of neglect. And now it only remains for me to thank you, gentlemen, for the patient and interested attention which you have given to me.

A CASE OF EXOPHTHALMUS, WITH MARKED DISTURBANCE OF THE RETINAL CIRCULATION.

By CHARLES S. BULL, M.D.,

ASSISTANT SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL, NEW YORK.

THE following case is of interest, from the fact that it was impossible to detect any cause for the affection, and that it remained uncomplicated throughout its entire course.

R. Q., aged 24, single, a native of Ireland, and by trade a watchmaker, presented himself at the Manhattan Eye and Ear Hospital on July 5th, 1872, with the following story: The patient stated that he had never had a sick day in his life, and had never had any venereal disease except an attack of gonorrhœa, several years since. About three months previous to his appearance at the hospital, he noticed that the left eye-ball commenced to protrude, and the prominence increased in degree steadily up to date of admission. The patient complained of no pain nor of any dimness of vision, and there were absolutely no subjective symptoms, except a feeling as if the eyes were steadily forcing their way out of the orbits. The objective symptoms were somewhat marked; the left eye-ball protruded very nearly half an inch beyond the superior orbital margin, in the horizontal plane, and did not vary a hair's-breadth from a line drawn perpendicular to the vertex of the cornea. There was a slight ptosis of the upper lid, the ocular conjunctiva was deeply injected, the vessels being larger towards the retro-tarsal fold, and on everting the lids the palpebral conjunctiva was found very much congested. There was profuse lachrymation on exposure to a bright light, but no photophobia. The cornea was perfectly normal, as was also the iris, and there was no ciliary injection. The pupil reacted promptly to the stimulus of light. Over the course of the external rectus muscle, from its insertion as far back into the orbit as it could be followed, ran a broad leash of large, tortuous vessels lying beneath the conjunctiva, but which could be moved over the muscle itself and which, on pressure being removed from them, filled again from the end towards the cornea. There was but little limitation of the excursive movements of the globe, and chiefly in rotation outwards. Vision was $\frac{20}{xx}$ for the distance, and the patient read Jaeger No. 1. with normal range of accommodation. Atropine was instilled, and on examination the media were found absolutely clear. There was a slight central physiological excavation of the optic disk, the refraction of the fundus being hypermetropic $\frac{1}{4}$. The outline of the papilla was somewhat indistinct, and there was very unusual development of the retinal and optic vessels. All the branches of the central artery and vein of the retina were very large and tortuous, and in the ascending and descending branches of the vein was the most marked pulsation I ever saw, which was propagated into the larger subdivisions, and in one ascending branch it could be followed almost to the equator. As the central artery bifurcated, the ascending branch passed over the ascending branch of the vein, and such a strong bounding movement was given to it by the pulsation of the subjacent vein, that for some moments I thought the artery itself pulsated. Beyond this, there was nothing abnormal to be seen in the fundus.

By pressing upon the eye-ball directly backward, it could be forced into the orbit, but occasioned great dizziness to the patient, and once a feeling of faintness. The heart was carefully examined and found perfectly normal. There was no irregularity of the pulse at the wrist, the number of beats in the minute being 82. There was no enlargement of the thyroid gland, and the patient was apparently in perfect health.

The patient was placed upon the use of potass. iodid., commencing with grs. x. *ter die*, and was directed to increase each dose by one grain every day, so as to make the daily increase three grains.

July 29th. Almost all the external conjunctival congestion has disappeared, and the eye-ball is a trifle less prominent, but the retinal vessels are still very much enlarged and tortuous, and the pulsation is as marked as ever. The *right* eye has commenced to protrude somewhat and the retinal vessels are here tortuous and swollen, and there is a venous pulsation in both branches of the central vein, though less marked than in the *left* eye. The potash was continued in grs. xxx. doses, and a leech was ordered to be applied to each temple.

August 5th. In the *left* eye the congested appearance of the papilla and choroid has diminished considerably, but there is still a slight venous pulsation in the main ascending branch of the retinal vein. In the right eye the congestion of the whole fundus is still very marked, but there is no venous pulsation visible. The potass. iodid. was continued, and the patient was advised to take two grains of the sulphate of quinine three times a day.

August 7th. In the *right* eye the injection of the ocular conjunctiva is still very marked, the eye-ball has become more prominent, and a pulsation is now visible in the descending branch of the central retinal vein. In the *left* eye the prominence is somewhat less, and though the veins are still very much engorged, the pulsation has disappeared.

August 12th. The injection of the ocular conjunctiva is still very marked in both eyes, the prominence of the globes is more evident, and the excursive movements inwards and outwards are more restricted. The condition of the fundus of the *right* eye remains about the same; but in the *left* eye the signs of congestion are very much increased, the ascending vein pulsating with great force, and in addition there is a very marked pulsation of the left external jugular vein, which had never been noticed before.

August 14th. The exophthalmus is still more prominent, but the conjunctival injection has diminished. The fundus remains the same.

August 23d. In the *left* eye the sub-conjunctival vessels, coming from the long posterior ciliary vessels, are very much enlarged and distorted over the course of the external rectus muscle. The condition of the fundus remains the same in both eyes as at last date.

August 30th. The prominence of the *right* eye is much less. The engorgement of the deep vessels over the external recti of both eyes is less marked. In fixation for the distance there is a perceptible divergence of the optic axes. The iodide of potassium was now discontinued, and tinct. digitalis, in doses of five minims three times daily, was administered. The venous pulsation in the *left* eye is confined to the ascending branch of the vein, but it is so marked as to be traced for a long distance beyond the border of the disk. There is still a venous pulsation in the *right* eye, but it is much less marked. It is thus seen that the condition of things has remained about the same since its commencement, with no improvement, and no materially unfavorable progress, and the cause remains still unknown to me.

No. 7 West Forty-sixth street.

REPORT OF EIGHTEEN OPERATIONS FOR LITHOMY, AND TWO CASES OF HERNIA.

By HENRY S. WEST, M.D.,

MISSIONARY PHYSICIAN AT SIVAS, TURKEY IN ASIA.

THESE have occurred since my communication in your journal of July 15, 1871, making the whole number reported one hundred and six.

Of these eighteen cases, ten patients were aged from three to ten, and the remaining eight, from twelve to twenty-eight.

Fourteen operations were lateral and four median. They were all cases of a single stone, but two, in one of which there were three stones, and in the other, two.

Eight stones were urates, four oxalic, seven phosphatic, one oxalolithic, and the other oxalo-phosphatic.

All but two weighed less than an ounce. Of these one weighed nine and a half drachms and the other forty-two.

All the patients recovered, or are recovering, but the case from whom this largest stone was taken. He was aged twenty-eight. For two or three years he had been mostly confined to the bed. Could not assume the erect posture, but stooped much when moving about the room. I was obliged to divide both the lateral lobes of the prostate and make a large external wound. Stone was removed without much delay. Patient bore the operation well, and for the first few days seemed in a fair way to recovery. No inflammatory or infiltrative symptoms. Afterwards he began to droop and the wound inclined to slough, involving also some hemorrhoidal tumors. He was removed from Sivas a week after the operation, in a feeble state, from which he did not recuperate.

Stone oxalic mostly, with two protuberances of evidently more recent deposits, apparently phosphatic.

Of the other cases I have nothing special to remark. One or two of those of longest standing suffered with symptoms of cystitis which yielded to the free use of morphine. The phosphatic concretions, some of them crushed under the forceps and could have been readily removed by lithotrity, if the patients had been of suitable age. Syringing thoroughly removed all débris.

Two cases of strangulated hernia I also report because they exemplify how the amount of intestine involved may modify the usual rule of prognosis founded upon the duration of strangulation.

The first case I saw August 6, 1871. The patient was a Turk, aged about twenty, who had been for several years the subject of a right inguinal hernia. Notes state:

"Nine days ago, in violent straining to lift suddenly a heavy load, the tumor was much increased, with all the symptoms of strangulation. Some days after, rude efforts were made at reduction and a pad and binder applied. There has been no fæcal evacuation since the accident. For several days stercoraceous vomiting. Abdomen quite tumid. Tumor very sensitive to the touch. Occasional paroxysms of severe colic. Pulse eighty (80), and full. Tumor of about the size of a pullet's egg, evidently entero-epiplocele. Made thorough efforts at reduction to no effect. Patient was unwilling to have me resort to the knife.

7th. This evening, again called, and after another effort at taxis, was requested to operate, which I was obliged to do by the flickering light of a pine torch. On opening the sac I found a mass of inflamed and adherent omentum, a considerable portion of which was nearly disorganized. This I dissected away, but did not attempt a complete dissection all around, which would have been tedious and useless. A small coil of intestine was thus completely surrounded, and the case, whatever it may have been at first, was now one of irreducible hernia. I divided the strictures freely, both aponeurotic fibres and the neck of the sac. Four arteries required ligature. Closed the wound with sutures, keeping a point at the lower end open with a tent. Patient comfortable. Pulse eighty and full. Gave calomel and morphia.

8th. No pain or vomiting. Takes milk and broth with relish. No relief of constipation. Gave an enema which was not retained. Afterwards gave castor oil, but it was vomited.

Evening. Pain in tumor and abdomen. Pulse one hundred. Gave calomel and morphia.

9th. Again pain and vomiting. Pulse one hundred. Continue calomel and morphia, and ordered another enema.

Evening. Enema brought some fæcal discharge. Vomiting ceased. Tongue clean. Some appetite. Pulse eighty-five (85). Still abdomen tumid and inguinal region sensitive. Dressed the wound, which looks well. Ordered cataplasms to the abdomen and tumor, to repeat the powders, and to take another enema.

10th. Enema not retained. Had not taken the powders. Return of pain and vomiting. Repeated enema, which brought a small amount of fæcal matter.

Evening. Much pain and jactitation. Strength failing. No appetite. Disposed to vomit. Pulse eighty-four (84). Repeated enema. Lotion of acetate of lead and opium to the wound.

Later. Enema had done no good. Patient takes no food. Pulse eighty-eight (88). To repeat the powder.

11th. Has had copious fæcal evacuations. Abdo-

men natural, soft. Pain and tenderness gone. Patient begging for food.

14th. Patient doing well. Pulse sixty-eight (68). Removed the sutures and considerable slough from the wound. Ordered frequent cleansing and detergent and antiseptic applications."

This patient recovered without further trouble.

I quote from the notes of the second:

"January 25, 1872, 8 A.M.—Called to see a Turk, aged forty-five, who has been for several years the subject of a left scrotal hernia. Has never worn a truss. Yesterday afternoon, while shovelling, felt something give way, as he expressed it, with an immediate enlargement and strangulation of the hernia.

Tumor very large, nearly obliterating the penis, and exceedingly hard, but percussion giving the tympanitic sound of a distended enterocele. Constipation, nausea, etc. Pulse rapid and feeble. Taxis produced no impression, save a little gurgling sound in the tumor.

Patient entreated for an operation, but he was evidently sinking. I gave morphia, which was not retained. He died at 9.30 A.M., within twenty hours of occurrence of strangulation."

The former case recovered after an operation on the tenth day, and an obstruction continuing fourteen.

The result of these cases was not what would be expected from the perusal of the statistical tables of Mr. Gray and others. The principal elements of difference seemed to be in the amount of intestine involved, and very likely the region also. No autopsies can be obtained in this country, so our pathology can only be read through symptoms.

Twelve years ago, an aged woman, on whom I operated for strangulated femoral hernia, on the sixth day recovered. A small portion of intestine was involved, but this was so nearly gangrenous that some days after the operation, some fæcal discharge commenced from the wound, which continued several days.

Sivas, August 27, 1872.

Progress of Medical Science.

Eucalyptus Globulus.—Dr. Wooster, M.D., of San Francisco, California (*Pacific Medical and Surgical Journal*), submits a report of 135 cases of various diseases treated exclusively with fluid extract of eucalyptus globulus. This preparation was made by Dr. Coleman, Resident Physician at the United States Marine Hospital.

Remittent fever: cases treated, 5; cured, 5. Intermittent fever, cases treated, 19; cured, 19. Typhoid fever: cases treated, 9; cured, 9. Nephritis: cases treated, 4; cured, 3; improved, 1. Duresis, cases treated, 10; cured, 7; improved, 3. Incontinence of urine: cases treated, 3; cured, 3. Vesical catarrh: cases treated, 27; cured, 25; improved, 2. Blennorrhagia: cases treated, 13; cured, 10; improved, 3. Valvular disease of heart: cases treated, 7; cured, 0; improved, 7. Dysentery: cases treated, 4; cured 3; improved, 1. Chronic diarrhœa: cases treated, 13; cured, 9; improved, 4. Gonorrhœa (syphilitic): cases treated, 15; cured, 10; improved, 5. Dropsy: cases treated, 6; cured, 3; improved, 3. Of the whole number of cases, 106 were cured and 29 improved.

At a recent meeting of the San Francisco Medical Society, Dr. Stout exhibited an ingenious apparatus for the inhalation of medicated vapors. The medicated liquid is kept boiling by a spirit-lamp and the vapor conducted through a tube. He had used the *eucalyptus* in this way, employing the tincture in water. It was preferable to the common atomizer, because of the warm vapor, which is not only medicinal in itself, but promotive of absorption. The eucalyptus he had found very beneficial in bronchial and pulmonic affections. Dr. Stout also distributed some cigarritos made by enclosing the powder of the leaves in a roll of paper, which were puffed by the members.

Dr. Pigné-Dupuytren testified to the virtues of the remedy, which had been fully tested by himself and Dr. D. Oliveira, in the French Hospital. It had been found highly serviceable in affections of the larynx and of mucous membrane in general; also as a tonic. In France it was much used as a febrifuge, and by some considered a substitute for cinchona. The leaves growing near the trunk of the tree were the most aromatic. A large number of the trees had been planted around the French Hospital, for sanitary and medicinal purposes. The leaves, in drying, emitted a large amount of balsamic exhalations, capable of causing headache in persons much exposed to them, as he had experienced in his own house.

Idiocy and Congenital Syphilis.—In a clinical lecture "On Inherited Syphilis," by John S. Parry, M.D., physician to the Philadelphia Hospital (*Philadelphia Medical Times*, September 2, 1872), the suspicion of a relation between idiocy and congenital syphilis is spoken of; that in a given number of syphilitic infants a larger proportion of them will be defective in mental development, than among the same number of children not so diseased. He would not be willing to express a positive opinion upon this subject without having had further opportunities to investigate it. He thinks, however, that the matter would repay examination. Two cases of idiocy combined with congenital syphilis, the patients being boys, aged six and a half and eight and a half years, were exhibited to the class.

Styptics.—In an inaugural essay, Dr. Charles H. Mitchell (*American Journal of Pharmacy*, June, 1872) presents the subjoined new formulæ: *Styptic Collodion.* R. Tannin, ℥ij.; Stronger Alcohol, f℥iv.; Stronger Ether, f℥xij.; Soluble Cotton, ʒj.; ℈ij.; Canada Balsam ʒj. Introduce the cotton into a suitable bottle, pour on it two fluid ounces of alcohol, shake well; then, add ten fluid ounces of the ether, agitate frequently until dissolved. Dissolve the tannic acid in a mixture of the remainder of the alcohol and ether, mix with the first liquid, add the balsam, allow to stand until clear: then pour off.

Collodion with Sesquichloride of Iron.—R. Sesquichloride of Iron, ʒj.; grs. 10; Stronger Alcohol, f℥10; Stronger Ether, f℥xij.; Soluble Cotton, ʒj.; grs. 10. Into a suitable bottle introduce the cotton, pour on two fluid ounces of the alcohol, and shake well then add the ether, and agitate frequently until dissolved. Dissolve the sesquichloride of iron in the balance of the alcohol, mix with the prepared collodion.

Eucalyptol.—According to the *Pacific Medical and Surgical Journal* for August, 1872, a volatile oil has been produced from the leaves of the eucalyptus, to which the name *Eucalyptol* is given. The vapor of eucalyptol, when breathed in a concentrated form, will produce symptoms of intoxication. In anæmic persons the oil produces sleep, in doses of fifteen to thirty grains.

Dactylitis Syphilitica.—John S. Parry, M.D., accoucheur to Philadelphia Hospital (Philadelphia *Medical*

Times, September 16, 1872), in a clinical lecture on "Inherited Syphilis," directed attention to the appearance of the fingers of a colored girl, aged eleven years, illustrating the uncommon lesion known as *dactylitis syphilitica*, which occurs in the later stages of both the inherited and the acquired disease. He remarked that the first description of this curious condition was written by Chassaignac, in 1859; but the most elaborate account of it was published by Dr. R. W. Taylor, of New York, in the *American Journal of Syphilography and Dermatology*, for June, 1871. Previously, only five cases of the disease had been fully described. To this number Dr. Taylor added two others. Since then, Dr. Smith, of Ohio, and Dr. Wigglesworth, of Boston, have each reported a case. Mr. Morgan, of Dublin, in his late work on "Practical Lessons in the Nature and Treatment of Contagious Diseases," describes the affection, and mentions having met with three cases of it.

Complete Compression in Aneurism.—R. J. Levis, M.D., Surgeon to the Pennsylvania Hospital (*Philadelphia Medical Times*, September 16, 1872), gives a report of the successful application of complete compression to a case of aneurism of the external iliac artery. Total arrest of circulation was effected, and continued during profound anæsthesia by ether, for five hours and a half. The instrument used was made by Mr. Gemrig, and consisted of a hollow pad for counter-pressure on the buttock, a rigid steel band for partially surrounding the pelvis, with a small convex pad and screw, adjustable in a slot in front of the encircling band. From consideration of this case, he offers the following propositions: 1st. That aneurism of the external iliac artery may be amenable to treatment by complete compression of the vessel in a brief period. 2d. That total arrest of pulsation can be effectually made by mechanical means. 3d. That compression of the external iliac at the cardiac extremity of the aneurism, probably even where aneurismal dilatation exists at the seat of pressure, and without the aid of aortic compression, may be sufficient for the cure. 4th. That anæsthesia is essential to such treatment, and that prolonged etherization does not prevent coagulation of the blood. 5th. That pulsation may not cease entirely for some days, even when a coagulum has been fully formed. 6th. That reduction in size of the aneurismal tumor, by shrinking of the clot, is more rapid and complete when cured by total compression than when the cure is effected by slow deposit of fibrinous lamina in the gradual or partial compression. 7th. That the treatment of aneurism of the external iliac by the method of complete compression is the safest and most reliable, and should be generally adopted.

A Local Anæsthetic.—J. Knox Hodge, M.D. (*Geo. Med. Companion*, August, 1872), recommends the following formula as a local agent of signal potency in all neuralgic affections, and for the relief of pain generally: ℞. Albumen of Egg, ʒj.; Rhigolene, ʒiv.; Oil of Peppermint, ʒij.; Collodion, Chloroform, āā ʒj. M. Agitate occasionally. Apply by smart friction with the hand, or gently with a camel's-hair pencil along the course of the nerve involved.

Cirrhosis and Albuminuria.—In a case of coexistence of albuminuria and cirrhosis, published in the *Chicago Medical Examiner*, of Oct. 1, '72, by Dr. N. G. Davis, the following prescriptions were directed, to counteract the increase of dropsical effusions by increasing the action of the skin and kidneys, and to sustain the strength and nutrition of the patient: ℞. Tinct. Digitalis, ʒij.; Fl. Ext. Lactuca. ʒij.; Syrup Prunus Virg., ʒij.; Iodid. Potass., ʒiij. M. Take one teaspoonful every six hours, ℞. Spts. Nit. Dulc. ʒiij.; Tinct. Ferri Chlorid., ʒj. M. Take one teaspoonful every six hours, alternating it with the other prescription.

Perinæorraphy.—W. Duncan, M.D., Savannah, Ga. (*Jour. Gynæcological Society*, Sept. 72), communicates a case of perinæorraphy with successful result, the patient being a colored woman, 28 years old, robust and healthy in appearance. The principal feature of interest in this case was the complete and perfect union of the parts throughout the whole extent of surface, vivified without any fistulous communication whatever, notwithstanding a persistent diarrhœa of several days' duration.

Living Cells.—S. H. Chapman, M.D., of New York (*Am. Jour. Med. Sciences*, Oct. 1872), remarks in his "Researches on Pericarditis," that it is the theory of Strieker and his pupils that all living cells are reliable, under the influence of inflammation, to divide and multiply into pus cells or embryonal cells; that these embryonal cells are capable of fully developed growth, forming anew all the elements of a tissue; but that, as in the production of species, only a small fraction of the embryos grows to full development, so here the great mass of embryonal cells is wasted as pus, while the small remnant alone attains a new and full growth.

Treatment of Asthma.—Edgar Holden, M.D., of Newark, N. J. (*Am. Jour. Med. Sciences*, Oct. 1872), records seven cases of asthma completely cured by the inhalation of the protoxide of nitrogen. The gas, fresh and pure, is passed through a jar containing a fluid extract of conium, Calabar bean, or belladonna, according to the necessities of the case, and from this jar is inhaled by the patient, once daily, before retiring, and for four or five consecutive days, the quantity varying according to the condition of the patient, but not exceeding five to eight gallons—never to anæsthesia—the sitting occupying at least ten minutes. Relief almost always follows the first inhalation, and, with one or two exceptions, thus far the first inhalation has produced an uninterrupted night's rest. Upon the disappearance of the nightly paroxysm and the subsidence of all oppression in breathing, the remedy may be discontinued; but must be instantly resorted to upon the first evidence of return.

Treatment of Intracranial Aneurisms.—Dr. Roberts Bartholow, of Cincinnati, Ohio (*Am. Jour. Med. Sciences*, Oct. 1872), remarks that the remedial management of intracranial aneurisms is not an entirely hopeless undertaking. Ligation of the internal carotid artery offers a reasonable expectation of success in the case of aneurism of that portion of the artery in the carotid canal. Ergotin, according to Hildebrandt, may cause absorption of uterine fibroids by its action on the vessels, and it is believed it may accomplish good results in intracranial aneurism. The solution employed by Langenbeck was as follows: ℞—Ergotini, gr. ij.; spts. vini rect., glycerini puræ, āā ʒss. Five minims contain ¼th of a grain. At the same time that ergotin is being used hypodermically, the iodide of potassium, in doses of from ℈j. to ℈ij. or more, three times a day, may be employed internally. Besides these two remedies, the galvanic current may be employed for the relief of the neuralgia of the fifth, which so frequently attends aneurism of the vessels at the base. A downward stable current, from six elements of Siemens and Halske, gave great relief.

In regard to his personal experiences, in the way of treatment, he says that in one case in which the character of the symptoms indicated an intracranial neo-

plasm, most probably aneurismal, he succeeded in procuring marked amelioration, and it may be cured by a persevering use of large doses of iodide of potassium, and the galvanic current. He has not reported this with the other cases, because there must ever remain a great degree of uncertainty in regard to the existence of an intracranial aneurism, the actuality of which has not been demonstrated by *post-mortem* examination.

Oxytoxic Action of Quinine.—R. H. Rutland, M.D, of Las Animas, Colorado (*Am. Jour. Med. Sciences*, Oct. 1872), has for eighteen years prescribed quinia in large doses, regardless of the pregnant condition of the patient, and has never seen any unfavorable result. Indeed, in treating a patient suffering from malarial fever, and threatened abortion, he esteems quinia the safest remedy for averting it; not because it possesses any special power to procure uterine quiescence, but because it would break up the morbid excitement upon which the uterine activity most probably depended. That quinia has no special oxytoxic properties in cases in which it is indicated, he is as well satisfied as of any therapeutic fact.

Cerebro-Spinal Meningitis.—R. I. Wilcox, M.D., of Algonac, Mich. (*Detroit Review of Medicine and Pharmacy*, Oct., '72), publishes five cases of cerebro-spinal meningitis, with complications. Judging from the congestive type the disease assumes, and from the intermittent character at the onset in many of the cases, and from the marked success of the treatment by calomel and quinine, he is induced to regard it as a disease dependent on malarious origin. The treatment having been adopted on the idea of the malarious origin of the fever, and proving quite efficacious, was followed out in all the cases with equal success.

The Electric Bath.—Alexander Murray, M.D. (*N. Y. Med. Journal*, Oct., '72), states from his experience and personal use of the electric bath during the last five years, he finds it a pleasant, invigorating, and useful adjunct in the treatment of diseases. He speaks with confidence and without speculation as to the beneficial effects in all forms of rheumatism and allied diseases, hysteria, chorea, paralysis, amenorrhœa, diseases of the bladder, cholera-morbus, cholera-infantum, and wasting diseases of children, etc. The length of time to remain in the bath should range from ten to twenty-five minutes. For children, five to ten minutes will be sufficient. (Children are so delighted with its pleasant, exhilarating sensations that it is difficult to get them to leave the bath.) The best time to take the bath is between breakfast and dinner, or a short time before retiring to bed. It may be taken at any time when a person may not feel in his usual health, or during the prevalence of an epidemic or any unusual electrical state of the atmosphere, but never when the stomach is full of food. There need be no apprehension of catching cold after taking the bath by going out directly in the cold air. In using the galvanic current, and to avoid giddiness and other unpleasant sensations, the positive pole should be placed at the feet, and the negative at the head. To apply electricity to a patient while in the bath, the quantity of the water in the bath-tub should be reduced, so that the upper surface of the body would be uncovered of water; then let the physician cover the body with a large towel well wet with the water of the bath, and commence the application of electricity at the head downward, over any part or parts of the body desired, by means of a large sponge-covered electrode connected with the positive pole of the battery. The patient should at the same time keep one or both feet pressed firmly against the metal plate at the foot of the tub.

Gastritis.—In a clinical lecture on "Gastritis" by Prof. N. S. Davis, of Chicago, Ill. (*Med. Examiner*, Sept. 15, '72), he says that one of the best items of nourishment is a mixture of three parts of sweet milk and one of lime-water. At first it should be given in doses of one or two table-spoonfuls, and repeated every hour. The lime-water neutralizes the excess of acid in the secretions of the stomach, and aid in preventing the coagulation of the casein of the milk until it is absorbed. Once or twice a day a small quantity of thin porridge, made of milk and wheat-flour, may be given in addition to the other. Also, occasionally a table-spoonful of animal broth may be allowed. For the first three or four days the following prescription is beneficial: R. Sub. nit. bismuth 40 grs., pulv. ipecac four grs., hydrarg. chlorid. mite, four grs., pulv. Doveri 20 grs. Mix, divide into eight powders, and take one before each meal-time and at bed-time. After three or four days the powder may be superseded by a pill containing one grain of extract of hyoscyamus and one-third of a grain of nitrate of silver. In some cases a pill composed of one grain each of extract of hyoscyamus and sulphate of iron, taken just before each meal, produces a very beneficial effect.

Operation for Coloring Corneal Opacities.—R. J. Levis, M.D., Surg. to Wills' Ophthalmic Hosp'l (*Phila. Med. Times*, Oct. 5, '72), after some experience, finds that the most convenient and effective instrument for coloring corneal opacities is made by binding together, with a thread, from three to six very fine sewing needles, for use in accordance with the size of the blemish to be removed. The points of the needles may be made to project equally by holding them perpendicularly on a hard surface before the binding is tightly applied. By inserting the little bundle of needles into a handle, as that of a cataract-needle, or into a hole drilled in the end of a stick of similar form, the instrument is rendered complete.

The great essential coloring-material is a deep-black tint, and this is perfectly effected by Indian ink, which is a combination of lamp-black and gelatin. For tinting in imitation of the iris, blue or brown pigments will be required, and other colors may be blended with artistic effect. To perform the operation, he does not ordinarily find it necessary with adults to use either the speculum or the fixing forceps. Operations on children or on restless adults may require the spring-speculum and fixation of the globe with forceps, and even anæsthesia might in some cases be necessary.

The Influence of Bromide of Ammonium on Quinia. H. C. Beall, M.D., of Coloma, Mo. (Kansas City *Med. Journal*, Aug., 1872), records his observations, with cases, on the corrective influence exerted by the bromide of ammonium on the action of quinia. By the use of the two agents in combination, he has succeeded in entirely preventing the cinchonism that usually follows the use of quinine in quantities sufficient to destroy the malarious influence; and, in cases wherein it did not succeed, its influence was clearly seen, the intensity of the cerebral excitement being sensibly diminished. He has also found that the bromide of ammonium exerts less influence on those cases that had repeatedly taken quinine in quantities sufficient to produce severe, and often repeated, cinchonism; yet even in such cases it has not proved entirely powerless. In no case has it apparently diminished the effect of the quinine; but, on the contrary, has seemed rather to serve as an auxiliary to its action, by holding in check the nervous system, equalizing the circulation, and thereby affording a more favorable condition of system for the action of the antiperiodic.

Intermediate Amputation.—Joseph W. Thompson, M.D., Paducah, Ky. (*Richmond and Louisville Medical Journal*, September, 1872), in cases of compound fracture of the lower extremities, does not believe, as a general thing, in amputations in the intermediate stage. When the time for primary amputation, which is established as decidedly the most favorable stage, has passed, he thinks surgeons had better trust the dangers that may arise in the intermediate condition, be they ever so grave, and await to take the chances of secondary amputation. He is satisfied that if accurate statistics on this point could be had, they would show a better success in taking the chances of the patient passing through the perils of the intermediate period, and then making a secondary operation. He publishes two interesting cases in connection with his remarks.

Chloroform in Eclampsia.—Benjamin Rhett, M.D., of Abbeville, S. C. (*Richmond and Louisville Medical Journal*, September, 1872), gives affirmative evidence of the value of the prolonged use of chloroform for allaying the irritability of the brain in cases of eclampsia; and does not hesitate to commend it to the attention of the profession, not as a curative, but controlling agent in this frightful malady.

Intermittent Fever and Paraplegia.—The *Madras Medical Journal*, of January, 1872, has an interesting Medico-Statistical Report to the Indian Medical Department, by Assistant-Surgeon G. Williamson, M.D., in which he dwells upon the cases of intermittent fever attended with paralysis and anæmia. The cases of paralysis, or rather paraplegia, coming on during the attack of fever, or succeeding it, were remarkable; and he has not noticed any mention of it in works on Tropical Diseases. Morehead mentions paraplegia coming on connected with cachectic conditions, but it is not stated what had induced the cachexia, whether malaria had anything to do with it or not. Some of the cases observed by Dr. Howell appear to have been of an inflammatory nature, as he sometimes uses the term myelitis; but the cases that came under his observation appeared more to be caused by dropsical effusion into the serous membrane surrounding the cord from weakened circulation; the complete absence of pain in loins or thighs, or derangement of the urinary organs or sphincters showed there was no inflammation. The cases were mostly protracted, and some required change of air, but they all eventually recovered, and were returned for duty.

Treatment of Cholera.—Assistant-Surgeon G. Williamson, M.D., 19th M. N. I. (*Madras Medical Journal*, January, 1872), in his treatment of epidemic cholera, while at Nunipilly, India, with his regiment, adopted stimulation internally by a mixture containing arrack, ammonia, æther, and decoct. chillies, Turpentine friction and application of warmth externally. For excessive vomiting, creosote, acetate of lead, and effervescing draughts containing hydrocyanic acid were given, and in some cases found useful. Arrow root conjee and broth were given at intervals, and cold water to relieve thirst. Five cases were treated with a mixture containing: Carbolic acid, ℥ iij. and Sulph. dil. ℥ xx.; Tinct. hyoscyam. ℥ xv.; Aquæ, ℥ ij. Two cases died, and the others recovered.

Experimental Researches on Pericarditis.—S. H. Chapman, M.D., of New York, records his observations on "Pericarditis," with twelve wood-cuts, in the October number of the *American Journal Medical Sciences*, as furnishing additional proof of the truth of the opinions held by Stricker in his controversy with Cohnheim. The specimens collected by him upon this subject during these studies were shown by Professor Stricker, in the course of his argument, for examination by the general assembly at Leipzig. The results of the investigations upon the inflamed pericardium are as follows: 1st.—All cell elements of a tissue during inflammation multiply. 2d.—New formation takes place, first, of cells; second, of connective tissue (false membranes); and, third, most probably of nerves.

Fatal Influence of Syphilis upon the Development of Scarlatina.—According to Dr. E. Woakes, cases of malignant scarlatina which are to be observed during those seasons when the character of this disease is commonly benign, derive their gravity from the fact that the subjects are tainted with hereditary syphilis. To illustrate this view of the subject he details five cases which occurred during an epidemic of scarlatina of nine months' duration, in all of which cases the subjects had this hereditary affection. According to him, this fact explains the well-known fact that in certain families scarlatina is almost always a fatal disease.—*Brit. Med. Jour.*, Aug. 24th.

Poisoning by Prussic Acid.—H. Wardner, M.D., Cairo, Ill. (*Chicago Medical Examiner*, October, 1872), mentions the case of a forsaken married lady, who swallowed an ounce vial full of prussic acid, and was restored by the following treatment: Ice-water was poured from a height of two or three feet upon her head during fifteen or twenty minutes; as this was done, her breathing became easier. The median vein of the left arm was freely opened, and the blood flowed in a small, slow stream, to the amount of four ounces. The head was then surrounded with ice, and hot mustard applications made to the feet and legs, while she inhaled the vapor of ammonia. During the flow of blood from the arm convulsions occurred, which lasted five minutes. The breathing then became natural. After an interval of ten minates there was a recurrence of convulsions, but less severe than the first, after which no more occurred. Two hours after his arrival she responded to the calling of her name, when he left her. The case was one of considerable anxiety to him, on account of the large quantity of the poison taken, and the result of the unusual treatment. A year after the first trial she was more successful in a second attempt "to shuffle off this mortal coil," which terminated her life and sorrows.

Evulsion of the Iris.—W. H. Folker, F. R. C. S., Surgeon to North Stafford-hire Infirmary (*British Medical Journal*, Oct. 5, 1872), relates a case of complete evulsion of the iris without other damage to the lens or sight, with perfect restoration to the eyeball. The patient, a railway pointsman, aged 42, was pulling at a piece of wood, when a portion of it suddenly broke off and flew up, striking him in the right eye with the splintered end. On examination, he found a wound in the outer and lower edge of the cornea. Atropine was at once applied, and antiphlogistic treatment employed. When all inflammation had subsided, and the corneal wound had healed, the iris was found to be completely torn away, a piece of the size of about two pins' heads only remaining at the corner of the wound. There was for a long time great intolerance of light, which, however, gradually subsided, and the patient at the date of writing was able to bear any moderate amount of light. The iris was perfectly clear. If anything the eye was slightly contracted.

Although there are on record cases of congenital absence of the iris, but such cases as the one recorded, he thinks, is sufficiently rare to justify him in thinking it worthy of publication.

Dengue Fever of India.—William W. Dunkley, L. R. C. P., Edin., Stoke-on-Trent (*British Medical*

Journal, Oct. 5, 1872), having been present in India during the recent epidemic, and having had cases of this disease under his care, gives a short, but interesting account of it. The term "dengue" is a corruption of the word "dandy." This disease was formerly known as the dandy fever by the natives of certain parts of the East Indies, because persons suffering from it assume a peculiar stiff gait when the subjects of the painful joints so common in the disease. The disease often begins suddenly, with little or no warning. The nature of the case is easily made out if the primary rash be present, which frequently happens within an hour or two of the commencement of the illness. It generally appears as an erythematous eruption of a bright-red color, sometimes only on the face, and sometimes almost or completely covering the body. It very much resembles the rash of scarlatina. It is not constant, and the fact of its being absent does not by any means prove that the case is not one of dengue. The pulse is often comparatively little higher than the normal standard, being often 95 or 98, and seldom rising much higher than 100.

In regard to treatment, after reading Dr. Charles' clinical lecture on dengue, he tried the tincture of belladonna, and it proved very useful, in doses of from eight to twelve minims. The pain was quickly relieved, and the patient had sleep. The remedy need not be continued long after the pain is relieved, and the patient's restlessness calmed. No other medicine is usually necessary, except perhaps a saline mixture, containing liq. ammon. acet. sp. ætheris nit., tinct. hyoscyami, and aqua camphor. The severe headache may be relieved by ice applied in a bladder to the head, and the strength should be kept up with nutritious soup or beef-tea, and milk, with occasionally a little brandy in it, etc. When the fever has abated and the terminal rash disappeared, a tonic is generally necessary, and a generous diet, with beer or wine, to bring up the patient's strength, which is often very much reduced. Patients often suffer from pains in the joints after an attack of dengue; but they usually pass off soon, and seldom require special treatment.

Chloroform in Labor.—Harvey L. Byrd, M.D., of Baltimore (*Physician and Surgeon*, Oct., 1872), gives the following observations concerning the use of chloroform in labor. It is of the greatest moment that the pulse and respiration be carefully watched from the commencement to the close of its administration, as much so, in fact, as in any other condition of the organism justifying or calling for its administration, if danger is to be avoided from its use. These functions afford the only accurate and sure indications of the propriety or impropriety, of continuing the inhalation. The administrator should stop immediately, if the pulse becomes weak, and the respiration difficult or irregular. Any hesitation or faltering in either should demand the instant cessation of the inhalation. Careful attention to these facts will enable physicians to keep the larger majority of women sufficiently under its influence, when desirable to do so, for hours; and thus through its agency, labor may, when necessary, be rendered absolutely painless.

Atropia Poisoning.—Thomas Opie, M.D. (*Physician and Surgeon*, Oct., 1872), by way of corroborating and giving prominence to the view that the physiological effects of opium are antagonistic to those of belladonna, reports a case of poisoning by atropia successfully treated by tincture of opium.

Aneurisms of Arteries at Base of Brain.—In an article on "Aneurisms of the Arteries at the Base of the Brain, their Symptomatology, Diagnosis, and Treatment," by Roberts Bartholow, M.D., of Cincinnati, Ohio (*Am. Jour. Med. Sciences*, Oct., 1872), based on the study of a case of aneurism of the basilar artery occurring in the practice of Dr. Isham, of Cincinnati; the letters of Lebert, containing 86 cases of intracranial aneurism collected from various sources; the monograph of Durand, embracing the statistics of Griesinger, of Lebert, and of Gougenheim, and cases published in various Journals and Society Transactions, the following statistics are given, grouping the arteries of the base into three systems: Internal carotid and its branches, the vertebro-basilar arteries, and the middle meningeal artery; cases of internal carotid (Lebert) 76, (Durand) 29, (the writer) 11. Of vertebro-basilar (Lebert) 35 cases (Durand) 11, (the writer) 7. Of middle meningeal (Durand) 3. According to Lebert and Durand, the individual arteries are effected in the following order: Basilar 36 times, middle cerebral, 34; internal carotid, 21; anterior cerebral, 13; posterior communicating, 8; vertebral, 5; posterior cerebral, 3; inferior cerebellar, 3; anterior communicating, 2. The 17 cases collected by himself make the following exhibit as regards individual arteries: middle cerebral, 7 times; basilar, 4; internal carotid, 2; vertebral, 2; anterior cerebral, 1; posterior cerebral, 1. With regard to the side of the brain on which aneurisms more frequently occur, the statistics of Lebert and Durand and those collected by himself do not agree. According to these authorities the difference in the two sides is as follows: Right side of the brain, 25 cases; left side of the brain, 35; occurring on both sides, 5. His own figures are as follows: Right side only, 6 times; left side only, 5; on both sides, 3. As regards sex, the proportion between male and female is nearly the same in his collection of cases as in the collections of Lebert and Durand. Of 114 cases given by these authorities, 61 were males and 42 females. The sexes in his cases were distributed thus: 10 males and 7 females.

Ectopia Cordis.—At the September meeting of the Suffolk District Medical Society, Dr. Fitz exhibited a fœtus which had been sent to him by Dr. Norris, of Cambridge. It presented an ectopia cordis; the heart was lying entirely outside the walls of the thorax, suspended in its place by the attachments of the large vessels. The pericardium was to be observed posteriorly, but not anteriorly. The child lived ten minutes after delivery, the pulsations of the displaced heart continuing that period. Besides this abnormality of the heart, there was a double harelip deformity.

Dr. Jackson remarked that specimens of ectopia cordis were preserved in the foreign pathological museums, but, so far as he knew, this was the first instance of the kind reported in that vicinity.—*Boston Medical and Surgical Journal*, October, 10, 1872.

The Fruits of Petroleum.—The subjoined commercial combustibles are made from crude petroleum:—

	Sp. Gravity.	Boiling-point.
Rhigolene	625	65° F.
Gasolene	665	120° F.
C. Naphtha	706	180° F.
B. Naphtha	724	220° F.
A. Naphtha	742	300° F.
Kerosene oil	804	350° F.
Mineral sperm oil	846	425° F.
Neutral lubricating oil,	883	575° F.
Paraffine	848	——

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M.,-M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, January 15, 1873.

A PROSPECTIVE HEALTH LAW.

THE promises of reform which the dominant political party have made since the election, naturally give more than usual interest to the announcement of the fact that the Legislature has commenced its session for 1873. As has been before intimated, the Committee of Seventy—the self-constituted custodians of the municipal interests, and the presumed controllers of political influence—have threatened our legislators with another charter. It will be recollected that last year the same committee carried out a similar threat, and, after a protracted and stubborn fight against what for the sake of their argument they called corruption, they were forced to yield to a defeat of their pet schemes of reform, and to sacrifice their opinions to the presumptuous wisdom of the majority.

It is to be hoped that the gentlemen who took such an active interest in the charter of the Committee of Seventy last year have been able to benefit by past experiences in legislation. They can certainly give no better evidence of a desire to meet the wishes and requirements of the community than to ignore the scheme of cumulative voting which formed the pivot upon which all their reform measures revolved, and which in itself was considered so defective by the highest legal authorities of the State.

But this is by the way. We leave all questions of the constitutionality of such measures with our law-makers and law-expounders, and confine ourselves to the consideration of such matters in a prospective charter as fall legitimately in our province as sanitarians. We are, as a profession, directly concerned in the framing of proper health laws. In view of the promises made of reform, and in view of the necessity of such reforms in our health department, the subject invests itself with more than ordinary interest at this time.

It is well known that the charter which brought the present Health Board into existence was framed more for the sake of perpetuating the political power of the Tammany Ring than for any other object. It was in fact so thoroughly political in its organization, that no one expected anything from it, and no one is now disappointed to find that it has failed to properly perform its legitimate duties. All the real work that has been accomplished has been by the executive officers and their assistants in the several bureaus.

The suggestions for reform are very naturally based upon acknowledged defects in the organization and working efficiency of the present board. To remedy some of these defects would not be difficult; and it is with such an end in view that we would offer some suggestions to our legislators.

In the first place, we contend that the Health Commission should be an independent department. This remark would seem on its face to be unnecessary, were it not the fact that last year the "Committee of Seventy" swallowed up all the distinct departments into what was styled a Department of Public Safety. This Department of Safety was to be under the charge of seven persons, and was to represent the Police, Health, and Fire Departments, and the Department of Public Buildings. We objected to this arrangement on many grounds, the principal one of which was that it would be impossible for any seven men to attend to more than one of these departments properly. And in regard to the Health Department, there was the very particular objection that no provision was made in the Board of Safety for the appointment of a single medical man. This and other arguments were urged against the practical workings of any properly organized Health Bureau, and we were pleased to learn that they not only commanded the serious attention of the legislators, but in the main agreed with the views expressed by eminent jurists in regard to other departments.

In the second place, a Health Commission should be composed of medical men, if not entirely, at least in a majority. The experiences of the present Health Board prove the opposite of this view in a striking manner. The medical element in this Board has been the merest cipher as to any influence which their opinions or counsels may have had upon their colleagues. At least their professional brethren have yet to hear of anything to the contrary of such an assertion. One of the reasons for this has been that there are but two Medical Commissioners, with the Health Officer of the port, against six laymen. This may also be the explanation why there has been, during the past year particularly, such stupid legislation in regard to sanitary matters, and such a disposition to work for political capital upon the slimmest possible show of benefiting the people. After all, of what good is a carefully considered professional opinion given by one or two medical men in a Board, when it

can so easily be cancelled by the votes of a majority of laymen! Until it can be proved that an educated medical men outside of his professional attainments has not the common sense and prudence which belong to any ordinary layman, we shall maintain that the medical profession have an unquestioned right to be fairly represented in every Health Board in the country. To add to the efficiency of a Health Board thus composed, it would be desirable to have a representation from the Police Department in the Board by one or two of the Police Commissioners. In respect to organization, the Metropolitan Health Board created in 1866 was a model of its sort, and its efficiency was acknowledged by every one who cared to spend the time for an impartial investigation.

In the third place, the appointments, at least as regards medical members of the Board, should not be political. The community have a right to expect that a man's scientific knowledge concerning sanitary matters should be measured by some other gauge than party claims. The profession have suffered not a little by such appointees claiming to represent them, and on more than one occasion have been forced to express themselves accordingly. The proper appointing power for a city naturally belongs to the Mayor, and his appointments of medical men for presumed medical attainments and special fitness for places of medical trust should be governed by parties who are the best judges of such attainments. In a word, the medical profession, through their societies or journals, should recommend or indorse suitable candidates. The history of our health appointments during the past few years has shown the very opposite to be the rule; the only guarantee for keeping a position being the ability to act as political weathercocks and party wire-pullers.

In regard to the necessary heads of bureaus, we may say a word. As they perform the really hard labor, their salaries should be in proportion—at least equalling those of the respective commissioners; and when the question of salary shall be taken into consideration, we hope to see ample pecuniary acknowledgment made for the over-worked, conscientious, and ever-ready Sanitary Inspector.

There are many other suggestions connected with the framing of suitable health laws which, not admitting of a general application, are deferred until there may be a possibility for their consideration in connection with some special provisions in the proposed new law.

THE NEXT PRESIDENT FOR THE STATE MEDICAL SOCIETY.

The question of the presidency of the Medical Society of the State of New York for the ensuing year is now beginning to claim the attention of the members of the organization. The position is one of such honor that no medical gentleman throughout the State is disposed to decline it. It has been always held by representative men, and there is no doubting the fact that the nominating committee will jealously guard the honor and dignity of the office.

The city of New York has been gratified in the choice of Dr. Agnew, the present president; and the next nominee should come from the rural districts. We expect to see Northern or Western New York represented at the next meeting, but should prefer the former, as it has not within our recollection furnished a presidential candidate. The presidency rightfully belongs to Northern New York; and the ambitious in other localities should courteously withold their claims in consideration of performing an act of tardy justice.

Reviews and Notices of Books.

Lessons in Physical Diagnosis. By Alfred L. Loomis, M.D., Prof. the Institutes and Practice of Medicine in the University of New York; Physician to Bellevue and Charity Hospitals, &c. Wm. Wood & Co. 1872. 8vo. Pp. 240.

The previous editions of this volume have been very well received, and, from their ready sale, appear to meet a well-recognized want.

There is palpable advantage in presenting the science and art of physical diagnosis by itself, apart from historical, pathological, and therapeutic considerations.

The great importance is felt by thus for the time making it the point of view in the study of disease: differential elements are illuminated by juxtaposition. Time is saved and slender libraries supplemented by gathering in one volume what must otherwise be sought in many.

Thus we find the plan of the work excellent, and, within the limits proposed by the author, very well carried out. It would be easy to point out many omissions; completeness and conciseness to a certain degree exclude each other; but in the space assumed it would be difficult to include a greater variety and amount of sound teaching. The style is compact, clear, positive and exact. It is free from all irrelevant discussions; nothing is allowed to disturb or confuse the distinct image of clinical facts. The teaching is of course, in the main, not new, and there is no reaching after novelty. But it has been very carefully collated. Little is given on the mere authority of others; contradictory statements are harmonized or otherwise disposed of by the judicial authority of the author as an expert; and we are persuaded that nothing is allowed to pass for doctrine which he is not fully prepared to defend from his personal researches.

The first half of the volume relates to the lungs and heart—with the other viscera of the thorax. Forty pages are given to the abdominal viscera; twenty to chemistry of the fluids; ten to microscopy; sixteen to the mechanical aids to diagnosis of respiratory and vascular disease; six to the ophthalmoscope, five to thermometry, &c., &c.

The mechanical execution of the book is very good in paper, type, &c.; but there is any quantity of bad spelling (presumably typographical errors), and occasionally an erroneous statement—some of them not so palpable as that which asserts that the ophthalmoscope mirror is *seventeen* inches in diameter!

The book is very creditable to its acute and indus-

trious author; and whoever shall practically master its contents cannot fail to be a discriminating and well furnished diagnostician.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, November 7, 1872.

DR. EDMUND R. PEASLEE, PRESIDENT, in the Chair.

DISCUSSION ON ACNE.

SUBJECT:—Discussion of Dr. Bulkley's paper on "Acne," and Report of Committee on Dr. Howard's paper.

The following new members were elected: Dr. T. Dwight Martin, of Morrisania, Westchester county, N. Y.; and Drs. Simeon N. Lee and Adoniram B. Judson, of New York city.

Appropriate resolutions with reference to the decease of the late Dr. Charles Henschel, drafted by Drs. Buck, Burrall, and the President, were submitted to the Academy, and passed.

The Committee to which was referred the paper of Dr. Benjamin Howard, entitled "The Preventable Deaths from Drowning within the Metropolitan District of New York," reported the following resolutions, which were adopted:—

Resolved, That the insufficient provisions made within the Metropolitan District of New York to save persons from drowning, call for some well-considered, vigorous, and immediate action on the part of the people.

Resolved, That this Academy will give such aid in exciting public attention and organizing public effort, as the importance of the subject invites and the functions of the Academy will allow.

The motion of Dr. A. C. Post, to continue the Committee, with power to devise some practical means in the future, for submission to the Academy, was passed.

DR. FANEUIL D. WEISSE, in opening the discussion, made the following remarks:—

Mr. President and Gentlemen:—I have listened with great pleasure to Dr. Bulkley's able and exhaustive paper upon this most unseemly and annoying, though not dangerous disease. It is an eruption for which, in its most frequent forms, such as the punctata, papulata, and indurata, the general practitioner does not as a rule undertake treatment, usually putting off the patient with the statement that "he or she will outgrow it;" if, however, importuned to treat it, he does so empirically, and with but little confidence as to a favorable result.

I must differ with Dr. Bulkley in the name which he has contributed to perpetuate. Acne, like eczema, is an unscientific term, which has been handed down to us from writers who had but little knowledge of the pathology of the diseases which they named. We find it first in the works of Aëtius, where, from an error of the copyist, the original Greek word *acme*, meaning *efflorescence*, was perverted into the present one of *acne*. I am in the habit of describing this eruption under the name of *Folliculitis seborica*, which I conceive to express the true nature of the affection. It is an inflammation of the walls of the follicle, induced primarily by an altered secretion, which, from its inspissated character, does not flow, but, accumulating, distends it. This pressure, together with the chemical changes of the secreted mass, irritates the wall of the follicle, inducing inflammatory processes therein, manifested by increased functional activity or secretion, producing the black specks of inspissated chemically altered sebum, plugging the follicle (punctata); areolæ of erythema and hypertrophy of the surrounding areolar tissue (papulata indurata). The folliculitis may result in exudation and suppuration within the follicle (pustulata). If a group of follicles is affected simultaneously, it produces the form known as rosacea. If we have a long-continued inflammation, with repeated exacerbations, the hypertrophic form is developed. The more frequent location of this eruption upon the face I conceive to be due to the free supply of blood to the skin of this region, and the ready arterial congestion, as manifested in the blushing from emotional impressions. With this condition of circulation it requires but a slight degree of tissue-irritation to produce an inflammation. I think that this view of the peculiar circulation of the skin of the face, as determining and prolonging its inflammation, is borne out by the fact of how long it takes for erythematous discolorations from other lesions to fade.

The period of life at which this eruption develops, is that wherein the hair is most active in its growth. We rarely see it before puberty, or after fifty years of age, unless at the latter period it should have been continued in a chronic form. As the sebaceous follicle is but an appendage of the hair follicle, and the sebum matures pomatum for the hair, the coincident activity in the development of hair and secretion of sebum is readily appreciated. From 15 to 25 is the period during which we find probably three-quarters of all cases of folliculitis seborœ, with its simpler lesions, viz., punctata, papulata, indurata, and pustulata. At this period the disease is more common in young men than in young women, because of the growth of the beard, after which growth affections of sebaceous follicles of the face are quite infrequent in men. From 25 to 40 years of age the complex lesion, rosacea, develops most commonly in women, and this, in its more chronic forms, may become hypertrophic.

As to the treatment of this eruption in its various forms, I resort to both external and internal measures; of the two, after correction of the digestive system, such as dyspepsia and constipation, I give decided preference to the external treatment. Of internal medicaments I have used arsenic, so as to effectually test its efficiency, inducing its toxic effects and sustaining the same from four to six weeks; and I am perfectly satisfied that it is inefficient in this class of dermatic lesions. From iron, particularly the iodide, I have had good results in scrofulo-anæmic patients. I can testify to the efficacy of Dr. Gubler's treatment with glycerine, and my own observations of affected patients is, that, with but few exceptions, they exclude fats of all kinds from their food. This observation I had made previous to seeing Gubler's experience, and, acting upon it, recommended my patients to take cream as an article of diet, from a half-pint to a pint a day, also almond and olive oils; and upon this theory I accounted for the successful use of cod-liver oil, as recommended by the French dermatologists particularly. Of topical measures, the first and most essential in my experience is the careful emptying of the follicles of their contents; this applies equally to all the lesions; it is effected by a fine cambric needle and well-directed pinching of the orifices. The second indication is to allay inflammation by means of hot water, rendered milky by kneading a bag of wheat bran in it. This is

to be used as a douche for ten or fifteen minutes at a time, repeated two or three times a day. Of medicinal applications I have tried about all that are recommended, and must give the preference to the non-irritating ones, with one reservation,—that chronic papular and tubercular lesions call for nitrate of silver, or even more powerful escharotics. About two years ago I commenced using the following preparations and local applications, viz., an ointment of sebum or suet carefully tried out, and scented with almond oil or some other perfume, and a compound powder consisting of equal parts of subnitrate of bismuth and creta preparata. These—the ointment and the powder—are to be used in the following manner: Before retiring, the patient is to use the hot bran douche, as above directed; after carefully drying, the ointment is then gently applied to the face, and allowed to remain on over night. In the morning the face is not to be washed, but the powder to be freely applied with a powder puff, and allowed to remain on ten or fifteen minutes, when it is to be brushed off (carrying the ointment with it) by a very small soft brush.

I do not wish to be understood as presenting this method of treatment as one to be resorted to empirically in all cases; nor do I intend to convey the idea that all cases are to be treated exactly alike, without taking into consideration diathesis, inherited or acquired, antecedent history, present hygienic conditions, and the possibility of external causes for the disease. When the case presents the more complex lesion of the rosacea form, I find excellent results in allaying the burning sensation and redness with this ointment: R. Sulphur, ℥ss.; pulv. camphoræ gr. v.; adeps, ℥j. M. Apply two or three times a day.

Hoping that others present may contribute their several experiences, I would again thank Dr. Bulkley for the pleasure and instruction his paper has afforded me.

Dr. John C. Peters said:—Mr. President, I will confine my remarks almost exclusively to the treatment of acne, with only such allusions to the pathology of it as may be necessary to elucidate the subject. Acne is universally admitted to be a disease of the sebaceous glands, sometimes of local and at other times of constitutional origin. It may easily arise from disease of the skin, for the soft cellular, or so-called Malpighian layer of the cuticle dips down along the hairs into the sebaceous glands, the cells of which are a modified continuation of those of the Malpighian layer, the modification consisting in the production of a great excess of fat molecules. As the sebaceous glands are also proper appendages of the hair follicles, acne may arise from abortive development of the hairs, irritating and disordering first the hair follicles, and from thence descending down into the sebaceous glands. Or it may commence in the epithelium, for these glands are lined throughout by a fine epithelium, the function of which is to change the albuminoid contents of the epidermic cells of the sebaceous glands into sebum or sebaceous fat. If this fatty metamorphosis does not take place, and the contents of the sebaceous glands become more albuminoid than fatty, then not only do the hairs and skin become less soft and flexible, but the one becomes hard and irritating and the other dry and cracked: for the normal unctuous secretion of the sebaceous glands should first anoint the hair-bulb, and then ooze out upon the stem of the hair and the neighboring surface of the cuticle. Hard, irritating, albuminous plugs may thus be formed in one or many sebaceous glands in place of the normal sebaceous matter, consisting of a mixture of olein, saponified fat, cholesterin, a small quantity of a peculiar unnamed albuminoid substance, and a few epidermic cells, the ashes of which should abound in earthy phosphates.

Again, these albuminous plugs not only act as mechanical irritants, but may, especially in scrofulous, lymphatic, or phthisical subjects, undergo cheesy degeneration, or further chemical change. We may infer what sometimes takes place in the walls of the sebaceous glands in acne, from what occurs on the skin in seborrhœa, for if the mass of sebum be allowed to remain it decomposes, then macerates and irritates the skin, producing redness, moisture, and inflammation of it. The same occurs on the glans penis, if the smegma or sebum be allowed to accumulate under the prepuce. The walls of the sebaceous glands become involved in the inflammation, which may extend to the connective tissue beyond, causing acne indurata, or even hypertrophica.

But acne is so often connected with gastric, intestinal, renal, uterine, and ovarian derangement, that it is probable that it often has a constitutional rather than a local origin; or, at the very least, these internal disorders will keep up and reproduce the acne again and again until they are properly treated and removed. If they do not cause the acne they prevent its cure, and insure its frequent relapse. We can get a little light upon this matter by a slight study of artificial acne, such as is often produced by the iodide and bromide of potash; these substances, as is well known, are absorbed, and may be detected in the urine; if they are not freely eliminated by way of the kidneys, they are carried in excess to the skin and there induce acne. Hence it is quite probable that in some dyspeptic, intestinal, renal, and uterine disorders, some changed or retained substance is carried to the skin, and there produces some form of skin disease, perhaps acne, or will so irritate and excite the skin that its previous diseases either remain incurable or become liable to relapse after relapse.

It is hardly necessary to discover new and wonderful remedies for the cure of acne, for it is very probable that we have all that is required except a more certain and accurate application of them. Among the most useful remedies is *acetate of potash*, when the urine is scanty and dark-colored; it is a mild but efficient diuretic in doses of 20 to 40 grains, and not only increases the quantity of urine, but also its solid constituents in a remarkable degree. It doubtless acts as a depurative and eliminative remedy. The sulphuret of potash—℥i. to Oi. of water—applied externally, twice a day, is recommended by Todd, who also gives it internally, as he thinks it peculiarly serviceable when dyspepsia is present, and the mucous follicles of the stomach are particularly implicated, and he thinks it exerts a specific action upon these gastric follicles. The *carbonate of potash* is an antacid, alterative and diuretic; in inflammatory acne ten or more grains may be given with 3 to 5 grains of *nitrate of potash* from 3 to 6 hours after each meal; aided by a lotion of ss. to Oi. of water.

The *borate of soda* is a refrigerant, diuretic, and emmenagogue, in doses of 5 to 30 grains. For external use, Copland prefers a solution of it in rose or elder-flower water to all other remedies; or in sulphur-water, made by pouring boiling water over flowers of sulphur and allowing it to infuse for 10 or 12 hours. Another good lotion is—Borax ℥i.; alcohol, ℥ss.; water, ℥iiiss.; or ℥ss. of borax to ℥viii. of water; or sodæ boracis ʒss. to aq. flor. aurant. and aq. rosæ each ℥ss. It is particularly useful in acne attended with amenorrhœa, or with ulceration of the os, or other uterine disease. When constipation is also present, 3 or 4

grains may be made up into a pill, with 1 grain of aloes. This combination is particularly useful in amenorrhœa with constipation.

The *muriate of ammonia* is an allied remedy, strongly recommended by Jurdelin as an emmenagogue, and having alterative and resolvent properties closely resembling those of mercury. It is peculiarly useful when there is amenorrhœa and bilious derangement. It may be given in 5 or 10 grain doses, in water, three times a day; or made up into a pill with aloes. It should also be used as a lotion.

Sulphur also promotes the menstrual discharge, and relieves congestion of the liver and whole portal circulation, while Jurdelin thinks that it acts specifically on the mucous membrane of the intestines. Some of it is converted into a sulphide by the action of the alkali of the bile, and is enabled to enter the blood, whence it appears in the urine as a sulphate, or one of the lower oxides of sulphur, and some of it is even converted into sulphuric acid, and becomes exceedingly useful even in acne cachecticorum when the urine is neutral, or even alkaline. Ringer strongly recommends it as a lotion in menstrual acne, viz.: Sulphur, ℥ i.; glycerine, ℥ i.; water, Oss., well rubbed in several times a day. He says, if efficiently applied it speedily benefits the eruption, even when it has persisted for years uninfluenced by other treatment. It should be used internally at the same time, in doses of 3 or 4 grains, several times a day, made up into a pill with ¼ or ½ grain of aloes when there is amenorrhœa, constipation, biliousness, etc.

The *iodide of sulphur*, from its resolvent properties, is most useful in acne indurata and rosacea; in very obstinate cases ¼ or ½ grain doses may be given internally, and increased to 1 or 3 grains, aided by an ointment made of 5, 10, or even 30 grains to the oz. of cerate.

The *green iodide of mercury* is also most useful in the indurated variety, especially when there is obstinate chronic disease, even induration of the liver or some other organ. It may be given internally in doses of ¼ or ½ grain, combined with ext. of conium or aloes; and applied externally, 5 to 10 grains to the oz. of cerate.

Corrosive sublimate has been given internally in doses of $\frac{1}{10}$th or more of a grain; or in teaspoonful doses of a solution of 10 grains, with an equal quantity of muriate of ammonia in a pint of distilled water. A good lotion is made with 5 to 10 grains in an oz. each of spts. of rosemary and alcohol, and 6 ozs. of mist. amygdal. amaræ. But I prefer the *ammonio-chloride of mercury*, using only 5 to 10 grains instead of the usual 40 grains to the oz. of cerate. But this remedy and arsenic and cantharides should be kept for the most obstinate and rebellious forms. It is said, if the plug in the sebaceous glands becomes saturated with serous effusion, it is easily removed; the above and other irritating remedies are said to accomplish this; while suppuration has been hastened by antimony when this progressed very slowly and too tediously.

Such, Mr. President, are the principles of treatment which I prefer; viz., using the carefully selected remedy internally and externally, and having a careful regard for all internal and constitutional derangements.

Dr. Benjamin Howard spoke as follows:—

After the exhaustive paper of Dr. Bulkley, and the able remarks of the gentlemen who followed, nothing remains to be added. I am tempted, nevertheless, to say just a word; because, in the first place, I differ as well as agree with some of the views just expressed; and because, in the second place, like almost every member present, perhaps, I have a cherished remedy which surpasses all others in my own estimation. The leading points of interest in this discussion will be covered, if, for convenience, we ask concerning acne, 1st. What is it? 2d. What causes it? 3d. What will cure it? Acne consists in a retention within a sebaceous follicle of its own proper secretion, with or without changes in the sac or its contents. Distention, congestion, or inflammation of the follicle may follow, and the contents may degenerate, be mixed with pus, or desiccate. Within this pathological range all the ordinary forms of acne are included.

As to the cause of acne, I should be inclined to differ from my friend Dr. Weisse. I think it is incorrect to ascribe acne to the irritation of the follicular membrane by its own secretion. If there be a morbid sebaceous secretion, there must before that be a morbid follicular membrane. Correct or incorrect, the statement does not touch the cause of acne, but, if correct, deals with the disease only. The imprisoned secretion, the changes occurring in it, the inflammation of the sebaceous follicle—the first, always, and the two latter conditions, if present—belong in no sense to the causes, but to the disease itself.

Looking at the list of causes quoted upon the diagram before us, we cannot dispute them, but they seem sufficiently numerous. I am sure we have all seen hundreds of persons, moreover, exposed to sunshine, cosmetics, filth, and nearly all the other reputed causes, who nevertheless had no acne. On the other hand, we must all have met with cases of the worst sort where these reputed causes were scrupulously avoided. The less we say about any single cause of acne, the better perhaps we shall agree. Soap and sunshine are both reputed by one to be a cause, and by another to effect a cure. The most we can claim to know in the matter of causation is, that there are certain combinations of coincident conditions of which the different forms of eruption of which we are speaking are, respectively, what the disease used to be termed, "the *acne*." *Locally*, the condition most favorable to it is that which most promotes accretion, and closure of the excretory ducts of the sebaceous follicles, so as to cause imprisonment of their proper secretion. Among the endless variety of *constitutional* causes, I believe pubescence and constipation are the most constant.

Treatment.—I fear the confession of so many remedies is but poor commendation of our knowledge. Of local applications I think I have overlooked none, but have used them all in their turn, including washes of the bichloride, even to vesication; but in no case have I observed them to have any special value. If evulsion can be practised without too much irritation, the worst follicles may be emptied at the outset, as they refill with decided advantage. In addition to this, anything which tends to prevent desiccation of the orifices of the ducts, and keeps the skin pliant, will meet the leading indication. *Constitutional* treatment must be the great reliance, and should be directed chiefly to whichever of the abnormal conditions is predominant—pubescence being amenable only to time, however well or ill the treatment. Oftentimes the first doctor must be content to be the last, while in the estimation of the patient the last is just as sure to become the first. Next to pubescence, I think the most common coincident condition is constipation; and this brings me to the revelation of my much-cherished remedy, which usually consists simply of aperient doses of cream-of-tartar. It makes an agreeable drink, and is taken morning and evening, in quantities which are sufficient in each case to be very slightly aperient. If the patient suffers also from

indigestion, especially combined with acidity of the stomach. I prescribe: R. potass. bitart. et soda. ʒj.; rhei pulv., gr. x.; bismuth subnit., gr. x.; soda bicarb., ʒi. M. Divide in pulv. x. Take one powder three times a day.

With the use of these remedies, I have rarely had a case which did not gradually improve; while in the majority of cases the disease has quite disappeared. Explanation I am unable to offer, except that such an aperient, some time continued, may, by its derivative action, promote improvement.

I would say one word respecting the use of arsenic and the more violent remedies in this disease. Whatever benefit they are calculated to afford can come only from their long-continued use; and then, while locally the benefit is very uncertain, the risk to the general health may be quite hazardous.

As in the so-called "operations of convenience," so here, I think we are not justified in attempting a cure by remedies which are more perilous than the disease; therefore, in the present state of our knowledge, such treatment in acne is not to be commended.

Dr. Edward L. Keyes gave the following views:—I have but little to add to what has already been said. I always approach a case of acne with respect; often with a lack of confidence in my power to afford any very considerable speedy relief to the patient. But while I hold acne to be an affection difficult to cure, yet I believe there are few cases which may not be considerably, often wholly, relieved by judicious treatment and unremitting care.

I am in the habit of commencing the study of a given case by a careful review of the family history of the patient. I believe that the tendency to acne is very often inherited, and that such inherited tendency is to be ranked prominently among the predisposing causes. While I cannot but consider acne as being often in the young a signal of sexual distress, of unqualified or perverted sexual yearning, perhaps often unrecognized by the patient; and while I believe in a connection between this cutaneous affection and certain uterine derangements, functional or otherwise, yet neither of these conditions are necessarily attended with acne; nor indeed will digestive derangement, nor any given course of diet, produce acne in every case. Where there exists, however, a family predisposition to acne, an eruption will readily be occasioned by the intervention of any of the numerous adequate exciting causes.

I have marked a tendency to the inheritance of acne in many cases which I have encountered. I have now two sets of cases under my charge where the cross inheritance is plainly and beautifully marked. In both families the boys only are affected, while the girls have escaped, and in both the inheritance is derived through the maternal branch of the family.

When I can discover, in studying a case of acne in a young person, that an older brother or sister, or, indeed, an ancestor, has suffered from the same malady, I am accustomed to derive from the character, course, and duration of the latter case, a valuable aid to prognosis for the case which applies to me for treatment.

I have been forced by observation to an acceptance of two frequently active diathetic predisposing causes to acne—these, the scrofulous and the gouty. The former predisposes to acne punctata, seborrhœa, dry and moist, acne simplex and indurata, and these especially in youngish and middle-aged subjects. The gouty diathesis predisposes, later in life, to acne rosacea and acne simplex.

The previous discussion renders it unnecessary for me to speak further of my views as to the etiology of acne. Suffice it to say, I believe it to be far more often an expression of internal disorder than a mere local affection.

The fulness of the discussion also relieves me from any extended remarks regarding treatment. I endeavor to obtain in all cases a good hygiene for my patient, and a regularity as nearly perfect as possible of all his habits, mainly regarding eating, sleeping, and the intestinal discharges. I believe in the avoidance of sweets, liquors, all fried articles, pastry, and all kinds of food of difficult digestion.

The more healthful exercise in the open air the patient can take, the better. I believe, further, in the curative power of a well-regulated sexual hygiene. Of internal remedies, cod-liver oil holds a high rank, especially with the scrofulous and debilitated; arsenic, I think, does good in many cases where it is easily digested without disturbing the stomach. *Locally*, I like the action of hot water with a little bicarbonate of soda added, and subsequent friction with a soft towel, and some milder stimulating application afterwards; from time to time perhaps using powerful local irritants, especially in acne rosacea.

Dr. Robert W. Taylor:—My experience in the treatment of the various forms of acne has led me to the conclusion that although we can, by various internal and external means, materially benefit or cure our cases, yet that they are quite rebellious to treatment. As to the origin of acne, I am disposed to favor the views which were, I believe, first enunciated in America by Dr. William H. Draper, namely, that acne, as well as other skin diseases, were caused by malassimilation, or, as expressed by Dr. Bence Jones, as errors in oxidation of the tissues. I am very skeptical as to the origin of acne in uterine derangements, and do not believe that uterine catarrh or flexions of the uterus have any influence in their causation; nor have I been able, though I have studied the matter carefully, to make up my mind that any connection existed between menstrual disorders and acne.

I would call attention to the fact that acne is very often aggravated by sea-air, as experienced by persons who for pleasure reside temporarily at the seaside; this point may be of benefit sometimes in a prophylactic point of view. There is a form of acne which is sometimes seen which is not well described in the books, and as it demands a peculiar treatment, it is well to describe its features. It most properly belongs to the indurated type, but unlike that in which the cell-proliferation around the follicles occupies the deep strata of the derma without producing much salience, or if salience is produced, it is not regular and clearly defined; whereas, in the variety I speak of, the cell-proliferation around the follicle produces an elevation which is markedly conical, and, of course, salient, constituting a well-defined papule. The area of these papules is about one line on an average, with a similar measurement as to height, and this may be capped by a minute quantity of pus. Their color is a dusky red, rather coppery, hence liable from color and shape to be mistaken for a syphilide. They generally run an indolent course, involve the deep tissues, and become surrounded by a dense base, and after their final disappearance leave an unsightly cicatrix. The usual site is around the mouth, and they do not have the typical appearance in other localities. For this variety, which, as I say, is rare,—we have had about four examples at the College Clinic,—internal treatment is useless, while local treatment is of decided benefit, as producing small cicatrices in the place of the ugly ones left upon resolution of the lesion. I have found that the very best means of treatment is to bore each papule through

the centre with a *flèche* of nitrate of silver, being careful to thoroughly reach every portion of the papule. After the boring process I order mild lead lotions or emulsion of almonds. In a fortnight the charred papule is thoroughly destroyed, and a cicatrix rapidly forms as I have described. I have tried in one case the application, by boring, of a red-hot needle, but the resulting cicatrices were not as small as when I used nitrate of silver. I should think that perhaps the galvano-cautery might be of benefit in these cases. As to treatment, I am much in favor of local measures. In applying lotions and outward applications generally, the essential point, in my opinion, is to stimulate; and I think that many cases of unsuccess of remedies is due to the fact that lotions are too mildly applied. In acne simplex, which, by the way, is sometimes troublesome in consequence of new crops of papules constantly appearing, I have found benefit from preparations of sulphur, particularly the lotion recommended by . . . . , which consists of two drachms of lac-sulphur, two fluid drachms of spirits of camphor, to four ounces of water. This must be rubbed firmly into the skin and allowed to dry over night, and in the morning it should be slightly anointed with cold cream. I have derived benefit from iodide of sulphur ointment, and lotions of bichloride of mercury, in strengths of two to five grains to the ounce of fluid. At the College Clinic, and in private practice, in cases of acne with much induration, I have seen very marked benefit follow the application of a solution of caustic potash, from twenty to forty grains to the ounce. This is to be freely applied to the spots and allowed to dry, and afterwards washed off in very hot water. This is done at night, and the next day the face is smeared with cold cream. My friend Dr. Draper is much in favor of this treatment, and uses it very frequently at the Clinic.

I think that although acne is a troublesome affection to treat, there is not any necessity for such an amount of polypharmacy as is expended on it, but that relief can be obtained by preparations of sulphur, iodine, mercury, and potash; and I think that these agents, with proper vehicles, are all-sufficient. I have seen benefit from mild ointments of red oxide and of the deuto-iodide of mercury, and in many cases have had good results from the application of mercurial plasters. I have been disappointed in the use of diachylon ointment as recommended by Hebra; it produces very slow and unsatisfactory results. In acne rosacea of the nose, the scarifications recommended by Hebra are an absolute necessity, and often work admirably. Besides stimulation, as regards external measures, there is also another important point to observe, namely, not to change the application too frequently, but to continue vigorously on until the remedy in use has had a fair trial. Many cases of unsuccess are due to the use of remedies for too short a time. As regards internal treatment, I am fully in accord with Dr. Bulkley, which he has so clearly put forth in his admirably complete paper.

Dr. Salvatore Caro said that the remarks he was about to make would be relative to three points:—

Although atmospheric influence, particularly solar heat, is one of the exciting causes of so-called acne solaris, on the other hand, the sun is one of the therapeutical agents in its cure. He received this information from one of his female patients whom he was treating for two years, for acne rosacea on her chin. There was nothing abnormal about her, and the digestive organs were in good condition. Uterine recurrences regular. No mental trouble. Surrounded by luxuries, but indulged with discretion. All the remedies enumerated by the previous speakers were used externally and internally, but without effect.

Being in the country, she took a sail on Lake Mahopac under a very hot sun. Being unprepared, her face was burned, particularly the affected spot, which was blistered; before evening a free discharge commenced —as she remarked—"of a serous fluid, rather thicker and more profuse than usual." About three or four days afterward, the discharge commenced to cease, and by it she was cured of her trouble. The application of cold cloths, previously wrung out from cold water, constituted the local medication during the period of discharge.

On visiting her, on her return to the city, he was surprised to find her cured, and congratulated her upon the success of his last prescription, namely, "Donovan's solution." She remarked that the sun, not the medicine, had effected the cure, and related the above history.

Now, in the treatment of obstinate cases, not omitting internal remedies in each individual case, he concentrates gradually the rays of the sun through a lens upon the affected part, until the whole periphery is well burned. In a short time the skin becomes intensely red, and small vesicles, full of serum, commence to appear; they discharge voluntarily for three or four days, when the healing commences, with final cure. The cold application is the best soother for the pain caused by the heat, and is an effectual help to the free secretion. If the acne is only a follicular affection of certain parts of the skin, with abnormal secretion, in his opinion the blistering action of the sun is the best remedy, rather than lotions or salves. The scorching process is painful; but, limited as are the facts, he considers it worthy of consideration.

His second remark was on the influence of certain articles of food in producing acne. The author of the paper stated that macaroni was one of the articles favorable to the production of acne; without contradiction, he would state that, from personal knowledge, acne is scarcely visible throughout Italy, where macaroni is plentifully used; but in Romagnia, where it was not so much consumed, acne is more prevalent. If this is owing to the deficiency of macaroni, or the abundance of malarious fever which exists at all times of the year, producing as a consequence gastric disturbance, hypertrophy and atrophy of the liver and spleen, he cannot say.

In regard to the new name given to acne by Dr. Weisse, namely, *folliculitis*, he would say that Dr. Barbera (if his memory serves him correctly), in his "Clinical Dermatology," makes a classification of "acne folliculosa," proving that the follicles are the seat of the disease; but he adopts the name of acne, following the style of Aezio.

In some forms of acne simplex he agrees with Dr. Howard, that the let-alone treatment is the best.

Dr. Bulkley remarked that he had noticed that gout and rheumatism were predisposing causes, as mentioned by Dr. Keyes, and also believed in the internal origin of acne.

Dr. James L. Brown, in answer to a question of the President, whether he had found acne in his cases of uterine disease, replied, that in his experience, there was no connection between these affections. He referred to a peculiar kind of diet favorable to its production, and especially the eating of buckwheat cakes.

The President said that if a woman should call upon him, with this affection, between twenty and thirty years of age, unmarried, he would inquire about the bowels and the state of the kidneys before inquir-

ing about any uterine derangement; then he would inquire into that, and see if the menstruative secretion was normal.

In the case of a married woman, with acne, he would find out first whether there was ulceration of the uterus, or any uterine difficulty, or whether the kidneys were at fault, and then the treatment would be directed accordingly. In affections of the kidney he would give acetate of potash, or a pill of aloes et ferri; in inaction of the skin, the spts. of Mindereri.

He thought there was a direct connection between acne and uterine affections, although in many cases there was no visible connection. The eruption around the mouth, mentioned by one of the gentlemen (Dr. Taylor), perhaps was more marked in those patients with affections of the uterus.

The announcement was made that Dr. Austin Flint, Senior, would read a paper before the Academy, November 21st, on "Contribution to Pulmonary Tuberculosis."

The Academy then adjourned.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

(*Continued from page 32.*)

ADDRESS OF PRESIDENT ELECT.

Stated Meeting, Nov. 25, 1872.

DR. ELLSWORTH ELIOT, President, in the Chair.
DR. ELLSWORTH ELIOT made the following remarks:

Gentlemen, Members of the Medical Society of the County of New York:—The candidate who is elected President of the Medical Society of the County of New York, is called to a position of honor for which he may well feel most grateful; to one of responsibility from which he must shrink.

To-night we may look back to the year 1788, when this organization, under the name of "The New York Medical Society," had its beginning; to the year 1806, when Nicholas Romayne was elected "first President under its new act of incorporation." At the date last mentioned our manuscript records begin, and the history which may be gathered from them demonstrates a great power wielded, and important acts performed—acts which, constituting monuments in our history, will remain a part thereof as long as our city shall take an interest in medical science.

Within a year from its incorporation, the members of the Society, then embracing every physician and surgeon in the city who had any authority to practise, and numbering a few over one hundred, organized the College of Physicians and Surgeons, and they became its Board of Trustees. A body so large and unwieldy could found, but they were not equal to the management of, a school of medicine, and another plan was adopted. Although the best feeling has not always existed between the parent and child,—for they have had serious quarrels, even "war to the knife,"—their differences were long since settled, and for many years they have dwelt together in peace.

Again, when an act of incorporation for the University Medical College was asked from our State Legislature, Prof. Paine came to this Society for an indorsement of the proposed institution, and it was cheerfully given.

To have been thus instrumental in laying the foundations of two of our medical colleges is a matter for congratulation; but, without attempting anything like a history, let us pass on to another chapter, of more direct importance to the medical profession in the United States.

The project for the formation of our National Pharmacopœia was submitted first to our County Society by Dr. Lyman Spalding, in 1817. After a vast amount of preliminary work by various organizations and individuals, a convention was held in Washington on the first day of January, 1820, of which Samuel L. Mitchell, one of our most prominent members, was chosen President. Before the close of the year "The Pharmacopœia of the United States of America" was published. The Massachusetts Medical Society had published one in 1808. The New York Hospital had published theirs in 1816. A variety of pharmacopœias and dispensatories had been introduced from the old world, and were made a basis for the preparation of medicines,—one in one shop, and another in another. When the uncertainty which must have existed in regard to medicinal preparations is borne in mind, we cannot estimate too highly the value of a standard generally recognized. The plan first adopted contemplates a revision once in ten years; and every tenth year we therefore have the work written up to a recent date. As precision is of the utmost importance, physicians should conform to its nomenclature in writing their prescriptions. The teachers in medical schools, the authors of medical books, and the writers in medical journals should depart therefrom only so far as new discoveries compel.

It is pleasant and profitable to take glimpses at the past, that we may gain wisdom for the present and the future, which more intimately concern us. Under able presiding officers, the Society has become, probably, the first county organization in the land; and so long as New York is the principal city among our cities, so long should it hold the foremost rank.

Our existence and prosperity should show the necessity of such organizations in every county of our States, and State societies should be composed of representatives from the county societies therein, as is the rule in many if not every State which has organized a State medical society. And here the suggestion may not be out of place, that if our American Medical Association could be so remodelled as to bear the same relation to the State societies that the county societies in New York sustain to our State society, an organization more effective for good would be the result. Each county now sends to the State society, which meets at Albany annually in February, as many delegates as it has representatives in our State Assembly. The county of New York, with twenty-one assemblymen, sends from its county society twenty-one delegates; and all delegates, excepting those who fill unexpired terms, hold their positions for four years. Sixteen permanent members are annually elected from those who have served as delegates, two "from each of the senatorial districts established in 1836," when there were eight senatorial districts in the State, the city and county of New York, the counties of Richmond and Kings, being the first. Our Society has fewer permanent members elected annually in proportion to its size than any other part of the State, not less than forty being now eligible from the societies of New York, Kings, and Richmond County. An election as delegate or permanent member is now regarded so honorable that the competition for those positions is great. How differently stands the matter with the American Medical Association! Our delegations to this body are

never full, and every delegate may continue permanent member by the payment of annual dues.

Let our National Association be composed of as many delegates from each State society as there are congressmen; let a limited number be elected annually as permanent members from congressional districts, as is done by our State society, and the position would become desirable to our foremost men.

The forthcoming year should be one of progress. Our membership should be greatly increased. In this way, every member can do something to enhance our prosperity. He should not rest until every physician in New York is enrolled as a member. A law passed in 1827, and still unrepealed, reads as follows: "The President of every County Medical Society shall give notice in writing, to every physician and surgeon not already admitted into such society, within the county in which the society of which he is president is situated, requiring such physician or surgeon, within sixty days after the service of such notice, to apply for and receive a certificate of admission as a member of such society." How far this law has been obeyed by my predecessors I am unable to say, but our county has increased so largely since the enactment of the law read, that however practicable it may have been at that time, its observance would scarcely be expected of the present incumbent. It has been suggested that a circular should be issued calling attention to the existence of this law, that all may be informed of their duties and their privileges. Meanwhile let every member exert himself to persuade those who are not of us to seek membership without delay.

The organization of the Society contemplates the performance of executive business, in the main, by the Comitia Minora, and hence the meetings of the Society should be devoted to scientific pursuits. If we depart not from this course, our prosperity will continue. If we turn aside, and become involved in quarrels of a personal or ethical character, we shall lose ground. Our Society has had its dark days, and, so far as I have been able to learn, from this cause solely. Quarrels have no attraction for the lovers of science. By all means the Society should maintain a high standard in regard to ethics, and sever connection with all violators of its code; but this kind of business could be done at adjourned or special meetings, so that the main object we have in view should not suffer. If the section in our code of ethics having reference to this matter were strictly followed, our societies would seldom have employment as disciplinarians. "Differences between physicians" "should be referred to the arbitration of a sufficient number of physicians," "or when both parties are members of the medical society of their county, to the censors." Cases will occur when the Society at large must pronounce an opinion upon questions of importance. For instance, recently this Society and our State society have declared that any member seeking redress by a legal process from another, supposed to have acted unfairly, is unworthy of membership. Let us hope that there will be nothing to mar good feeling from this time, and that members will seek the adjustment of difficulties through friends whose judgment and integrity command their respect.

We begin our new year on an eventful day in the history of the city—the day of the month on which it was evacuated by the British forces in 1783. Several of the surgeons in the opposing armies were afterwards among the founders of our Society. To their names, enrolled nearly seventy years ago, is appended a note to this effect: "Late surgeon in the Revolutionary war," etc. As then it was, so now it continues. However much opposed elsewhere, all here unite in a common cause. Every legitimate practitioner of our art is welcomed, and asked to join with us in advancing the standard of medical science.

At the close of the meeting, Dr. Wm. C. Roberts rose, and, after some preliminary remarks, proposed the following resolution:

Resolved, that the Medical Society of the County of New York tender to their late President, Dr. Jacobi, on his retirement from the office he has so long and worthily held, their acknowledgment of the able manner in which he has performed the duties devolving on him; his courtesy of demeanor, and zeal in behalf of the Association.

That he carries with him their warm appreciation of his professional attainments and literary labors in the cause of medical science and philanthropy, and their best wishes for his personal health, happiness, and prosperity.

The resolution was unanimously adopted.

THE PAPER OF THE EVENING.

Dr. A. D. Rockwell then read the paper of the evening, entitled "Central Galvanization."

On motion, the meeting was adjourned.

New Instruments.

REMARK ON A VAGINAL SPECULUM.

By G. WACKERHAGAN, M.D.,

SURGEON TO SOUTH BROOKLYN DISPENSARY.

I DESIRE to call the attention of the profession to a self-retaining vaginal speculum which I have had constructed, with a view to facilitate uterine operations with the patient on the back.

I will simply give a description of the instrument, and leave the practitioner to decide as to its superior advantages. The inferior blade is solid, and 4½ inches

long by 1½ inch wide; it is connected to a sliding frame by a hinge-joint. The curve at the base of the blade is the same as in the ordinary cylindrical speculum.

The superior blade is also solid, and is 3½ inches long; this blade has a longitudinal slide attached, by which it may be lengthened or shortened, and is of great assistance in directing the neck of the womb in the most desirable position for the application of topical remedies or surgical operations,—especially when that organ is anteflexed. The sliding frame is 2¼ inches in length by 1½ inch wide, and is directed towards the pubis; the anterior blade is connected with this, and by a sliding movement up or down in the direction of the arc of a circle, permits the depression of the perinæum to any desirable extent.

The speculum represented in the cut is prepared for introduction by drawing in the longitudinal slide and placing the blades in contact, after which proceed as in the use of the common cylindrical speculum.

The posterior blade is then held firmly by the thumb and index finger of the left hand, while the cross-bar of the sliding frame is pulled forward with the right, until the blades describe an angle of about 35°, when, by a touch of the screw on the left, they are held in position. Then the inferior blade is depressed upon the perinæum, at the same time the superior blade is slid up on the frame and fastened by a screw on the right. Last of all, the longitudinal slide is pushed back, bringing the neck of the womb into view. In order that the anterior wall of the vagina may be more readily elevated, I am in the habit of instructing patients with uterine disease to empty the bladder before presenting themselves for treatment.

I wish here to state that I have copied somewhat from the very excellent instrument of Dr. Byrne, to whom is due the credit of advancing new principles in the construction of vaginal specula.

My speculum is manufactured by Messrs. Tiemann & Co., who have given me every satisfaction in its construction.

366 Clinton Street, Brooklyn, *October*, 1872.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from December 19, 1872, to *January* 4, 1873.

Bill, J. H., Surgeon, granted leave of absence for thirty days, with permission to apply for thirty days' extension. S. O. 348, War Dept., A. G. O., December 30, 1872.

Byrne, C. C., Surgeon, granted leave of absence for twenty days. S. O. 243, Dept. of the East, Dec. 19, 1872.

McClellan, E., Asst. Surgeon, assigned to duty at Lebanon, Ky. S. O. 266, Dept. of the South, Dec. 14, 1872.

Phillips, H. J., Asst. Surgeon, granted leave of absence for thirty days on Surgeon's certificate of disability. S. O. 230, Mil. Division of the Pacific, Dec. 12, 1872.

Vickery, R., S., Asst. Surgeon, assigned to duty at Jackson Barracks, New Orleans, La. S. O. 196, Dept. of the Gulf, Dec. 14, 1872.

Mackin, Charles, Asst. Surgeon, relieved from duty at Fort Macon, N. C., and assigned to duty at Columbia, S. C.

Matthews, W., Asst. Surgeon, assigned to temporary duty at Willett's Point, N. Y. H. S. O. 243, C. S. Dept. of the East.

Munn, C. E., Asst. Surgeon, assigned to duty at Fort Adams, R. I. S. O. 245, Dept. of the East, Dec. 23, 1872.

Medical Items and News.

Dr. Austin Flint has been elected President of the New York Academy of Medicine.

New York Pathological Society.—The following officers have been elected for the ensuing year:—*President*, Dr. Erskine Mason; *Vice-President*, Dr. E. L. Keyes; *Secretary*, Dr. Geo. F. Shrady; *Treasurer*, Dr. John H. Hinton.

American Association for the Cure of Inebriates.—At the annual meeting, held in New York, the following officers were re-elected for the ensuing year: *President*, Dr. Joseph Parish, of Philadelphia; *Vice-Presidents*, C. J. Hall, of Illinois, and Otis Clapp, of Massachusetts; *Secretary*, Dr. D. G. Dodge, of New York; *Treasurer*, Dr. T. L. Mason, of New York,

Massachusetts General Hospital.—Drs. Geo. T. Shattuck, C. Ellis, S. Cabot, H. K. Oliver, Jr., A. Coolidge, F. Minot, H. J. Bigelow, R. M. Hodges, Geo. H. Gay, and Samuel L. Abbot, the physicians and surgeons of the Massachusetts General Hospital, presented an elegant silver salver to Dr. Benjamin S. Shaw, on his retirement from the position of Resident Physician, which he has ably held for the past fourteen years.

Bazin.—On account of the advanced age of M. Bazin, who has so long been connected with the Hôpital St. Louis, he is obliged to retire from his post which has been so worthily filled. A bust of the lecturer is to be placed, by his present and former pupils, in the theatre wherein his clinical lectures were given.

A Fee to be Desired.—A fee of ten thousand florins, or about $50,000 in gold, has been handed Professor Pitha, of Vienna, on the recovery of young Baron Todesco, the only son of a millionaire.

Catacombs of Paris.—This vast charnel-house contains the remains of about three millions of human beings. The Catacombs, dating from the year 1784, are situated in the south of Paris, and are about 3,000,000 square metres in extent, or about one-tenth of the superficies of the whole city, and run under several streets.

Honorary Fellows of the Obstetrical Society of London.—At a late meeting of the Obstetrical Society of London, the following gentlemen of this city were elected Honorary Fellows of the Society: Drs. Fordyce Barker and T. Gaillard Thomas.

Death of a Noted Southern Surgeon.—Dr. Warren Stone, long a distinguished surgeon of New Orleans, Louisiana, died in that city, December 6, 1872, aged 65 years.

Renewal of Teeth.—M. Magitol (*Canadian Pharm. Journ.*) observes that arsenious acid, when internally administered, possesses the curious property of causing the renewal of certain parts of the teeth.

California College of Pharmacy.—A course of lectures in this new school of pharmacy, located at San Francisco, will commence this winter with the follow-

ing faculty:—Chair of Pharmacy, Wm. T. Wenzell; Chair of Chemistry, Max Tschirner; Chair of Materia Medica, Wm. Searby; Chair of Botany, H. H. Behr, M.D.

St. Elizabeth's Hospital and Home, Utica, N. Y.—The fourth annual report of this institution, organized in 1866 by Mother Bernadina of the Order of St. Francis, and incorporated in 1870, gives the following exhibit:—The hospital is under the supervision of Sisters of the Order of St. Francis, an order six hundred years old, and which is under no other control than that of its own officers. The object is to provide for the medical and surgical care of all persons who may apply for relief, and to furnish a home for the aged and infirm of both sexes. During the year ending Oct. 1, 1872, 125 patients were treated in hospital. Total number of patients received since the opening of the hospital has been 336; males, 129; females, 207; and children under 15 years of age, 26. Of these, 152 recovered; 81 improved; 32 unimproved; 45 died. The most important diseases were remittent fever, acute rheumatism, chronic rheumatism, alcoholism, phthisis pulmonalis, Bright's disease, and various eye diseases. Of the latter there were 22 cases; 8 recovered, 8 improved. Only one death occurred after the eight operations on the eye. This was a case of senile cataract in a patient 82 years old. After the operation, by the modified linear extraction, the patient could see, but she died from paralysis the sixth day after the operation. The following gentlemen composed the *Medical Staff:—Consulting Surgeon*, Alonzo Churchill, M.D.; *Visiting Physician*, Joseph E. West, M.D.; *Physician to Lying-in Department*, Thos. J. Bergen, M.D.; *Surgeon in Charge*, Edwin Hutchinson, M.D.

Albany County Medical Society.—The officers of this Society for 1873 are as follows:—*President*, A. Van Derveer, M.D.; *Vice-President*, A. W. Shiland, M.D.; *Secretary*, F. C. Curtis, M.D.; *Treasurer*, W. H. Murray, M.D.; *Delegates to State Medical Society*, Drs. C. A. Robertson, D. V. O'Leary, A. Fowler, and H. March.

Death of Dr. Daremberg.—This professor of medical history at the Faculty of Paris died recently at the age of 55 years. The works of Hippocrates, Oribasus, and Galen were translated by him. He edited the *Collectio Salernitana*, and wrote many separate treatises, besides his great work, *Histoire des Sciences Médicales*.

Life Insurance.—Wm. Barnes, Superintendent of the Insurance Department of the State of New York, was elected by the Statistical Congress, lately held in St. Petersburg, to prepare a work on statistics of life insurance in the whole world.

Tyndall.—The brilliant course of lectures of Professor Tyndall have more than satisfied his overflowing audiences at Cooper Institute. It is to be hoped this distinguished *savant* will again visit our country and favor us with similar lectures.

Mental Vigor in Old Age.—It is said of Arnauld, the Jansenist, that he wished his friend Nicole to assist him in a new work. Nicole replied: "We are now old; is it not time to rest?" "Rest!" exclaimed Arnauld, "have we not all eternity to rest in."

A Witness necessary in the Administering of Anæsthetics.—A London correspondent of the *Dental Cosmos*, of Dec., 1872, mentions the recent charge of indecent assault by Caroline Pope, a servant, against Jas. T. Grant, dentist, at the Jersey (Channel Islands) police court. She states that "gas" was given to extract a tooth, and while she was under its influence he grossly outraged her. There was no evidence of a rape having been attempted, and many witnesses gave the dentist the highest moral character. He was admitted to bail in the sum of £250 for future trial. This case illustrates once again the extreme danger of administering anæsthetics to women without the presence of a witness.

Medico-Legal Society of New York.—By a vote of the Society, the stated meetings are changed from the second to the fourth Thursday in each month.

Dr. F. D. Weisse will read, January 23, 1873, a paper on "The Obligations and Responsibility of the Administration of Nitrous Oxide Gas, and other Anæsthetics."

Suicide of a Prague Professor.—Dr. Treitz, long the popular Professor of Anatomy in the University of Prague, recently committed suicide by means of cyanide of potassium.

Gen. Meade.—According to the *Philadelphia Medical Times*, the cause of General Meade's death was the formation of a heart-clot during an attack of pneumonia.

The Hospital at Jerusalem.—This hospital, under the care of Dr. Chaplin, is almost supported by the English Society, and is in excellent working order. During the past year, 7,477 out-patients were seen at the dispensary, the majority being women. In two years about 10,000 visits were paid to patients at their homes.

Ovarian Cyst in a Young Subject.—A. F. Carr, M.D., of Goffstown, N. H., writes to the *Medical and Surgical Reporter*, of Nov. 16, 1872, that he attended the post-mortem of a child a little less than three years of age, whose left ovary was enlarged to the size of a half-gallon jug, and estimated to weigh nine pounds.

Gallatin.—Dr. A. H. Gallatin, of New York, has been appointed Director of the Laboratory, in connection with the system of free scientific instruction at the Cooper Union.

A Reminiscence of Dr. Valentine Mott.—Several years ago a late Professor of the New York Medical College often visited old Dr. Mott, and at one of these occasions he saw the medical pocket-case, with small bottles, of the visitor, gotten up for any medical emergencies in the night. He exclaimed:

"Oh, doctor! I hope you have not turned homœopath?"

"Not at all, Dr. Mott; these are the regular allopathic remedies."

"That is right; it would grieve me to see you fall so low; but why these homœopathic bottles?"

"In order to have a druggist's shop in a small compass, and not be obliged to send to a druggist when called out at night."

"Well, that is right; but let me see your selection." Then a critical examination of every bottle took place, and the choice approved as very judicious, till the last bottle was reached, without label, containing white pills, when Dr. Mott said:

"And what is there in this bottle?"

"I have to confess to you, Dr. Mott, that these are plain sugar pills."

"Those are the best pills you have in your whole box," was the remark of the great surgeon.

New York Medical Library and Journal Association.—At the stated meeting of this Association, held December 6, 1872, Dr. Alfred Underhill, the retiring President, made appropriate remarks, in which

stress was made on the following points: The origin of the Association, eight years ago, by a few medical men, at the residence of one of the older members, and its establishment on liberal principles. It is now acknowledged to be not only an exceedingly useful, but an indispensable institution to the medical profession of New York, so much so, that some of our neighboring cities and towns have similar ones. Although the organization has proved successful, and possesses the sympathies of a large proportion of the profession, it is not claimed that its success has as yet equalled the full anticipations of its founders; but much has been done, and the members have not been idle in crowding the shelves and tables with books and journals, and in attending the Friday-evening reunions, etc. Within the last five years the extensive and valuable libraries of the late Drs. Batchelder and Geo. T. Elliot have been added to the collection. With the present year the association has taken a new start, and finds itself located in exceedingly pleasant rooms, and perfectly free from disagreeable annoyances to which the members had heretofore, in some degree, been subjected. In regard to the future, it is the intention of the Board of Direction to have such an additional number of medical journals, books, and monographs, etc., as the future funds will allow. In closing, the speaker urged the younger members of the medical profession to stand by the organization, as they will reap the larger share of its advantages, and will profit likewise by a familiar intercourse with the profession, thus gaining the valuable experience of their seniors, whose record is already made. The Association had his warmest wishes for its continued prosperity.

Dr. John C. Peters, the President-elect, in the course of his remarks, recalled the names of the former Presidents, viz.: Drs. Delafield, Taylor, Buck, Hubbard, and Underhill,—names connected with all good public-spirited works, and crowned with great professional success. He asked the Officers and Trustees to take a double interest in the welfare and success of the Association, they being the Trustees not only of its present property and plans, but of all the bright hopes and expectations which the founders indulged in when they laid the basis of the present useful and progressive institution. The difficulties and obstacles which were in the way were just enough to excite the interest of the members, without depressing their hopes. The ordinary income was nearly sufficient for the running expenses, but not enough to complete some of the back sets of medical journals, nor to bind up all of them as quickly as was desirable. These important objects could easily be attained by the addition of a few more members to the ranks; and by earnest, proper, and gentlemanly means on the part of each member, it could quickly be brought about. The Vice-Presidents are officers not merely in name, but in fact; and he hoped that they would not merely supply the deficiencies of the President, but would outstrip him in material and scientific work. In speaking of the office of Corresponding Secretary, he thought it was comparatively easy to get the Transactions of the different State Medical Societies, the foreign and domestic health reports, army and navy reports, and the government reports of almost every country. He alluded, among several interesting topics, to the fact that a number of duplicate journals and books of the Association would be for sale or exchange. After thanking the members for the honor conferred upon him, and the trust reposed in him, he said he would hand it down unimpaired to his successor.

Dr. A. Jacobi then made some remarks on "Idiocy."

The Association then adjourned.

American Journal of Insanity.—This journal has entered upon its twenty-ninth year, and is the oldest journal devoted especially to insanity, its treatment, jurisprudence, etc. The October number contains the important paper on "Thoughts on the Causation of Insanity," read by John P. Gray, M.D., Editor, and Superintendent of the New York State Lunatic Asylum Utica, N. Y., at the New York State Medical Society, at its annual meeting, February, 1872, and also before the Association of Medical Superintendents of American Institutions for the Insane, held in Madison, Wis., June, 1872.

The Oldest Hospital Trustee in America.—Dr. R. J. Patterson, of Batavia, Ill., says that M. L. Fisher, President of the Board of Trustees of the Iowa Hospital for the Insane, is the oldest trustee of a hospital in the United States.

A Hospital in Poughkeepsie.—Messrs. Matthew and John Guy Vassar have decided to found a hospital in Poughkeepsie, and for that purpose will invest $100,000. The building will be erected on the corner of Lafayette place and Vassar street.

New York Medical Schools.—This city is the acknowledged medical centre of the United States. Over one thousand medical students are distributed in the three well-known medical colleges, viz., Bellevue Hospital Medical College, College of Physicans and Surgeons, and Medical Department of the University of the City of New York.

American Journal of Obstetrics—With the November number of this excellent quarterly journal, edited by B. F. Dawson, M.D., the subscribers will notice that Messrs. William Wood & Co. have assumed the charge of its publication.

The Professions in Pennsylvania.—According to the census of 1872, the number of physicians in the State are 4,843, clergymen 4,341, and lawyers 3,253; total 11,937.

The Next Meeting of the International Ophthalmological Congress is to be held in New York, in 1876.

Disorders of Menstruation.—Dr. Theophilus Parvin has a clever paper in the September number of the *American Practitioner*, on the "Disorders of Menstruation from Physical Causes." He considers these disorders under the heads of *premature occurrence*, *absence*, partial or complete, *difficulty* and *excess* of the flow.

Southern Ohio Lunatic Asylum.—Dr. S. J. F. Miller, of Cincinnati, has been appointed Superintendent of this institution.

New Insane Asylum in California.—Agreeably to the report of Dr. Thomas M. Logan, Secretary of the State Board of Health, and the Governor of California, the Commissioners appointed to locate a new insane asylum, for the accommodation of 500 patients, have selected high land, embellished by a natural growth of oaks near Napa City. In that locality, according to Dr. M. B. Pond, a resident physician, typhoid fever is scarcely known; intermittent fever not at all, except when imported from abroad. Remittent fevers are more commonly met with, but they only occur as sporadic cases, and not at regularly recurring seasons. During the summer the thermometer ranges from 60 to 72°, with only occasional exceptions, and those lasting only two or three days at a time.

Original Communications.

A CONTRIBUTION TO THE CLINICAL STUDY OF THE ETIOLOGY OF PULMONARY TUBERCULOSIS.

The influence of sex, occupation, and antecedent affections on the causation of pulmonary tuberculosis; based on an analysis of six hundred and seventy cases.

Read at a Meeting of the New York Academy of Medicine, November 21, 1872.

By AUSTIN FLINT, M.D.

I have entitled the paper which I shall read this evening, "A Contribution to the clinical study of the Etiology of Pulmonary Tuberculosis;" and let me at once state the sense in which I use the term pulmonary tuberculosis. I use this term in its common acceptation, as embracing the chronic affection or affections hitherto known as phthisis pulmonalis or pulmonary consumption, together with the comparatively rare cases which it has been customary to distinguish as cases of acute phthisis. My contribution will relate to the etiology of pulmonary tuberculosis in this comprehensive sense of the term, and considered entirely from a clinical stand-point. The basis will be the results of an analysis of *six hundred and seventy cases* contained in my medical records. The larger number of these cases came under my observation in private practice, namely, 448 cases. The remainder, namely, 222 cases, were observed in hospital practice. These cases were observed during a period of thirty-four years. They are all the cases of which I kept notes between the year 1836 and the year 1870. The records in all the cases in private practice were made by myself. This is true of the greater part of the hospital cases; but the histories of some of the latter were recorded by others under my supervision. In every instance the cases were under my observation.

These records, as regards completeness and fulness of detail, vary much. Of some of the cases, the histories are quite full and complete; but of many cases the notes are imperfect and incomplete. Some of the cases were under my observation from the commencement of the disease throughout its whole course, but not a few were observed for a short period only. In a considerable number, the patients not only passed from under my observation, but the subsequent course and the termination of the disease were not ascertained. These defects will not lead into error except in so far as concerns negative facts. In my deductions I shall confine myself chiefly to positive facts, that is, to what is noted, drawing comparatively few inferences from what the records do not contain.

With these preliminary remarks, I proceed to interrogate my cases respecting certain points which bear upon questions relating to the etiology of pulmonary tuberculosis.

1. *The influence of sex in the etiology of pulmonary tuberculosis.*

The sex is noted in 669 cases. The number of male cases, in private practice, was 321; of female cases, 127. In hospital practice, the number of male cases was 187; of female cases, 37. In private practice, there were no apparent reasons why a larger number of men than of women, affected with this disease, should have come under my observation. In hospital practice, it may have happened that my service embraced more male than female patients: the latter fact may, perhaps, explain the discrepancy between private and hospital practice in respect of the disproportion between the male and female patients affected with pulmonary tuberculosis. In hospital practice the male exceed the female cases by more than two-thirds; in private practice the preponderance of males is somwhat less. The greater liability of men than of women to this disease is, however, exemplified in both collections of cases. In the two collections united, the number of male cases was 505; of female cases, 164; the excess of the male over the female cases being very nearly two-thirds.

The result of the analysis as regards sex is at variance with Louis' statistics. Of 123 cases observed by Louis during a period of more than three years, in a service at La Charité, Paris, embracing 48 beds, equally divided between men and women, 66 were women, and 57 were men. From the greater number of women, Louis inferred some causative influence belonging to the female sex. This variation, perhaps, illustrates the liability of such statistics to be affected, at different times and places, by extrinsic circumstances which are not always readily determinable. Whether in Paris, in the years 1821, '22 and '23, there were reasons why more tuberculous women than tuberculous men should seek refuge in La Charité Hospital; or whether the causes of tuberculous disease, at that time, in that city, affected more women than men, and if so, whether this is true of the years which have since elapsed; or, again, whether there are circumstances on the one hand peculiar to France, and on the other hand peculiar to this country, affecting the proportion of men to women who become tuberculous,—these, and other points of inquiry, I shall not undertake to discuss.

2. *The influence of occupation on the etiology of pulmonary tuberculosis.*

Of the male cases in private practice, the occupations were noted in 212. In this number of cases, 70 different occupations are represented. 32 patients were clerks. They constitute a much larger representation than is furnished by any of the other occupations. 4 were book-keepers, an occupation which, as regards hygienic influences, is very similar to that of a clerk. 30 were physicians; but, doubtless, circumstances of a personal character determined the number of representatives of the medical profession, so that this number is not to be considered as any evidence of the influence of this calling in the etiology of the disease. The same is to be said of medical students, the number of the latter being 8. The number of merchants is the largest after clerks and physicians, namely, 15. The next most numerous are lawyers, the number being 14. Farmers come next; of these there were 11. There were 2 law students, and 3 students whose line of study was not specified. 6 patients were clergymen; 7 were Southern planters; 4 were commercial travellers; 3 were machinists; 5 were teachers; 2 were manufacturers; 2 were melodeon-tuners; 2 were railroad contractors; 2 were hotel-keepers; 2 were editors; 2 were publishers; 4 were soldiers, and 2 were sailors. Of the remaining 46 occupations, each one was represented by a single case. The following is a list of these 46 occupations: Tailor, maker of burr mill-stones, doorkeeper, cabinetmaker, joiner, portrait painter, banker, lake captain, engineer, fuller, railroad superintendent, contractor, singing-master, deputy sheriff, varnisher, ship-carpenter, grocer, transportation agent, saddler, agent, real-estate agent, carriage-maker, druggist, livery-stable keeper, hostler,

president of college, peddler, gambler, drayman, architect, carpenter, footman, baker, secretary of insurance company, lithographer, broker, provision dealer, diplomatist, brushmaker, homœopathic practitioner, professor of chemistry, telegraphist, liquor dealer, policeman, harness-maker, and inspector of masonry.

Of the cases in hospital practice, the occupations were noted in 158; and 48 different occupations are represented among these cases. The occupation of a laborer predominates vastly over all others, the number being 69. This is readily explained by the fact that, of those who seek refuge in hospitals, by far the largest proportion belong to the class called laborers. Seamen come next in number; 9 were of this class. Clerks and tailors come next; of these the number was the same, namely, 7. 4 were waiters; 3 were farmers; 3 were boatmen; 3 were butchers; 3 were hostlers; 2 were printers; 2 were blacksmiths; 2 were merchants; 2 were tinsmiths; 2 were servants; 2 were stone-cutters; and 2 were soldiers. Of the remaining 31 occupations, each was represented by a single case.

Reviewing the foregoing numerical facts, the attention is at once arrested by the large number of clerks in the cases in private practice. There is no apparent reason for the great preponderance of patients pursuing this occupation, except that it involves an influence in the etiology of pulmonary tuberculosis. Nearly one-sixth of the 218 cases were either clerks or book-keepers. Now, in a hygienic point of view, the distinctive feature of the occupation of a clerk or a book-keeper is its sedentary character, together with confinement within doors, often in small, heated, and illy-ventilated rooms. The hygienic conditions, as regards diet, mental excitements, habits of temperance, etc., are, as a rule, certainly not less favorable to health than in most other occupations. As it seems to me, it may fairly be concluded that these facts go to show an agency in the circumstances belonging to the life of clerks and book-keepers which conduces to the development of pulmonary tuberculosis. The number of merchants may be considered as having, measurably, the same significance, about $\frac{1}{14}$th of the whole number of cases representing this occupation, which in general involves more or less confinement within doors and sedentary habits. Other occupations involving, to a greater or less extent, the same hygienic circumstances are those of the lawyer, the teacher, the printer, the student, the editor, the publisher, the melodeon-tuner and the clergyman. The number of cases in these occupations collectively, was 40, the proportion being nearly $\frac{1}{4}$th of the whole number of cases. Adding together all the cases representing the occupations just named, the number is 91, the proportion being considerably nearer one-half than one-third of the whole number of cases. If, for reasons which have been given, the physicians and medical students be thrown out, leaving the number of cases 174, the cases representing occupations which involve especially confinement within doors and sedentary habits, are more than half the whole number of cases.

It will be observed that in this analysis I exclude the female cases. The occupation in some of the latter is noted as seamstresses, domestics, etc.; but in the majority of these cases the patients could not be said to have any definite occupation.

Exclusive of the cases which have been enumerated as representing sedentary occupations and confinement within doors, and excluding physicians and medical students, the number of cases in private practice remaining is 83. It is noteworthy that, of these 83 cases, 46 represent each a different occupation. The other 37 cases represent 9 occupations, as follows: Farmers, 11; Southern planters, 7; commercial travellers, 4; machinists, 3; manufacturers, 2; railroad contractors, 2; hotel-keepers, 2; soldiers, 4; and seamen, 2.

Another noteworthy fact is this: of the different occupations (55) represented by these 83 cases, one only involves the habitual inhalation of particles which occasion local mechanical irritation of the bronchial mucous membrane. The occupation referred to is the manufacture of burr mill-stones. Persons engaged in this occupation inhale constantly stone-dust. But the patient who represented this occupation had not for many years been exposed to the inhalation of the dust. This case is one of much interest, and I subjoin a brief synopsis of it.

The patient, when he came under my observation, was about 40 years of age. He had recently had repeated attacks of hæmoptysis, and the existence of tuberculous disease was rendered clear by symptoms and physical signs. His death took place about two months afterward. The antecedent history was as follows: Eighteen years previously, he was engaged in the manufacture of the burr mill-stones, himself working in this occupation. He then had cough and other symptoms which appeared to denote pulmonary consumption. He ceased working in the sheds where the mill-stones were manufactured, and attended exclusively to out-of-door duties connected with the business. Gradually he recovered his health, and he remained perfectly well, excepting occasionally cough and expectoration, having become robust and stout, until he had a perineal abscess eventuating in fistula, for which a surgical operation was performed with partial success. A year afterward, while apparently well, he had a slight attack of hæmoptysis. The hæmoptysis recurred, and was more abundant; cough, with expectoration, followed, and the signs showed solidification of lung when he came under my observation, a week after the first hemorrhage.

The autopsy showed recent pleuritic adhesions on both sides, with numerous small tubercles, patches of tuberculous infiltration, and softened collections in the right lung, the left lung being crammed with miliary tubercles without any infiltration. These appearances were, doubtless, connected with the recent rapid tuberculous disease. In addition, near the apex of each lung was a solid mass of about the size of a hen's egg, somewhat larger on the right than on the left side. These masses, on section, appeared to consist of condensed tissue of a reddish color, rather friable, and contained disseminated calcareous particles. Each mass was enclosed in a thick, firm cyst. The masses extended to the anterior superficies of the lungs, and at their site the surface had a contracted, puckered appearance.

It can hardly be doubted that these masses were connected with the symptoms denoting phthisis eighteen years before the death of the patient, although there may be room for the question whether the affection, at that time, was a truly tuberculous disease or a chronic interstitial pneumonia.

Of the cases in hospital practice, the large number of "laborers" has been already accounted for. The number of seamen is explained by the fact that my hospital service sometimes embraced wards appropriated to this class. In seeking for facts bearing on an etiological influence, therefore, these cases should be excluded. Excluding them, the remaining number of cases is 80. Discriminating among these 80 cases with reference to the occupations which are especially sedentary, and which involve confinement within doors, they are as follows: Clerks, 7 cases; book-keeper, 1 case; teacher, 1 case; tailors, 7 cases;

printers, 2 cases; merchants, 2 cases; shoemaker, 1 case; weaver, 1 case; tinsmiths, 2 cases; confectioner, 1 case; barkeeper, 1 case; lawyer, 1 case; total, 27 cases. The proportion is a little over one-third of the whole number.

An important element in this numerical analysis, as compared with that of the cases in private practice, relates to the circumstances connected with different occupations leading patients to seek refuge in hospitals. I will not, however, enter into a consideration of this element. It is to be noted that clerks and bookkeepers here, as in the cases in private practice, are the most numerous, the number being 8 out of 80 cases. The next largest in number are tailors, 7 out of 80 cases. With the exception of weavers (2 cases), the other occupations are represented each by a single case. The cases which do not represent sedentary occupations with confinement within doors (53) are distributed among 34 different occupations. Of these 34 occupations, 24 have each but a single representative. The remaining 19 occupations are represented as follows: Soldiers, 2 cases; joiners, 3 cases; stone-cutters, 2 cases; hostlers, 3 cases; blacksmiths, 2 cases; waiters, 4 cases; servants, 2 cases; boatmen, 3 cases; carpenters, 5 cases; and butchers, 3 cases.

Making due allowance for the circumstances which determine men of different occupations to resort to hospitals, the result of this numerical analysis of my cases in hospital practice corresponds to that of the analysis of cases in private practice. The general conclusion is, that occupation has an agency in the etiology of pulmonary tuberculosis in so far as it is sedentary and involves confinement within doors. If it be said that this conclusion is in accordance with what is already known, I answer, that the correctness of the conclusion is thereby the more certain. My object is to study, by means of numerical analysis, my cases, without reference to similar researches by others; and if the results of my analytical investigation are in conformity with those which have been already obtained, this is certainly no disparagement of their correctness, nor does it impair their value as a contribution to our knowledge.

3. *The influence of antecedent diseases in the etiology of pulmonary tuberculosis.*

My records, in a considerable number of cases, embrace information respecting the health of the patients prior to the development of the tuberculous affection; and I shall proceed to analyze the cases with reference to antecedent diseases which may be suspected of having had an etiological influence. Here, however, my notes contain only certain "positive facts:" that is, I have not been careful to record the absence of diseases which do not appear in the account of the "previous history." The presumption is, that when the records embrace an account of the previous health, diseases of which no mention is made had not occurred. In other words, it is probable that these diseases occurred only in the cases in which it is so stated; but I cannot assert this with positiveness. Moreover, in not a few of the records, the account of the previous health is either evidently incomplete, or wanting. With regard to antecedent diseases, therefore, I shall not assume for the numerical results exactness, as regards the proportion of cases in which they respectively occur. The analysis, however, of my cases will doubtless lead to deductions far more reliable than impressions derived from a merely recollected experience, and still more reliable than the opinions which rest solely on either conjecture or a theoretical basis.

Naturally I am led to interrogate the cases first with reference to certain antecedent pulmonary affections, namely, pleurisy, pneumonia, bronchitis; and in this connection may be considered hæmoptysis.

Pleurisy is noted as having occurred prior to the development of the tuberculous affection in 22 cases. In determining the date of the tuberculous affection, the commencement of a persistent cough is taken as the criterion with respect to pleurisy, and also other antecedent diseases. Now, in determining the etiological influence of the pleurisy, the interval between the pleuritic disease and the commencement of the cough which denoted the tuberculous affection is, of course, an important consideration. It is to be added, that, in deciding that pleurisy had existed at some former period, it was necessary in most cases to judge from the statement of patients, together with such an account of the symptoms as could be obtained, and the appearance of the chest. In some of the cases evidence was obtained from a post-mortem examination; and in a few cases the pleurisy had occurred when the patients were under my observation.

The facts pertaining to the relation of pleurisy to the development of the tuberculous affection, in the 22 cases, are as follows: The tuberculous affection appeared to follow the pleurisy, either immediately or quickly, in 11 of the 22 cases, precisely one-half. In the remaining 11 cases, the pleurisy had preceded the persistent cough for periods varying from 4 years to several months. The interval was 4 years in one case only. It was 3 years in 3 cases. It was noted as "several years" in 1 case. It was 2 years in 2 cases. It was 1 year in 2 cases. It was noted as "several months" in 1 case; and in 1 case it is simply stated that two attacks of pleurisy had preceded the cough.

In 4 of the cases in which the persistent cough followed immediately, the pleurisy was attributed to an injury of the chest by a blow from the handle of a plough.

It is noted in six cases that the pleurisy was acute, and in seven cases the disease was chronic,—the notes being defective with reference to this point in the remaining cases.

We are certainly warranted by these facts in concluding that pulmonary tuberculosis is rarely preceded by pleurisy. Twenty-two instances make a small proportion out of several hundred cases. It is also a warrantable conclusion, that in some of these twenty-two cases there was no pathological connection between the pleurisy and the tuberculosis. Out of several hundred persons affected with any disease, or persons in good health, a certain proportion would be found to have had pleurisy within a period of four years. Some allowance is therefore to be made for mere coincidence. It is perhaps fair to conclude, that, of the eleven cases in which the persistent cough did not follow either immediately or quickly, the pleurisy, at least in several instances, had no etiological influence. On the other hand, excluding these eleven cases, in the remaining eleven cases in which a persistent cough did follow either immediately or quickly, a pathological connection is to be inferred. In a very small proportion of cases, therefore, pleurisy seems to stand in a causative relation to pulmonary tuberculosis, and yet there is room for the supposition that, in these cases, the causative relation is the reverse of this. The tubercles first formed may be seated at the superficies of the lung, and the pleurisy may be in consequence of their production. The pleuritic effusion having the effect of arresting for the time the progress of the tuberculous affection, the symptoms denoting the latter may not appear until after more or less absorption of effused liquid has taken place. This is, perhaps, the most rational view of the etiological relation between

pulmonary tuberculosis and pleurisy, when the latter is apparently an antecedent disease.

Pneumonia—meaning thereby the ordinary lobar form of pneumonic inflammation—is noted to have occurred, as an antecedent disease, in only nine cases. This very small number of cases is in striking contrast with an opinion which seems to be current with physicians, namely, that pulmonary tuberculosis is apt to originate in an attack of pneumonia. This opinion is certainly not sustained by clinical experience. Even in the nine cases in which pneumonia preceded, the interval between an apparent recovery from the pneumonic and the development of the tuberculous affection renders it probable, if not certain, that there was no pathological connection between the two diseases. In one case this interval was four years. In one case it was two years. In one case it was six months. In the remaining six cases the tuberculous affection appeared to follow either immediately or quickly the attack of pneumonia. Assuming that in these six cases, or even in all the nine cases, there was a causative relation, the result of this analysis certainly warrants the conclusion that the danger of acute lobar pneumonia being followed by tuberculous disease is extremely small.

This conclusion is corroborated by clinical experience from another standpoint, namely, an analysis of recorded cases of pneumonia with reference to the occurrence of pulmonary tuberculosis as a sequel. In 1861, I prepared a "Clinical Report on Pneumonia, based on an analysis of one hundred and three cases."* These cases I had recorded during the preceding twelve years. In not one of these cases was it noted that tuberculosis followed the pneumonia. It is true, that, in a considerable number of the cases which recovered, the patients passed from observation shortly after recovery; but had the pneumonia ended in tuberculous disease, the fact would surely have been embraced in the record, and so, also, if tuberculosis had been developed shortly after the termination of the pneumonia.

That pneumonia has little or no influence in the etiology, is further shown by a fact established by the numerical researches of Louis; namely, that when persons already tuberculous are attacked with pneumonia, the termination is generally in recovery. This fact was corroborated by my analysis. In seven of my cases, the patients affected with pneumonia were tuberculous; and in all these cases, save one case, recovery took place. In the excepted case the lungs were found, after death, crowned with miliary tubercles. It was a case of acute tuberculosis.

As with pneumonia, so with pleurisy; an analysis of cases of the latter disease sustains the conclusion to which I have been led respecting its influence in the etiology of pulmonary tuberculosis. An analytical study of recorded cases shows tuberculosis to be a rare sequel. In 1852, I prepared a "Clinical Report on Chronic Pleurisy, based on an analysis of forty-seven cases."† Of these forty-seven cases, in three the subsequent development of tuberculosis was probable, although not demonstrated; and in one case only the occurrence of this disease as a sequel was certain. Of fifty-three cases analyzed with reference to this point by Dr. Blakiston, not one became phthisical during the lapse of several years after recovery from the pleurisy.‡ The effect of chronic pleurisy with effusion, in a person already tuberculous, is, as is well known, to arrest for a time, or retard, the progress of the tuberculous disease.

I should add, in eight cases the histories showed that, immediately or shortly before the tuberculous disease, there had occurred some acute affection within the chest, the character of which was not determinable by the information obtained from the patients.

I come next to inquire respecting the occurrence of *bronchitis* as an antecedent disease. And, to avoid misapprehension, let me state that my inquiries will relate to bronchitis having the characters of a primary affection, namely, an inflammation of the bronchial mucous membrane, either acute or subacute, affecting the bronchial tubes about equally on both sides, that is, bilateral, extending more or less along the tubes, generally preceded by coryza, and not unfrequently by subacute laryngitis. As thus described, the affection embraces cases of so-called pulmonary or bronchial catarrh—a term which I cannot but regard as superfluous and objectionable. In popular parlance, the affection is known as a "cold in the chest." Now, do my cases show that this affection enters into the etiology of pulmonary tuberculosis?

Of 112 cases, the histories contain information bearing on the foregoing question. This information relates to the cough, as regards severity, and the absence of expectoration at first, and during a greater or less period. In only one case is it noted that, according to the patient's statement, there was expectoration with the commencement of cough. In one case there was no cough when the patient first came under my observation, the only ailment complained of being debility, while physical exploration gave unequivocal evidence of the tuberculous disease, which ended fatally. In only two cases is it noted that the patients were subject to frequent attacks of bronchitis, or, using their language, especially liable to "take cold," prior to the development of the tuberculous disease. In 72 of the cases, the cough was stated to have been at first, or for some time, without expectoration, that is, dry. In the great majority of the histories it is simply noted that, either at first or for some time, the cough was dry. In 39 of the 112 cases, nothing is noted with reference to this point. The duration of the dry cough was noted in 17 cases, as follows: Several months, 6 cases; eight months, 1 case; six months, 2 cases; four months, 2 cases; two months, 1 case; one month, 1 case; several weeks, 1 case; three weeks, 1 case; "a long time," 1 case, and a "considerable period," 1 case. In 74 of the cases the cough is noted to have been at first, or for some time, slight. The fact simply of the cough having been at first, or for some time, slight, is noted in 57 cases. In 17 cases, the length of time during which the cough was slight is noted as follows: "Several months," 5 cases; "several years," 1 case; "many months," 1 case; eight months, 1 case; six months, 1 case; four months, 1 case; three months, 1 case; one year, 2 cases; six weeks, 2 cases; one month, 1 case; and three weeks, 1 case. In 4 cases the cough was at first violent, in one of the cases being compared to whooping-cough; but in all these cases it was at first, and for some time, dry. In 34 of the 112 cases, nothing is noted respecting the cough being at first either slight or severe.

In a considerable number of my cases,—or, to be precise, in 39.—I have noted that the patients attributed the disease to "taking cold." In several of these cases the commencement of cough was dated from some particular exposure, such as being out of doors in inclement weather, or getting wet. It is needless to say, that statements in this regard have little or no value, since it is well known to be a popular notion

* Vide *American Journal of Medical Sciences*, Jan., 1861.
† Vide *Buffalo Medical Journal and Monthly Review*, Nov., 1852.
‡ Vide *Practical Observations on Certain Diseases of the Chest*. Republished by Lea and Blanchard in 1843.

that all affections of the chest, as well as a host of other affections, originate in a "cold." I presume no one will take exceptions to my considering the opinion of patients with reference to this point as of no weight in determining the existence of an antecedent bronchitis.

What is the conclusion to be drawn from the facts contained in my histories? Evidently, the conclusion is, they contain no evidence whatever that bronchitis has a causative influence in the development of pulmonary tuberculosis. With a single exception, in no instance do the characters of the cough, at its commencement, show that bronchitis existed as an antecedent affection. On the other hand, the histories, as regards the early pulmonary symptoms, go to show that they were incidental to the tuberculous disease. The evidence of this is in the slightness and the dryness of the cough at first and for some time, or, in not a few cases, for a considerable or a long period afterward. These facts are inconsistent with a primary bronchitis. If, as in the consideration of pleurisy and pneumonia, we take as a stand-point cases of bronchitis, either acute, subacute, or chronic, and inquire how often does pulmonary tuberculosis occur as a sequel, we must answer the question, not by figures, but by impressions founded on unrecorded experience. I cannot refer to a collection of recorded cases of bronchitis. But it is well known how common are cases of this affection. Now, I put this question to medical practitioners: Whenever you have no reason to doubt that a patient has only a bronchitis, either acute, subacute, or chronic, do you entertain apprehensions that this patient will become tuberculous as a consequence of the bronchitis? Taking statistical data embraced in the recorded histories of cases of bronchitis with reference to the occurrence of tuberculosis as a sequel, there is no alternative to this appeal to experience not based on the analysis of recorded cases. I think there is hardly room for doubt as to the answer to this question. Let a physician be satisfied that his patient has nothing more than a bronchitis, or a "common cold," and he feels no anxiety as to danger of consumption. Let it be decided that cough and expectoration, however protracted, be the symptoms of only a chronic bronchitis, and there may be danger of asthma and emphysema, but phthisis is not to be apprehended. I have, as I believe, in this way expressed the sentiments of the great majority of the experienced practitioners with whom it has been my fortune to be brought into professional relations.

The conclusion which I have drawn, from the analysis of my cases, respecting the etiological influence of bronchitis, is not in conformity with some late teachings by a German school, of which Niemeyer was the exponent. Niemeyer inculcated the doctrine that bronchitis not unfrequently leads to pulmonary consumption. He says: "A simple genuine catarrh may extend into the air-vesicles in a person of apparently perfect health and vigor," and "healthy men should never feel sure that they will not die of an acute or chronic catarrhal pneumonia (*i. e.* of phthisis) proceeding from a cold." Again, "Numerous examples exist in the practice of every experienced physician, in which the cough has commenced on some particular day following a severe cold, soon after which the other symptoms of consumption have made their appearance."* He inculcated this doctrine as having an important influence on the treatment of consumption. Indeed, he proposed as a name for the so-called tuberculous infiltration,—that is, the ordinary form of pulmonary tuberculosis,—"chronic catarrhal pneumonia," with express reference, as he stated, to the influence on measures of prophylaxis and therapeusis.

I shall not here discuss this doctrine on the ground of its inconsistency with well-known pathological facts, such as the frequency of bronchitis in childhood and in old age, periods of life when the development of phthisis is relatively rare; the fact that for bronchitis to extend into the bronchioles it must be of the variety known as capillary, and this variety is exceedingly rare during the period of life when phthisis is most apt to occur; the improbability of bronchitis, which is a bilateral affection, giving rise to the "catarrhal pneumonia," *i. e.*, infiltrated tubercle, on one side only, for a considerable period before the affection occurs on the other side; and, finally, regarding the tuberculous infiltration as a variety of chronic pneumonia, the fact that a bronchitis, however acute, and even when it affects the smaller tubes, has no tendency to give rise to an acute pneumonia. Waiving a discussion into which these and other facts would enter, I will simply raise the inquiry, How is the doctrine that pulmonary consumption, as stated by Niemeyer in another quotation, "arises, with rare exceptions, through extension of a chronic catarrh into the finer terminal bronchioles, and thence into the pulmonary vesicles," to be either proved or disproved? The answer to this question is plain. The doctrine is to be either proved or disproved by direct clinical observation; that is, determining, by an analysis of a sufficient number of recorded cases, whether pulmonary tuberculosis often, or rarely, commences with, or is preceded by, bronchitis. Niemeyer did not claim to have himself studied cases in this way, nor did he base the doctrine on the studies of others. His assertions, therefore, dogmatic as they are, have only the value of an opinion resting on conjecture or on theoretical reasoning.

I should have more reserve, perhaps, in referring thus to Niemeyer, if my own clinical studies in relation to the causative influence of bronchitis stood alone. It is now nearly fifty years since the publication of Louis' Researches on Phthisis.* He studied eighty carefully recorded cases with reference to antecedent affections. His conclusion was, that "pulmonary catarrh," *i. e.*, bronchitis, as also pneumonia and pleurisy, rarely, if ever, entered into the etiology of phthisis.

The great man just named has but recently been called to the sphere which lies beyond our present life. His work on phthisis, was, I believe, the first which exemplified the numerical method of investigation, of which he was the founder. Then followed his great work on the typhoid affection. No stronger evidence of the value of the method of study which he inculcated and practised can be adduced than this: nearly all his conclusions have been confirmed by the researches of others who have repeated his labors; and, remaining to-day more firmly established than at first, they will so continue forever, unless, with the lapse of time, diseases undergo material changes. This is not an occasion to pronounce a panegyric upon his life and labors. Let me add, that were this to be done on a fitting occasion, by a competent eulogist, it would not only be an act of justice in honor of the memory of one, than whom few have rendered to medicine greater service, but it would be useful by inciting enthusiastic minds to follow his example, and

* *Text-book of Practical Medicine*, seventh edition. Translat on by Drs. Humphreys and Hackley.

* *Recherches Anatomico Pathologiques sur la Phthisie* Par Ch. A. Louis. Paris, 1825.

engage in the method of study which he inaugurated.

As an antecedent event, hæmoptysis is now to be studied.

This event occurred prior to the commencement of a persistent cough in fifty-six cases. In eighteen cases persistent cough, with other evidence of the existence of tuberculous disease, followed immediately a hæmoptysis. In thirty-seven cases hæmoptysis occurred once or repeatedly, cough and other evidence of tuberculous disease following after an interval of greater or less length. The length of the interval varied much in the different cases.

It is noted in one case to have been sixteen years; in one case fifteen, and again four years; in one case ten years; in one case six years; in one case four years, and, in this case, there were several recurrences of the hemorrhage; in two cases three years, in one of which repeated attacks occurred; in one case two years, and there were three successive attacks; in two cases two years; in two cases one year; in five cases several months; in one case six months; in two cases four months; in one case two months; in one case eight months; in one case five attacks during three months, persistent cough following the last attack; in two cases two attacks with an interval of a month between the two, and persistent cough following the last attack. In the remainder of the cases the interval is not specified. In sixteen cases it is noted that the hæmoptysis occurred when the person affected appeared to be in perfect health. In a few cases the hæmoptysis followed some unusual muscular exertion; but, in most of the cases, no apparent exciting cause of the hemorrhage is noted.

It is noteworthy that the development of pulmonary tuberculosis was preceded by hæmoptysis in such a considerable number of cases. The number of cases in which pulmonary tuberculosis became developed many months and years after the occurrence of hæmoptysis, is also worthy of note. In this latter point of view, the facts go to show that hæmoptysis is to be considered a forerunner of phthisis, albeit the tuberculous affection may be long delayed. Ware's valuable analysis of 386 cases of hæmoptysis, noted in private practice during a period of about forty years, showed that in sixty-two cases the patients were afterward known either to be living in ordinary health, or to have died of other diseases having no connection with the existence of tubercles, the length of time during which this immunity continued varying from two to thirty-seven years.* Doubtless in more or less of these cases, tuberculosis existed when the hæmoptysis occurred, the patients recovering from the tuberculous affection. Of the cases in which tuberculosis did not coexist, judging from the facts developed by my analysis, it is probable that some became tuberculous after the date of the analysis of the cases, and also that tuberculous disease would have probably occurred in some of the cases had not the persons been taken off by other diseases. Moreover, the hæmoptysis may in some of the cases have denoted a tendency to tuberculous disease which, from age or the operation of prophylactic influences, did not become developed.

One conclusion, then, to be drawn from the results of my analysis is, that, whenever hæmoptysis is not evidence of an existing tuberculous affection, it has significance as a prodromic event. Another conclusion is, that hæmoptysis is not a cause of phthisis, as was asserted by Niemeyer. This is a fair inference from the fact, that in only about one-third of the cases in which hæmoptysis occurred as an antecedent event, was it immediately followed by the evidence of tuberculous disease, an interval of weeks, months, or years elapsing in two-thirds of the cases.

Regarded in the light of a prodromic event, hæmoptysis has of course some pathological connection with the development of tuberculous disease. The nature of the pathological connection, our present knowledge does not enable us to understand. It is not an inconsistent, if, indeed, it be not a rational supposition, that, in certain cases, the occurrence of bronchial hemorrhage, so far from being a cause of, is a substitute for, the local processes involved in the production of tuberculous disease. This supposition is in harmony with a fact which Ware's statistics established, namely, that hæmoptysis, occurring *after* the development of tuberculous disease, is of favorable import, as regards either the arrest or the retardation of the progress of the tuberculous disease.

With regard to antecedent diseases other than those affecting the pulmonary organs, an analysis of my cases furnishes the following facts:—

Intermittent fever is noted in twenty-five cases, exclusive of those in which it is not certain whether the paroxysms were malarial or incidental to the tuberculous affection. In seven cases the tuberculous affection is noted to have become developed immediately after an attack of intermittent fever. In four cases the symptoms of the tuberculous affection occurred during the continuance of intermittent fever. In five cases it is noted that the tuberculous affection followed soon after intermittent fever; and in four cases it is simply noted that intermittent fever preceded the tuberculous affection. In these twenty cases, the two diseases were in close chronological connection. Of the remaining five cases, it is noted in one case that intermittent fever preceded with an interval of several months; and in one case, simply that the patient was subject to intermittent fever. In three cases, intermittent fever had occurred frequently during, in one case, the preceding year, in one case the preceding five months, and in one case the preceding three months. These facts do not go to support an opinion heretofore held by some, that malarial toxæmia affords a security against tuberculous disease.

Measles is noted as an antecedent disease in six cases. In two of these cases, persistent cough dated from the attack of measles; in one case six months, in one case one month, and in one case five years elapsed between the measles and the development of the tuberculous affection.

Dyspepsia is noted in five cases. In one case it had existed for fifteen years; in one case for several years; in one case for a year; in one case for several months; and in one case its duration is not noted.

Diarrhœa is noted in three cases. It had existed in one case for four months; in one case for a month; and in one case the duration is not noted.

In three cases the patients were subject to attacks of rheumatism; and in one case the tuberculous disease immediately followed rheumatism which had existed for three months.

Perineal fistula preceded the pulmonary disease in four cases. In one of these cases the fistula had been nearly cured nine months before the first symptoms of tuberculosis of the lungs. In one case it preceded a second occurrence of pulmonary tuberculosis, the patient having, apparently, recovered from phthisis four years previously. In one case an operation had been performed for the cure, but without any success. In the remaining case the fistula occurred a year before

* *On Hæmoptysis as a Symptom*, by John Ware, M.D., etc. Publications of the Massachusetts Medical Society, 1860.

the development of tuberculous disease of the lungs, and was cured by a surgical operation.

A scrofulous affection of the glands of the neck was noted in three cases. In one of these cases the cervical glands had been swollen two years before the development of the pulmonary tuberculosis. In another case, suppuration of these glands had taken place a year previously, and there were present the characteristic cicatrices, the age of the patient being 24. In the remaining case there had been suppuration of these glands, leaving characteristic cicatrices, when the patient was 14 years of age; the age when the case came under observation with pulmonary tuberculosis being 34 years.

In five cases it is noted that the patients had had syphilis; but it is quite certain that in many, if not most of the cases, inquiries were not directed to this point.

In one case bronchocele had existed, and a cure was effected by iodine, a year before the occurrence of phthisis.

One patient had been affected for a long time with psoriasis.

One patient had had parotiditis shortly before the development of the tuberculous disease.

In one case the tuberculous disease followed shortly after recovery from small-pox; in two cases shortly after typhoid fever; and in one case, shortly after yellow fever.

In four cases it is noted that the health was impaired prior to the tuberculous affection, but without any well-defined disease.

In one case dysentery preceded, for a short period, the tuberculous affection.

One patient had had urinary calculi.

In one case there had been three operations for the removal of recurring fibroid tumor of the neck.

In one case the tuberculous affection was preceded by suppurative inflammation of the ankle, and also disease of the hip.

In one case the affection was developed in a patient with diabetes mellitus; and in one case in a patient with Addison's disease.

To extend the analysis to other points would be, perhaps, to presume too much upon the attention of my auditory; and in bringing this paper to a close, I submit a series of propositions embracing a recapitulation of certain facts, together with some deductions relating to the etiology of pulmonary tuberculosis.

1. The results of my analysis show that the varied occupations of life favor the production of the disease in so far as they involve confinement within doors and sedentary habits. My collection of cases contains no evidence of the etiological agency of the inhalation of dust, particles of stone, of metal, or any matter giving rise to local irritation; on the contrary, there is a remarkable absence of occupations involving exposure to irritating inhalations. The number of occupations represented by only two, three, or four cases, and by a single case, affords evidence that an etiological agency derived from this source relates exclusively to sedentary habits and confinement within doors.

2. Inflammatory affections within the chest, namely, pleurisy, pneumonia, and bronchitis, have very little if any causative influence in the development of the disease.

3. Hæmoptysis, when it is not a symptom of existing pulmonary tuberculosis, should be considered as having the significance of a prodromic event; but there is no clinical evidence of its standing in a direct causative relation to the disease.

4. The absence, in my collection, of any cases in which asthma, emphysema, and organic affections of the heart were antecedent affections, may be noticed as sustaining the opinion that these affections are antagonistic to the liability to pulmonary tuberculosis. Here I refer to "negative facts," and they are subject to the qualification stated at the beginning of this paper; but it is certain that, in the considerable number of cases in which the previous health was noted, if these affections had existed, their existence would have entered into the records.

5. Of the antecedent "general diseases," the number of instances in which intermittent fever had existed might perhaps lead to the conclusion that malaria is to be reckoned among the causes of pulmonary tuberculosis. But when it is considered that nearly all my cases were observed in sections of country more or less malarious, a large allowance is to be made for mere coincidence. Hence, that malaria does not protect against tuberculous disease, is the only deduction admissible.

With regard to other essential fevers, namely, measles, small-pox, typhoid fever, and yellow fever, the number of cases in which these diseases existed antecedently is so small as to afford little, if any, evidence of an etiological influence referable to them.

6. My cases afford no evidence that scrofula (meaning by this term an affection, a distinctive feature of which is enlargement and suppuration of the cervical glands, leaving characteristic cicatrices) enters into the etiology of pulmonary tuberculosis.

7. The results of my analysis go to show that, aside from the diseases named in the foregoing propositions, there are none which are to be considered as involving a special tendency to the subsequent development of pulmonary tuberculosis. Twelve additional diseases only appear in my records. Of these twelve diseases, eight are severally represented by a single case. Those which are represented by more than one case are dyspepsia, perineal fistula, syphilis, and rheumatism. The number of cases representing these four diseases is altogether too small to give evidence of a causative relation. There is no evidence, derived from my analysis, to sustain the hypothesis of Niemeyer, which attributes the production of miliary tubercles to the absorption of morbid products in different parts of the body.

In conclusion, the result of my analysis, in so far as it has extended, sustains the doctrine that pulmonary tuberculosis is eminently a diathetic disease; that is, it arises from an internal or constitutional determining agency which it has been customary to designate a diathesis. Assuming this to be a correct conclusion, it would be unprofitable to speculate concerning the essential nature of the diathetic condition. Taking, however, this conclusion as a point of departure, it remains to determine, by clinical studies, the causes of the tuberculous diathesis. As regards this object, there are various points of inquiry, prominent among which are questions concerning habits of life, congenital disposition, hereditary influence, and, perhaps, contagion. I reserve an analysis of my cases with reference to these and other points for some future occasion.

Through an unintentional error, my paper was announced in the printed notices, as a "Contribution to the Pathology of Tubercle." Etiology is, indeed, a department of pathology; but, more than this, etiological doctrines must, almost of necessity, affect those which pertain to the pathological character of diseases. At this moment there is a conflict of opinions re-

specting the doctrine just stated. That pulmonary tuberculosis involves a special diathesis, innate or acquired, has been until quite recently the prevailing opinion. The tendency of the so-called "new views of tuberculous disease," emanating from our German brethren, is to depreciate the diathetic character of this disease. According to these views, the development of pulmonary tuberculosis is due largely, or chiefly, to extrinsic causes acting directly upon the lungs, or to morbid conditions seated in these organs. This conflict of opinions is not merely one of pathological interest; the question is one fraught with practical consequences. Our rational views respecting the prophylaxis and the treatment of pulmonary tuberculosis cannot but be affected in no small measure by the degree of importance which we attach to its diathetic character. The pathological question is one which concerns the practice as much as the principles of medicine. Giving due weight to this consideration, let us not permit our minds to be unduly biased, on the one hand, by an obstinate determination to adhere to a doctrine because we may have already adopted it, nor, on the other hand, by the attractiveness of novelty, or a feeling that what is new necessarily denotes actual progress in knowledge. The truly philosophical course evidently is to consider well the means of investigation by which the question is to be settled, and to aim at a correct conclusion without regard to either past or present opinons.

A CASE OF LONGITUDINAL FRACTURE OF PATELLA.

By C. T. POORE, M.D.,

NEW YORK.

M. L———, an actress, about 25 years of age, while attempting to spring from a bar, twenty feet from the stage of a theatre, fell, and a net which was arranged to catch her in such a case partially broke her fall, but her right leg was thrown violently out on the stage. She finished her acting, which called for considerable muscular effort, and was able to walk home, a distance of half a mile, although suffering considerable pain.

The next day she was able to limp about the house. Her physician saw her, but could detect scarcely any swelling or pain about the knee-joint, but she complained of some pain, and a grating sensation, when she attempted to flex her knee in walking. There was a contused wound over the upper border of the right patella, just on the inner side of its median line, as though it had struck on some blunt object.

I saw her, in consultation, three days after the injury. Patient limped into the room, and said she did not suffer much pain, except on bending the knee.

On inspection, there was no difference between the right and left knee, either in color or in size. Careful examination failed to detect any heat or tenderness about the joint. She complained of considerable pain on pressure over the outer half of the patella, as though it had been bruised. On grasping the bone, and moving it laterally, but little pain was felt, and no crepitus could be detected, nor was there any unevenness of surface. On grasping the outer portion of the bone with one hand, and the inner with the other, and making alternate motion, in a longitudinal direction, distinct crepitus could be felt and heard, and on depressing either side of the bone a slight fissure could be felt, running from a point just outside of its middle, on its upper border, downwards, and slightly inwards to its lower and inner border. When the leg was extended she complained of no pain, but flexion of the leg on the thigh gave distress. There was evidently a longitudinal fracture of the right patella, without any laceration of its fibrous covering, and without any injury to the knee-joint. Not having had charge of the case, I am unable to give the result, but her physician informs me that she has good use of the limb.

Vertical fracture of the patella is a rare injury, if we may judge from the literature of injuries to that bone.

Hamilton,* in his work on Fracture and Dislocations, mentions the fact that longitudinal fractures have occurred, but has never seen one, nor does he mention any case. Lonsdale mentions having seen a case of this fracture, but gives no particulars. He also refers to four specimens in the Museum of Middlesex Hospital; in two of these there was bony, and in two ligamentous union.

Sir Astley Cooper records two cases of this fracture. In one of these a quarter, and in the other a third, of the patella was broken off. In one case there was no attempt at union; the other was united by ligament. He also found a longitudinal fracture of both patellæ in a subject in the dissecting-room of St. Thomas' Hospital, and although the fragments were in contact, they were only united by ligament.†

Dupuytren mentions five cases of vertical fracture of the patella; four were caused by a fall from a height, and one from being run over by a wheel. In one case the bone was divided into two equal parts; in three the fracture was not in the median line of the bone, and one was fractured diagonally. In two cases there was no separation of the fragments; three were united by callus, two proved fatal on the twentieth day after the injury, one on the third day, the other from other causes.‡

FIBROID TUMOR OF THE UTERUS ABSORBED DURING PREGNANCY.

By R. C. M. PAGE, M.D.,

NEW YORK.

Mrs. P———, æt. 26 years, a housekeeper by occupation, and married for seven years. She first menstruated at the age of fifteen, and was quite regular in time and quantity, the flow lasting about four days, and free, though moderate in quantity, without pain, until about one year after marriage, at which time it disappeared for eight weeks, when suddenly, and without any apparent cause, it came on profusely, and lasted for thirteen weeks altogether. After that the flow recurred every two weeks, and would last for eight or ten days, being at the same time quite profuse, and ending in an abundant hemorrhage. About the month of March, 1872, she began to enlarge about the abdomen. This condition continuing, she applied to me, while House Surgeon of the Woman's Hospital, for admittance to that Institution on the 19th December, 1870. She was, at that time, examined by myself and Dr. Thomas Addis Emmet, the surgeon-in-chief of the Hospital, but had to be sent home, as there was no vacancy at the time. The anterior wall and fundus of uterus was found to be very much thickened, and the organ extending up as far as the umbilicus. The uterine cavity measured six and a half inches in depth, and the os patulous. She suffered no pain or other trouble, but was very anæmic, and she had now more or less

* Fract. and Dislocations, London, 1868.
† Cooper on Fracture and Dislocations, Boston, 1825.
‡ Dupuytren, translated by Doane, New York, 1823.

flow of blood all the time. Auscultation revealed a bellows murmur at the base of the heart, with the second sound, which proved to be due to her anæmic condition. As the patient was very poor, and did not live far from the Hospital, I was requested by the surgeon-in-chief to attend her at her home, with a view to getting her into the Hospital should a vacancy occur in the free ward. I accordingly visited her, and by means of tr. iodine applied to the *fundus uteri* occasionally, together with the tampon, I checked the menorrhagia, and in a few months succeeded in restoring the menstrual function to its normal condition. She was also put upon iron, and in six months the cardiac murmur disappeared also. After leaving the Hospital, my term of service having expired in April, 1871, the patient continued under my care. She came to my office twice every week to have applications of carbolic acid and glycerine, equal parts, applied to the *fundus uteri* in order to check the leucorrhœa which she had, and to guard against a return of the menorrhagia. The following June, however, as she appeared to be so well, I discharged her, with the advice to notify me at once should hemorrhage recur. The latter part of July she had her period as usual, but, much to her surprise and uneasiness of mind, it did not return in August; in short, it soon became evident that she was pregnant. In the early part of May, 1872, she was delivered of a fine boy without any difficulty. In July last I examined her, with Dr. J. H. Ripley, and we found the uterine cavity measuring *two and a half inches in depth*. The abdomen, which at the examination by myself and Dr. Emmet, in December, 1870, was *flat* upon percussion as far up as the umbilicus, was now *tympanitic*, and by bimanual manipulation the uterus could only be felt behind the symphysis pubis by firm pressure, as in any case where the uterus is of normal size. No fibroid tumor of the uterus therefore now existed, for the organ appeared to be of normal size by every method of examination. The conclusion arrived at, therefore, was that the large fibroid tumor, *which existed beyond a doubt before*, had, *during pregnancy, been absorbed by pressure of the fœtus*, and been *entirely removed* in the retrograde development of the uterus. The patient is now (January 3d, 1873) in excellent health and condition, having recently recovered from the operation for *fistula in ano*, which I performed early last month.

No. 65 West Thirty-sixth St., New York City.

Progress of Medical Science.

Ovariotomy by Enucleation.—Dr. J. F. Miner, Surgeon to the Buffalo Gen'l Hosp'l (*Am. Jour. Med. Sciences*), publishes more cases of ovariotomy by enucleation, without clamp, ligature, or cautery, and believes that all ovarian tumors capable of removal can and should be removed by the method proposed, with advantages so manifestly superior as to commend it for trial before resorting to any other plan.

Impacted Fracture of Neck of Femur.—Dr. McGraw (*Michigan University Medical Journal*), at the last meeting of the Michigan State Medical Society, presented a specimen of impacted fracture of the neck of the femur, removed thirty-eight years after its occurrence. The patient, now 54 years of age, was injured by a bank of earth falling upon him when 16 years old. Though he acquired full and complete use of both limbs, the effects of the injury had always remained visible in a marked eversion of the left foot and a slight eversion of the right one. On account of obstinate recurrent sarcoma of the thigh, amputation at the hip-joint was recently and successfully performed. The patient made a good recovery. One of the interesting features of the case was the opportunity it afforded of examining a specimen of impacted fracture thirty-eight years after its occurrence. The head of the bone was evidently thrust down between the trochanters, so that the great trochanter rose above it. It was also twisted so that a portion of the neck was brought to bear against the edge of the socket. This stimulated a new growth of bone, so that the head, as it appeared in the specimen, was very much elongated and enlarged. The acetabulum was altered in shape to correspond. The femur was slightly everted.

Pneumothorax.—D. T. Gilliam, M.D., Nelsonville, Ohio, (*Clinic*, Sept. 28, 1872), records a case of this infrequent affection, without pleuritis, ending in recovery. He rejects the opinion that metallic tinkling arises from drops of fluid falling into a liquid contained in a cavity. 1st. Because he cannot conceive of a circumstance so fortuitous, occurring with so much regularity and definite exactness, as in this case. 2d. Because the character of the sound, after the first day, could by no stretch of the imagination be made to resemble the sound produced by the dripping of one fluid into another. 3d. Because he was satisfied that the pleural cavity contained no fluid, and hence the phenomena could not be produced by a cause that did not exist. The sound presented in its greatest intensity, and was referable to a point corresponding to the spot where the patient experienced the most pain.

Retroversion of the Unimpregnated Womb.—A. Reeves Jackson, M.D., Surgeon-in-Chief of the Woman's Hospital, State of Illinois (*Chicago Med. Journal*, Oct. 1872), in a paper read before the Chicago Society of Physicians and Surgeons, on this subject, thus summarizes: 1st. Chronic retroversion of the womb, unaccompanied by structural disease, is of rare occurrence, and may be regarded as a harmless disorder. 2d. The distressing symptoms usually attributed to retroversion are dependent upon complications involving structural change, as engorgement, inflammation, retroflexion, etc., rather than upon the displacement itself. 3d. These complications are to be regarded as primary in point of time, as they are in pathological importance. 4th. The treatment should have reference, first, to the removal of the structural lesion; and secondly, to the replacement of the organ and its retention by appropriate means. He would suggest that the best time for replacing the organ, after the tenderness and heaviness have been sufficiently reduced, is just prior to a menstrual period. If the operation be carefully performed, and great caution exercised during the time of flow, it will occasionally be followed by permanent relief. The catamenial period determines a reparation and renewal of uterine tissue which supply a valuable aid in the treatment of most of the disorders of the organ.

Amputation of the Knee-Joint.—Henry Gibbons, Jr., M.D., San Francisco, Cal., (*Pacific Med. and Sur. Jour.*, Sept. '72), reports a case of successful knee-joint amputation, in a lady forty-six years of age, who had long suffered from tuberculosis of the left ankle-joint. The leg was first amputated in the lower part of the middle third, by the circular method. After many discouraging attempts were made to accomplish a cure, the patient submitted cheerfully, months after the first operation, to the latter amputation. Forty-

six days after the operation the wound was entirely well. On examination a good stump was disclosed. The patella fitted in nicely between the condyles, and made a finely rounded end, in nowise intolerant of pressure, while the cicatrix being on the posterior surface, and from two to three inches above the extremity, was entirely removed from the effects of chafing or pressure.

He calls attention to the excellent tables of cases collected by Drs. Bruton and Markoe, with the results.

Hay Fever.—Morrill Wyman, M.D., in his work on "Autumnal Catarrh (Hay Fever)," advocates in the asthmatic stage, the smoking of stramonium, also the espic cigarette. The composition of each cigarette is as follows:

℞ Belladonna leaves, 4½ grs.; hyoscyamus, 2¼ grs.; stramonium, 2¼ grs.; phellandrium aquaticum leaves, ¾ grs.; opium, ½ grs.

Relation of Hæmoptysis to Pulmonary Consumption.—In a translation by Hamilton Osgood, M.D., of a portion of Niemeyer's monograph on "The Relation of Hæmoptysis to Pulmonary Consumption," written about fifteen months previous to his death (*Phil. Med. Times*, October 19, 1872), the author defines his views concerning the relation of capillary, bronchial, and pulmonary hæmorrhage to consumption of the lungs, in the subjoined propositions: 1st. By no means all individuals who suffer from capillary, bronchial and pulmonary hemorrhage are, or become, consumptive. 2d. Not unfrequently, consumption of the lungs follows capillary hemorrhage of the lungs and bronchia, without the existence of a genetic connection between the hemorrhage and the pneumonic processes which, as a rule, form the origin of the phthisis. The same individuals who are predisposed to these hemorrhages, are also disposed to the inflammatory processes. 3d. Capillary, bronchial and pulmonary hæmorrhages frequently lay the foundation of phthisis in persons in whose lungs neither tubercle nor pneumonic products exist; and the reason for this is, that the blood which is retained in the alveoli of the lungs, and the inflammatory products which are called forth by the same, undergo cheesy metamorphosis. 4th. In the same manner, bronchial and pulmonary hemorrhages not rarely hasten the course of an already existing phthisis. 5th. In individual and rare cases, hæmoptysis is not the cause, but the *consequence*, of pneumonic processes, which in their protracted course lead to pulmonary consumption. Such cases are easy of recognition, because commonly severe fever and other indications of inflammation accompany or precede the hæmoptysis. 6th. The blood which remains in the alveoli, and which, together with the pneumonic infiltration, has become cheesy, sometimes causes an eruption of miliary tubercle.

Destruction of the Kidney by Suppuration.—A. Fisher, M.D., Chicago, Ill. (*Chicago Med. Examiner*, October 1, 1872), relates a case of destruction of the kidney by suppuration, the patient being a male, aged 47 years, who, during the past sixteen years, has had frequent attacks of pain in the left kidney, with difficulty in urinating. The history of this case shows that suppuration of one kidney may be so chronic and insidious in its progress, that the ordinary symptoms which characterize an abscess of that organ may be entirely wanting. It also proves that a person can live with one sound kidney; for after the abscess was opened, he improved steadily until it opened into the thoracic cavity from the external opening. After that occurrence he sank rapidly, and died in two or three days.

Fracture of Skull, etc.—J. F. Fitzpatrick, M.D., Civil Surgeon, Kurnool, India (*Madras Med. Jour.*, Jan., 1872), relates the following case, with explanatory cuts:—A police head-constable was savagely attacked by a brother policeman with a heavy native tulwar, with these results: Right side of head and ear severely hacked, there being numerous cuts three to four inches long; parietal bone fractured immediately behind its articulation with the frontal, the fracture extending from the anterior inferior angle, upwards, about three inches, the anterior edge being depressed exactly to the extent of the thickness of the posterior, from which latter two or three fissures passed backwards about one inch. The left eye completely destroyed by a cut which fractured the external angle of orbit. Right shoulder-joint laid open by one clean sweeping cut, commencing beneath the acromial process, dividing all the structures in front and outer side, opening the joint, leaving the vessels and nerves of axilla intact. Index and middle finger of right hand separated at their metacarpal extremities, and the thumb at the first phalangeal articulation, etc.

When reaction had set in, about thirty-six hours after admission, the head of the humerus was freed from its few remaining attachments, turned out, and sawn off immediately below the tuberosities. No vessels were divided. Two pieces of parietal bone were removed when completely loosened. In reviewing this case he was naturally surprised at the miraculous escape: 1st, from the extent of fracture of the skull and its seat over middle meningeal artery, without laceration of the coats of the vessel; 2d, that the arm was almost severed at the shoulder-joint, yet the vessels and nerves of axilla were not divided; 3d, that the ribs could get completely cut through without penetration and injury to internal viscera. Such a combination of serious and aggravated wounds occurring without a fatal termination is, he thinks, seldom seen; yet here is one in which there is perfect recovery, perfect as far as nature and art could possibly accomplish after the mutilation received. A wound laying the shoulder-joint so completely open, and giving an opportunity of practising the conservative power of resection over amputation for primary injury (other than gunshot wounds), is not of frequent occurrence. The treatment of the other injuries was simply on the expectant principle, removing all sources of irritation that might thwart or interfere with the natural curative process.

Veratrum Viride in Pulmonary Hemorrhage.—H. N. Eastman, M.D., of Geneva, New York. (*Buffalo Med. and Surg. Jour.*, employs veratrum viride in pulmonary hemorrhage, when no acceleration of the heart's action is present, for the express purpose of reducing the normal circulation to the lowest point compatible with the safety of the patient, and to distend the pulmonary vessels as little as possible with the incoming blood. The idea is that such prevents farther rupture of the capillaries of the part, and affords an opportunity for the vascular lesions already existing to be obviated, by temporarily reducing the normal circulation.

Glycerine Ointment.—Prof. Chas. A. Joy (*Jour. Applied Chemistry*) gives the following formula for a glycerine ointment, useful in chapped hands and excoriations:—One-half ounce of spermaceti is melted together with a drachm of white wax and two fluid ounces of oil of almonds, by a moderate heat; the mixture is poured into a mortar, when a fluid ounce of glycerine is added to it and rubbed till the ingredients are thoroughly mixed and cold.

Chiccory in Incontinence.—J. H. Thompson, M.D., of Goshen, N. Y. (*Med. and Surg. Reporter*, Sept. 21, 1872), writes that, from observation and experience in the administration of chiccory, he is satisfied that it is a valuable agent in incontinence, the result of atony and relaxation of the sphincter and other muscles.

His knowledge of its efficacy was derived by the accident of observing, in the case of an individual afflicted with incontinence, that the difficulty was markedly alleviated when he used *mixed* coffee, and, *vice versa*, was aggravated when *pure* Java coffee was used as the beverage. Subsequent experience confirms his belief in the efficacy of this agent. He has prescribed to elderly patients, with advantage, a decoction of pure chiccory. He has not had an opportunity of prescribing this remedy in the cases of children.

Diagnostic Symptom in Cerebro-Spinal Meningitis and Myelitis.—Dr. John Brownrigg, of Columbus, Miss. (*Med. and Surg. Rep.*), speaks of a peculiar form of ophthalmia as a diagnostic symptom in cerebro-spinal meningitis and myelitis:—

This form of ophthalmia comes on about the third or fourth day. First one eye is inflamed, while the arm and leg of the opposite side is convulsed. It becomes most marked when paralysis results in the opposite side, indicating the development of myelitis. Then the other eye becomes inflamed, while the opposite side is convulsed, to be paralyzed in its turn. The disease follows this course most frequently in children.

The conjunctiva is first slightly injected, the color gradually deepening until it assumes a peculiar pink shade. At first there is secreted from the conjunctiva a flaky white pus, gradually becoming more fluid, but always very white. The eyeball gradually sinks deep into its socket and becomes flattened. This symptom has often enabled him to distinguish this disease, when in danger of mistaking it for convulsions from other causes, especially in children, when the case has not been under observation in its early stages. The inflammation may be attributable to an extension of the inflammation from the brain along the optic nerve.

Induction of Premature Labor.—It is now 116 years ago since a consultation of physicians was held in London to consider the propriety of inducing labor in certain cases; and Dr. Macauley was the first, in 1756, to perform the operation after the London meeting, by rupturing the membranes.

To show with what ease premature labor can be induced by the placing of a flexible bougie in the uterus, as recommended by late authors, a case is related by Dr. J. C. McMechan, of Cincinnati, O., in the *Med. and Surg. Reporter*, Sept. 14, 1872.

A New Rule for Doses.—E. H. Clarke, M.D., Boston, Mass. (*Boston Med. and Surg. Jour.*), would have the doses of most medicines increased or diminished in the proportion of the weight of the patient to that of number of pounds. This proportion is represented by a fraction whose numerator is the patient's weight and whose denominator is 150. If a child at birth weighs six pounds, the appropriate dose for it would be 6-150 or 1-25; if it weighs ten pounds, 10-150 or 1-15. A child two years old, weighing twenty pounds, would require 20-150 or about 1-7 of an adult dose; or, more precisely, 1-7½, which is exactly half way between the quantity indicated by the table of Gaubius for a child two years old and that indicated by Dr. Young's scheme for the same age. A person whose weight is two hundred pounds should have 200-150 or 1 1-3 of an average adult dose. A child twelve years old, weighing 75 pounds, would require 75-150 or 1-2 of an average dose. The modifications of the average dose, demanded by a patient's idiosyncrasy, disease, and other conditions than age or weight, are not, of course, met by the above rule.

Myocarditis and Endocarditis in Cases of Diphtheria, Croup, and Membraneous Angina.—In a lecture recently delivered at the *Hôpital des Enfants*, Dr. Bouchut laid stress on the frequency of disease of the heart in cases of diphtheria, and other septic diseases. The endocarditis, he said, was valvular and parietal, of a proliferating character, and was accompanied by fibrinous deposits on the diseased walls, and of large ventricular clots. The fibrinous deposits adhering to the diseased valves may become loose, and be carried away by the blood into the aorta or preliminary artery, and then give rise to embolisms.

Croup.—Dr. Robert Jordan, of Birmingham, does not believe that the majority of cases of croup have no false membrane, but are essentially inflammations of the mucous membrane of the larynx and trachea, accompanied by secretion of tenacious mucus, and also considerable swelling caused by considerable swelling into their sub-mucous areolar tissue; in other words, they are catarrhal inflammations of the larynx and trachea. When exudation is really present, it is a case of diphtheria.—*Med. Times and Gazette.*

Ingrowing Toe-Nail.—Mr. Blower cures ingrowing toe-nail by first destroying with nitric acid any granulations that may be present, and then introducing beneath the nail a piece of firmly compressed sponge, of a size something less than a grain of rice. The piece being retained in place with strips of adhesive plaster, applied longitudinally in order to avoid compression; the swelling of the sponge by imbibition causes the nail to be separated from the irritated flesh.—*Br. Medical Journal.*

Feeding by the Nose in Attempted Suicide by Starvation.—Dr. Anderson Moxey calls attention to the advantages of this method of feeding insane and other patients who decline to take food of themselves. The stomach-pump he condemns as the most unmerciful engine that has ever been used for this purpose. The mode of conducting the process of feeding is first to see that the patient has no weapon of offence, then to handcuff him, place him in a strait-waistcoat, or otherwise control his movements. Three attendants (or more if required) should firmly, but without violence, lay the patient on his or her back, on a bed, the pillows being removed. The patient's head should be received between the knees of the surgeon, the chin then slightly elevated, and a smooth Wedgewood funnel introduced within, only within, one of the nostrils, where it is to be held lightly and without pressure during the entire administration, it being borne in mind that it is simply used as a convenient medium for supplying the food to the nostril. Through the funnel thus held any fluid or semi-solid nutriment may then be poured from a jug, taking care that it is done slowly and with occasional pauses, that the patient may take breath; for the reflex acts of deglutition, infallibly excited and vainly resisted, which follows the transmission of liquids through the noses into the pharynx, follow one another so fast that a rest now and then is necessary.

Care should subsequently be taken that the patient does not have the use of his hands to produce vomiting by irritating the fauces.

The operation should be repeated every four hours, until the patient is willing to feed himself.—*The Lancet.*

THERAPEUTIC VALUE OF APIOL.—M.M. Joret and Homolle have obtained from the fruit of the common parsley, *petroselinum satiarum* or Apinus pitroselinum, a yellowish, oily, non-volatile fluid to which they have given the name of Apiol. This fluid is heavier than water; soluble in alcohol, ether, and chloroform, but insoluble in water. Its odor is peculiar and penetrating. In small doses it produces a powerful excitation of the system, a lively sensation of heat in the thorax and epigastrium, eructations, nausea, vomiting, and sometimes colic. In doses of from thirty to sixty drops it produces a kind of intoxication resembling that peculiar to haschisch or quinine. It is recommended as a febrifuge, in doses of fifteen grains or more; and though less powerful than quinine, deserves to be employed. It has also been used as a remedial agent in dysmenorrhœa and amenorrhœa. Its emmenagogue properties appear to be well established. It is best administered in capsules.—*Courit, Histoire Naturale Medicale.*

TREATMENT OF STRUMOUS OPHTHALMIA BY BELLADONNA INTERNALLY.—Dr. James Braithwaite, of Leeds, writes to *The Practitioner*, that he has for many years treated this affection by the internal use of belladonna given commonly in the form of the extract in an eight-ounce mixture containing four grains, and half a drachm of iodide of potassium. Of this, the dose for a child two years old is a teaspoonful every four hours. If no improvement results in a few days, the dose may be increased somewhat, and the quantity of belladonna in the mixture increased to five grains, and the iodide to a drachm.

He believes that belladonna should be given at once, without waiting until other means fail; that its efficacy is very much enhanced by the combination with the iodide of potassium; and prefers to use the extract of belladonna smeared upon the eyelid, eyebrow, and temple to the application of atropine to the ball, since the latter is apt to increase the irritation and photophobia, instead of relieving it. He advises the use of cod-liver oil, and finds change of air and counter-irritation with iodine paint sometimes useful in the later stages. Iron, he thinks, is injurious.

THE TREATMENT OF SYPHILIS.—At the Medical Congress of Lyons, a discussion took place upon the relative merits of mercury and iodide of potassium in syphilis, and the President, M. Diday, declared that mercury does not retard the appearance of secondary symptoms nor diminish the intensity, and he supported his opinion by an account of seventy-four cases; closing a brilliant and elaborate statement of his views by declaring that the intensity of syphilis depends less upon the medicines administered than upon the constitution and *regimen* of the patient.

TREATMENT OF FATTY TUMORS BY ABSORPTION.—Mr. John Gray, writing to the *Lancet*, of October 26, remarks the occurrence in a few cases of multiple fatty deposits in one individual, the number of distinct tumors generally varying from ten to twenty, but (it is said) sometimes reaching the number of a hundred. These deposits choose, for the most part, the arms, thighs, and the buttocks, as the seats of their growth. They do not attain great size, the tendency seeming to be in favor of a multiplication of sites rather than an increase in size of deposits. They are usually of firmer consistence than the ordinary variety of lipomatous growth; are flatter in shape, and lie more directly growth, and sometimes in closer union with the dermis. Their outline is usually, but not always well defined; they are, as far as I am able to judge, devoid of cysts, and are more or less painful on pressure according to their proximity to cutaneous nerves.

With the idea of encouraging absorption by liquefying the fat, Mr. Gray caused a patient, whom he had under treatment for this affection, to take baths, varying from 120° to 130°, as often as feasible; and he states the result to have been that many of these tumors were entirely removed, whilst the nuclei only of the firmer ones remained.

ABSORPTION OF RETAINED PLACENTA.—A. D. Robinson, M.D., Island Pond, Vt. (*Boston Med. and Surg. Jour.*, Nov. 7, 1872), relates the case of a multipara, aged 37, who he learned was delivered of a four-months fœtus, with very little pain or inconvenience, and without any after-birth. Four weeks subsequently he was summoned to her bedside, and found her suffering from quite a profuse uterine hemorrhage, attended with considerable gastric disturbance and vomiting, but no uterine pain. The patient was relieved of the vomiting by a laxative enema, which brought away a considerable quantity of hardened fecal matter; and of the uterine hemorrhage by opiates and rest. From this time the patient gradually recovered; and, if her evidence may be accepted, no placenta has been thrown off, either entire or in part, and she still continues in the enjoyment of perfect health. He adds that she is a person of unusual intelligence and reliability, and in every respect irreproachable character, which goes very far to strengthen her observation of the case. In closing, he remarks: As the question of absorption of a retained placenta is still *sub judice*, an accumulation of evidence may still be necessary to clear up this among other anomalous cases of obstetric surgery. This freak in obstetric practice would seem quite incredible were it not that cases of similar import have been long since met with.

AN UNUSUAL INJURY TO THE ELBOW-JOINT.—Mr. William Date reports, in the *Lancet* of October 26, a curious case, as follows:—

A boy, aged fourteen, was thrown from a donkey, and in falling struck upon his right arm, but in what manner was not made out. The arm was semi-flexed, and pain was caused by moving it. The elbow-joint was distorted and painful. The head of the radius was very prominent outside and below the outer condyle, and rotated freely with the rest of the bone. Above it was a deep depression in which the condyle could be obscurely felt. The olecranon could be felt below its usual position, resting with its extreme end against the trochlea. There was evidently no fracture of the ulna. While the patient was anæsthetized the position of the bones was rectified, the radius slipping into its place first, followed by the reposition of the ulna. It was then discovered that the extremity of the inner condyle was broken off. Following the reduction, an angular splint was applied.

CAFFEINE.—Dr. H. S. Purdon has lately been trying the hypodermic injection of caffeine in neuralgia from both functional and organic causes. Among his patients at the Belfast General Hospital was a case of "central neuralgia," which had resisted all plans of treatment. Under the daily use of caffeine hypodermically, commencing with half-grain doses, and increasing to one grain (dissolved in tepid water), very satisfactory results were obtained. Caffeine is superior to morphine in never producing sickness, which is so common where the latter is used hypodermically in any considerable dose. This salt has proved serviceable in allaying the sleeplessness of delirium tremens.—*The Doctor.*

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, February 1, 1873.

THE PERMANENT MEMBERSHIP IN THE STATE SOCIETY.

THERE is perhaps nothing during the coming session of the Medical Society of the State of New York that will more especially interest a large number of delegates than the election of permanent members. One of the main reasons why the election to permanent membership is considered such a desirable distinction, is doubtless due to the fact that so few of the large numbers of eligible persons can be successful. The by-laws of the Society provide for the choice of but two members from each district, and it is expected that while two gentlemen may be gratified with the distinction conferred upon them by the nominating committee, there are scores of others who are disappointed, and who claim that justice is not done them.

So often have many aspiring gentlemen been disappointed in their expectations of election, that they have been forced to conclude that there is something more than ordinary merit and reasonable good fortune in being among the lucky ones. To any one conversant with the workings of the Society for the past ten or fifteen years, it is quite evident that the suspicions of the disappointed ones have a very reasonable foundation in fact. In other words, it must be conceded by the majority of those specially interested in such elections, that the choice is due more to influence and political wire-pulling than to any claims which may be urged by a long candidature or other qualifications. There is no other explanation for the gross partiality habitually shown to different sections and different individuals by the various nominating committees.

Very often by certain self-constituted managers of the Society, the selection of some of whom on the nominating committee from year to year seems to be a foregone conclusion, conditional promises are made a year in advance. In political parlance this would be called "Ring" influence, and it means the same thing when applied to the strictly political management of the State Society.

Although the responsibility of appointing the nominating committee rests entirely with the President, it is but justice to him to say that the appointees are made with the best of intentions, and with a conscientious regard for the best interests of the Society. He has no particular rule to govern his appointments, except presumed fitness, and in his selections he very naturally drifts into the errors of his predecessors and names such as have frequently served on the same committee before. This, we take it, is one of the reasons why the Ring influence is so strong, and why there is such a small chance for those not skilled in wire-pulling for obtaining elections, particularly as permanent members of the Society.

In the choice of permanent members, exceptions must sometimes be made in favor of gentlemen who have rendered signal service to the Society, but these should only be exceptions, and as a rule the one in a particular district who has been eligible the longest period should be the first to be the permanent member from that district.

The election of permanent members from districts other than their own is a procedure which has from time to time received the unqualified disapproval of the Society, despite the number of "buncombe" speeches to the contrary. Until the Society rendered its decision against the injustice of the measure, the practice of assigning gentlemen from the city to the rural districts was so common, that country physicians began to think that they had no rights which the metropolitan was bound to respect.

In order to initiate a reform in regard to this election of permanent members, we must begin with the appointment of the nominating committee, and must suggest to the President the selection in the first place of gentlemen who have never served before. As far as it is consistent with this recommendation, let each member of that committee be the president, vice-president, or some other responsible officer of a county society. We can under such conditions be assured in the first place of the destruction of any Ring influence which may now exist, and of insure the meting out of justice for each district which a knowledge of the requirements makes possible.

This seems to us to be the simplest method of remedying many of the abuses of which the victims of many a deferred hope complain, but if better means can be devised to insure the same end, we shall in the interests of reform be satisfied to see them put at once into operation. We know of many gentlemen, particularly from the rural districts, who have been on the eligible list for a number of years, and who have seen others placed upon that list long after them, and elected to permanent membership without any delay whatever.

When those by seniority of eligibility find themselves thus repeatedly left out for the benefit of more favored ones, and as often told that they must be patient, or "wait until next year," we cannot blame them for insisting upon their rights. There is no argument against demanding of the members of the nominating committee the election of permanent members by virtue of this very seniority of eligibility. In fact that seems to us to be the only way of remedying an evil which has been increasing year by year and has been the means of doing a great deal to weaken the influence and to destroy the usefulness of the Society. We want to see simple justice done to those gentlemen who have waited so long for it; we want to see the forgotten districts rightfully represented, and the honors of the Society impartially distributed.

While speaking of the subject of election we wish to call the attention of the Society to the claims of Northern New York for the presidency. This district although it contains some of the best educated gentlemen in the State, has never yet been honored by the Society. It is now time that the claims of the gentlemen of the North be substantially recognized and duly honored.

A NAMESAKE FOR THE MEDICAL RECORD.

When The Medical Record was started, it was with the earnest purpose of making for it an individual reputation. As a consequence of such a determination, it was a matter of a good deal of concern with the Editor and the Publishers to select a name for the new journal which should be distinctive and appropriate—one with which it would be impossible to confound any other journal, living or dead. As a result The Medical Record was given. The fact was extensively advertised both here and abroad, and appeared in the usual trade-lists. Now at the end of its seventh year we are gratified to state that it has made for itself a reputation far exceeding the most sanguine expectations of its proprietors. This much being granted, we have considered ourselves enjoying an unquestioned right to all the benefits direct or indirect which should belong to the good name which our journal has gained for itself. Now, however, we are astonished to find that a new periodical in London has defiantly assumed our title, in direct violation of what might be considered honorable even among plagiarists.

If any party chooses to start a journal, that is purely their concern; but when they impudently appropriate our name, that very plainly becomes *our* concern. We always stand ready to encourage, in any way we can, any legitimate enterprise having for its object the advance of medical journalism, and we are gratified to acknowledge the fact when any periodical makes a mark for itself; but we confess to a little selfishness when there is an obvious danger of confounding our own name with any similar undertaking whatever. We are at a loss to explain this radical departure from what our English brethren choose to style honorable transactions. We have been in the habit of looking to them as our teachers in such matters, and have been forced very often to hide our ignominious heads as an acknowledgment of the power of their virtuous anathemas against violation of copy-rights and the like. It ill becomes us, perhaps, to call their attention to this little matter; but as pupils of theirs in the principles of honor and virtue, we cannot refrain from seeking a little more light on the subject—some explanation which shall reconcile an apparent discrepancy with former principles which we have been taught to believe admitted of no gainsaying.

We shall not quote what the bard of Avon says about stealing a good name, as it might lay us open to the charge of indorsing the sentiment, and might give rise to reflections which might be considered disrespectful to our teachers, in which event we should have no right to ask for any solution of what now appears to us to be inexplicable.

We do not even dare to presume that anything in a journalistic way on this side of the Atlantic is entitled to any notice from our cousins, else we might by a stretch of the imagination construe the taking of our name as a compliment to us.

THE HEALTH OFFICER'S DEPARTMENT.

Dr. S. Oakley Vanderpoel, the Health Officer of this Port, has, as appears from his Annual Report just published, successfully carried out some very important reformatory measures in his department, which commend themselves to the consideration of every one interested in quarantine affairs. For a long time, the abuses of power and the utter disregard of the interests of the commercial communities have been a disgrace to our government.

The trouble has been, that the relations which should exist between the commercial community on the one hand, and the general public on the other, have never been definitely settled. In fact, by some unworthy representatives of our profession who have been Health Officers, there has been no desire to change a system which insured so many extortionate percentages. The result was, that the merchants were forced to believe that whenever a reasonable opportunity offered itself for the Health Officer to claim perquisites, no appeal to his sense of fair dealing had any effect. He has been their traditional oppressor, and their acknowledged enemy. Dr. Vanderpoel started with a determination to confine his office to its legitimate health functions, and he has so far succeeded in practically solving a very difficult problem, and has shown that former enemies of quarantine mean, as a class, to be fair in their dealings, and submit to any judicious health enactments. We understand that a bill has been presented to the Legislature, contemplating changes consistent with the successful experiment of our present

incumbent making what was voluntary on his part, obligatory upon his successors. At a future time we shall have more to say on this point.

REPORT OF THE SURGEON-GENERAL OF THE NAVY.

SURGEON-GENERAL JAMES C. PALMER, U. S. Navy, informs us in his Annual Report for 1872 to the Secretary of the Navy, that the bureau of which he is chief, is now engaged in collecting and preparing for publication all the cases of pathological interest which have been accumulating for so many years past. This will doubtless prove to be a very valuable addition to our national medical literature; and when it is ready for publication, we should be glad to learn that Congress has voted a suitable appropriation.

Another subject in which Surgeon-General Palmer has taken an interest, is the establishment of a school of instruction for medical officers preparing for promotion, which shall comprise a museum for marine specimens, a library, a lecture-room, &c. This is an institution so much needed, that it is surprising that the idea has not been entertained before. Dr. Palmer proposes an appropriation of fifteen thousand dollars; certainly a very modest sum with which to commence. His model is the Medical School at Netley, England; a very succinct account of which is given by Medical Inspector Shippen, U. S. N., and embodied in the annual report to which we have refered.

Reviews and Notices of Books.

OUTLINES OF SURGERY AND SURGICAL PATHOLOGY, including the Diagnosis and Treatment of obscure and urgent Cases, and the Surgical Anatomy of some Important Structures and Regions. By F. LE GROS CLARK, F.R.S., Senior Surgeon to St. Thomas's Hospital. Second edition, revised and expanded by the author, assisted by W. W. WAGSTAFFE, F.R.C.S., Resident Assistant-Surgeon to, and Joint Lecturer on Anatomy at, St. Thomas's Hospital. Philadelphia: Lindsay & Blakiston. 1872.

THESE "Outlines," we are told in the preface to the first edition, comprise little more than the notes from which the author's lectures have been delivered, somewhat amplified; and are intended for the medical student. It makes no pretence to a comprehensive system of surgery, nor does it attempt to do away with those works, without a knowledge of which a student will become but a superficial practitioner.

It has been our lot to have seen many manuals of both medicine and surgery; and we have often wished that students could be induced to leave them on the shelves of the publisher, believing, as we do, that their tendencies are injurious.

In reference to the work before us, however, we are pleased to make an exception. It is indeed what it purports to be, the "Outlines of Surgery;" and so clearly is it written, and so rich in valuable information, that it needs but to be seen and examined to make it a work of value to the young practitioner. The pathology which is taught in this little work is quite in accordance with the more modern treatises on this subject.

Among the chapters which strike us as very timely and full of valuable information, are those on the diagnosis of joint-disease and the use of the thermometer in surgery.

Here and there through the book we find doctrines taught to which we might object: but there is far more to commend than to criticise; and this is no more than we should expect from such a writer and well-known surgeon as Mr. Clark.

We must confess our surprise, however, when we see that the student is told that in the majority of cases of indurated stricture of the urethra, without other mischief being present, "the cautious employment of potassa fusa is preferable to cutting; it is both safe and efficacious, especially when the stricture is irritable." Again, we are told that tapping the bladder above the pubes is seldom practised and rarely justifiable. Have the happy results of tapping in this region with the aspirator not yet reached St. Thomas's Hospital? Still farther, we are informed, in the chapter on amputations, that amputation at the knee-joint is not to be recommended.

And in the description of glaucoma, it is said the iris is usually contracted.

With some few exceptions like these, we think highly of the work.

EVOLUTION OF LIFE. By HENRY C. CHAPMAN, M.D., Member of the Academy of Natural Sciences, Philadelphia. Philadelphia: J. B. Lippincott & Co. 1873.

THE aim of this book or essay, as stated in the preface, is to present in a condensed and popular form the evidences in favor of the evolution theory, which supposes that the animal and vegetable worlds were gradually developed, and not suddenly created. The author starts with the hypothesis of the evolutionists, and argues that it is in harmony with other conclusions of science and the records of nature.

The principal part of the book is given up to the discussion of the last point; and zoölogy, botany, palæontology, and embryology are interrogated to establish the reasonableness of the theory.

The question of the vital force that gradual development calls for leads to the discussion of natural selection, to which the author heartily commits himself.

The last chapter is devoted to the origin of man, and the conclusions are not essentially different from Mr. Darwin's. Frequent allusion is made to the views of Lamarck, Darwin, Wallace, Spencer, Owen, and others, from whose works the data were chiefly taken.

Haeckel's classification of the order maintained in gradual development is the one adopted. The author does not regard it as unassailable, but, in general, correct; and he believes that the transitional forms that are now lacking to make a continuous chain will at some time or other be discovered. The subject is relieved of a good deal of its abstruseness by a pretty clear and precise style and frequent use of tables and wood-cuts. While most of us may be unwilling to reject the doctrine of divine creation, taking up as a substitute any theory, whether of spontaneous generation or evolution, which is admitted by their supporters to be still imperfect, we can at the same time get pleasure and profit from the discussion. We may take exception to the evolutionists in their methods of reasoning; but most of the facts are indisputable, and reflect great credit on the master minds who have collected and systematized them.

The author has doubtless had extraordinary facilities

for prosecuting his studies in this field, and has shown some originality in his deductions, though we believe few will feel ready to accept them at present.

ON A NEW METHOD FOR EXTRACTION OF CATARACT. By R. LIEBREICH. (Reprinted from St. Thomas's Hospital Reports, Vol. II.) Philadelphia: Claxton, Remsen and Haffelfinger. 1873.

THE operation for cataract proposed by Liebreich is a modification of the method described by von Gräfe. The objections to this latter method, which it is argued may be avoided by the operation now proposed, are urged as follows:

1. It is impossible to remove the lens without iridectomy. 2. The excision of the iris must be very extensive, else the iris tends to prolapse. 3. It is necessary to perform the operation above, in order that the enlarged part of the pupil may be covered by the upper eyelid; the removal of the lens upwards is far more difficult, on account of the tendency of the eye to roll upwards; and, consequently, 4. During the whole operation the eye has to be kept open by the speculum, and to be drawn downwards by the forceps. This is not only painful and injurious to the eye itself, but causes, 5, not unfrequently, prolapse of the vitreous body, to which a peripheral incision itself always tends. Prolapse of the vitreous body and hemorrhage into the anterior chamber are the chief impediments to a careful removal of all the *débris* of the cortex, and cause, 6, those grave forms of iritis which are kept up by the permanent irritation caused by the tumefied remains of the lens behind the iris.

Liebreich's modification consists in making the incision below, within the cornea, and without doing iridectomy. The smallest Gräfe's knife is used. In making the incision it is held with its back horizontal and backwards, the plane of the blade making with the horizontal meridian of the eye an angle of about 45°, and in the same direction is passed through the cornea. The points of puncture and counterpuncture are placed about one millimetre beyond the cornea, in the sclerotic, in such a situation that the centre of the but very slightly curved incision falls about two millimetres within the cornea's margin. After the incision is made the eye may be closed. The capsule having been opened, a Daniel's spoon is slightly pressed against the inferior margin of the cornea, and gentle pressure is made with the finger through the upper lid upon the highest point of the cornea. The lower margin of the lens then rotates forward, and, pushing the iris before it, passes over it, to appear in the gaping wound of the cornea. A slight downward pressure of the upper lid suffices to expel it.

The operation is done without anæsthesia, and the speculum and forceps are dispensed with.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, November 27, 1872.

DR. A. L. LOOMIS, PRESIDENT, in the Chair.

STRICTURE TREATED BY ELECTROLYSIS.

DR. ROBERT NEWMAN exhibited a small calculus for the purpose of referring to the history of the patient from whom it was discharged. The patient had suffered for nine years from traumatic stricture, the result of a perineal bruise while in cavalry service during the late war.

For a long time he was treated by bougies, until finally the stricture almost entirely closed, the urine merely dribbling away. Galvanic battery was used June 22, and a No. 3 passed the stricture.

Aug. 13th.—Under chloroform, galvanic battery (a steel sound as negative, twenty cells for twelve minutes), passed the stricture; next, without chloroform and with electrolysis, passed a bougie No. 15. Two hours afterward the patient left for home.

Sept. 9th.—Is worse again; endoscope shows a very irritable urethra, and the stricture closed up by plastic lymph thrown out after the last operation. Urethral emollient suppositories ordered, and the patient sent home.

Sept. 13th.—Returned to New York. No instrument passed the stricture. Dr. W. Maxwell present in consultation. No further attempts were made, thinking it not advisable to operate here, away from his friends.

Sept. 25th.—Dr. Newman operated in Hartford. Present Drs. Storrs, Fuller, Ellsworth, and Russell. Chloroform; galvanic battery, twenty cells; a steel sound No. 7 as negative; passed the stricture after the electrolysis was kept up for half an hour. Hemorrhage was unavoidable.

Subsequent to the operation, Dr. Storrs sent an account of the results of the case, which may be summed up as follows: First night after the operation, restless; at the first attempt to urinate only blood passed; the second time, before daylight, urine passed in a full stream. Morphine in half-grain doses every two hours through the night. Urethral fever for three or four days.

Oct. 1st.—More difficulty in urinating. Chloroform, and a No. 3 catheter passed, followed by a No. 5, and left for the night. An hour after, patient in great pain, and a restless night. Catheter removed in the morning. In evening attempted to pass water, but stopped; soon after the calculus voided. The patient subsequently made a good recovery.

IMPERFORATE ANUS.—PASSAGE OF A BUTTON IN THE BLADDER.

DR. POST presented a specimen taken from a child eleven months old, who at the time of birth was found to have an insufficiency of the anus. Dr. Bird, of Jersey City, whose patient the infant was, made an incision in the anal region, two inches in depth, and opened the pouched extremity of the rectum, giving vent to meconium. He made an effort to draw the incised gut downwards and attach it to the integument of the verge of the anus, but was unsuccessful. The wound healed, and the little patient lived in good health until a few weeks before death, passing the fæces in a liquid state through the urethra. The immediate cause of death was an obstinate diarrhœa.

At the autopsy the rectum was found to terminate in the prostatic portion of the urethra, where there was a free communication with the latter canal, and, through it, with the bladder. On examining the bladder, it was found to contain a small button with some clothing attached. This had probably been sucked off some part of the garments during the life of the child.

He next exhibited several sequestra removed from the lower part of the shaft of the femur of a patient, aged twenty-two. Five years ago he suffered an attack of osteitis, the result of exposure to cold. There was enlargement of the condyles of the femur together with the head of the tibia. Above the condyles sinuses in due time formed, through which

purulent matter and several small fragments of bone were discharged. About a fortnight since an incision was made over the region of the outer sinus, and the periosteum was found very firmly adherent to the involucrum, and it was with great difficulty detached. The involucrum was then chiselled away, and an opening large enough to introduce the finger having been made, the spiculæ presented were found lying loose in the cavity. The point of interest was the disproportionately large size of the cavity compared with the pieces of bone removed.

IRIDO-CHOROIDITIS—EXTIRPATION OF EYE.

He also exhibited an eyeball which he had enucleated three weeks before. The patient was a man aged 50, who had an attack of small-pox during infancy, since which time the left eye had been nearly destroyed by effusion. He had some slight perception of light, which he retained until twenty years ago, when from some cause unknown he lost the remaining remnant. There was, however, no disfigurement of the eyeball until ten years ago, when a little opacity of the cornea showed itself. This latter condition continued until the operation. Six weeks ago this eye became quite painful, and caused a sympathetic irritation of the opposite one. On examination a dense yellowish fibrinous mass was found occupying almost the whole of the anterior chamber. There was besides a thread-like membrane extending from the anterior to the posterior portion of the fundus oculi. It was evidently a case of long-continued irido-choroiditis.

Dr. Peters asked, in reference to Dr. Post's case, if it was not a common occurrence to notice a communication between the bladder and rectum.

Dr. Mason remarked that some years ago he collected a hundred cases of bladder-trouble, and in twenty of these the lower bowel communicated with the bladder or with the vagina.

A CASE OF MALIGNANT ICTERUS.

Dr. Mary C. Putnam presented a specimen of liver, for the opportunity of obtaining which she was indebted to Dr. Jerome C. Smith. The patient was a woman who for about two years had been addicted to habits of intemperance. Nineteen days before death, having been previously in apparent good health, she became suddenly jaundiced, and immediately took to her bed, with symptoms of great prostration attended with vomiting, fever, and a certain amount of intestinal hemorrhage. The temperature was very high, and the pulse never below 120. The patient was not under Dr. Smith's observation until four days before death. She never had convulsions, nor coma, but died with paralysis of the pneumogastric nerve, with congestion of the lungs simply as an ultimate symptom. The attending physician had discovered enlargement of the liver with these symptoms, but at the time—three or four days before death—there was a very considerable tympanitis, and a certain amount of serous effusion in the peritonæum.

With this history, she anticipated atrophy of the liver caused by acute hepatitis—the so-called malignant icterus—and was much astonished to find a liver very much enlarged, occupying as it did the entire right hypochondrium, extending over to the left hypochondrium, and weighing ten pounds. It was evidently fatty and was also deeply impregnated with bile, as were all the tissues in the abdomen. The jaundice persisted to the day of death, and the skin was deeply colored at the time of the autopsy. The serum in the abdominal cavity was very yellow, as also the fat in the mesentery, which was quite abundant; also the frothy fluid that was expressed from the lungs. The heart was small, but did not appear to be overcharged with fat. The kidneys were moderately large, and the cortical substance was evidently very fatty. The heart and kidneys proved to be the seats of fatty degeneration: the tubes of the latter organ were not however infiltrated with fat, the epithelium in most of them being intact. The liver presented nothing more than those appearances which belong to fatty liver.

To explain why this jaundice coincided with fatty liver, an attempt was made to ascertain if there was an obstruction to the course of the bile. Nothing of the kind was however found. The gall-bladder was empty. The small intestine was small in calibre and filled with mucus. There was not the slightest appearance of cirrhosis of the liver, neither were there any evidences of acute atrophy. The cause for the jaundice then was not clear: it might possibly have been due to the destruction of cells by excessive fatty degeneration—a very rare circumstance—or to the fatty degeneration of the muscular fibres of the heart with a consequent low pressure in the blood-vessels, favoring the entrance of the bile in the veins rather than in the ducts. The spleen was much enlarged and nearly dilluent.

Dr. Janeway remarked that he had seen several cases of fatty liver with fatal jaundice, and believed that such a result was due to pressure of the enlarged organ causing obstruction in the flow of bile.

Dr. Putnam.—But in this case the gall-bladder was empty.

Dr. Janeway.—The pressure might have been exerted above that point. We might explain the result in another way, by a defective function of the liver in consequence of degeneration of the cells. The liver fails to perform its function in this regard, the same way as does the heart when there is fatty degeneration of the muscular fibres.

Dr. Putnam did not think that there was such a strict analogy between the functions of the liver and the heart as was maintained by Dr. Janeway. In one, the loss of function was easily explained by a mechanical defect; in the other, the complex function of secretion was involved, admitting of no such explanation.

Dr. Loomis stated that there was one element which had not been considered, viz., the high temperature and rapid pulse, a very unusual concomitant of jaundice with fatty liver.

Dr. Putnam remarked that such conditions were the very ones upon which the diagnosis of malignant icterus was based, and which she was unable to explain by any of the autopsical developments.

Dr. J. C. Peters asked if there was any duodenitis present, and was answered in the negative.

DOUBLE UTERUS—STRICTURE OF ŒSOPHAGUS FROM ENLARGED GLAND.

Dr. Janeway presented a complete double uterus and double vagina, taken from a girl aged 13, who died of acute tuberculosis.

A second specimen was removed from a female patient of Bellevue Hospital, aged 34. She was admitted to the hospital in September. For six months before admission she had experienced pain on eating solids, which condition gradually increased until she was compelled to abstain from them altogether. There were found on examination evidences of phthisis in the upper portion of right lung. After a time the same distress was caused by fluids, and she finally died

from exhaustion. Her pain was referred first towards the cardiac orifice of the stomach, and later towards the top of the sternum.

The autopsy showed, in the first place, a consolidation of the upper part of the right lung; secondly, an enlargement, with cheesy degeneration, of the lymphatic glands around the division of the trachea and around each bronchus. Those glands on the right side had advanced to suppuration. The right pneumogastric nerve was pressed on by the enlarged glands at the root of the lung. At a point of the œsophagus corresponding to the bifurcation of the trachea a firm stricture existed, caused by an enlarged gland behind. The stomach was healthy. Besides this, there was found waxy degeneration of each kidney, and in addition a thrombosis of the left renal vein running into the vena cava. It had not produced any particular effect upon the kidney, and was evidently formed during the last days of life. In addition, there was brown atrophy of the heart.

PERITONEAL ABSCESS—PERFORATION OF FALLOPIAN TUBE.

The third specimen was taken from a patient admitted October 19,—a woman aged 35. She had an attack of intermittent fever three years ago, which left her with a pain in the side, and cough. Three weeks before admission this pain had mostly disappeared. Her general appearance was such as to give rise to the suspicion that suppuration existed somewhere; and having leucorrhœa at the time, it was deemed expedient to make a vaginal examination. There was then discovered a general rigidity—a binding down of the tissues of the pelvis. Pressing upwards and backwards and a little to the right, what appeared to be a small rounded tumor was discovered. As there had been considerable difficulty in passing water, a catheter was introduced; but the operation gave rise to such an amount of pain that the operator was forced to desist. The diagnosis made was cystitis, pelvic cellulitis, and perhaps a small tumor in the pelvic cavity. She continued in about the state described, when she began to sink, becoming drowsy, with some febrile movement, and finally died stupid, refusing towards the last to take any food. Her coma was doubtless due to the failure of her renal secretion, the result of an attack of acute interstitial nephritis.

At the autopsy the bladder contained a good deal of pus, and there was a fibrinous exudation on the posterior wall, in the centre of which was an opening large enough to admit the finger, leading into an abscess of the peritoneum. This abscess, filled with shreddy material, was closed by adhesive inflammation of the contiguous portions of the uterus, sigmoid flexure, and broad ligament. The mucous membrane of the uterus showed evidences of chronic inflammation, and the Fallopian tubes were twisted and dilated, having a perforation communicating with the abscess. There was also a small lobular pneumonia in the upper part of the right lung. The origin of the abscess seemed to be in a perforation of the Fallopian tube, while the perforation into the bladder was a secondary result.

Dr. Markoe asked if the patient with stricture of the œsophagus had been transferred from the surgical side, as he had a case of that sort which he had diagnosticated as cancerous.

Being answered in the negative, Dr. Delafield stated that he had made an autopsy upon the case referred to by Dr. Markoe, and found it to be due to a cancerous infiltration low down the œsophagus, two or three inches above the cardiac orifice.

SYPHILITIC DEGENERATION.

Dr. Delafield presented a microscopic slide containing a mounted cross section of the cauda equina, removed from a man aged 46, who had during his life been guilty of very intemperate habits. He had had sores upon his penis an indefinite number of times, the last being about five years before Dr. Delafield saw him. He had no secondary symptoms of any kind, being capable of following the occupation of a woodmoulder until six months before his death, when he began to have pains in his legs, most severe at night. Three months ago his pains increased in intensity, and were followed by numbness and loss of power of his lower extremities. This condition continued until he lost control over his rectum, the urine being passed with great difficulty.

He was admitted into Roosevelt Hospital one month before his death. At the time there was a large bedsore over the sacrum, a considerable loss of power in both legs—most marked in the left, as was also the diminution of sensation. He was able to walk, however, by leaning upon the shoulders of two persons. His general condition somewhat improved for a while, although his loss of power and sensation remained about the same, and he finally lost all control of the bladder, necessitating the daily use of the catheter. Finally, there was an attack of erysipelas, commencing in the bed-sore and extending down one thigh. The constitutional symptoms were very grave, and he soon sank.

The only organs presenting any interesting changes were the kidneys, bladder, and spinal cord. The bladder presented the evidences of acute cystitis; it contained purulent urine; the walls were reddened, thickened, and coated with fibrine. The kidneys showed evidences of acute suppurative nephritis. There were no changes in the cord itself. On examining the large nerves given off from its lower end, forming the cauda equina, it was found that on the front and left side three or four were matted together, in which situation was found a cheesy yellow tumor. In front on left side, and farther down, were two or three matted together, but here there was no tumor.

In the centre of this tumor was a small cheesy mass. It was of some interest to ascertain the manner in which this syphilitic inflammation had attacked the nerves in order to form this tumor. The nerves could be found in all stages of a change which culminated in the cheesy degeneration in the centre. The first change, shown by a section through the periphery of the tumor, was a thickening of the fibrous tissue between the nerve-fibres. This thickening increased, and the fibres became more and more compressed, so that finally only a confused mass could be recognized. Further in, a cell-growth was evident in this new fibrous tissue. These cells were small and rounded, such as we find in most syphilitic tumors. Ultimately these new cells seem, with the nerves themselves, to break down into the cheesy material already described.

There was a small gummy tumor on the internal surface of the cerebral dura-mater, and also nodes on the tibia.

POST-PERITONEAL TUMOR IN INFANT.

Dr. Jacobi presented a large tumor, with the following remarks:—This tumor, Mr. Chairman, has been removed from the body of a child who was three years and four months old at the time of its death. The patient was first presented at my clinic in this college (College Physicians and Surgeons) three months ago, with a large swelling of the abdomen. There

was dulness on percussion over a large surface; there was tympanitic percussion sound in the right iliac fossa, and upwards in the right renal region; there was tympanitic percussion sound also in the region of the left kidney, adjoining the spinal column. There was a tympanitic percussion sound about two and a half inches above the projecting umbilicus, in the median line and a little to the right. It did not feel like a uniform or solid mass, and showed five or six indentations. It showed a particularly large depression in the median line. It yielded a dull percussion all over, and also a more or less distinct sensation of fluctuation. This was so distinct in some parts that I believed that I had to deal with a cavity at least a part of which contained a liquid. There was now and then a peculiar crackling sound by pressure upon the tumor in the median line. The sensation of fluctuation was principally confined to the left iliac fossa. The crackling sound encouraged me to believe that I had a case of echinococcus; the hardness of portions of the tumor made it more probable that I had to deal with a conglomerate of cysts with an intermixture of solid masses—in a word, a cystic sarcoma. In a number of examinations the sensation of fluctuation was always distinct. I introduced an exploring needle a number of times and succeeded in obtaining nothing but blood. In two instances only I brought away a liquid. I examined this carefully, but not finding any hooks, I gave up the idea of echinococcus. Inasmuch as there was tympanitic percussion in the regions of the kidney, I gave up the idea of cystic disease of those organs. The spleen was the only organ that seemed to be involved in the growth, and I took it for granted that I had a case of cystic degeneration of that organ.

The report was that the child had been ill all his life; that about half a year before it was presented to my clinic, a swelling had been noticed in the region of the umbilicus, and a little above, extending in the direction of the liver, and that a physician in attendance had taken it for a "swelled liver."

At the time I saw the swelling it was mostly on the left side. The child was under observation for ten or twelve weeks. The tumor in the mean time grew so that it finally filled the whole abdominal cavity. Only in the right side the tympanitic sound continued constant. Moreover a little tympanitic percussion sound could be discovered in the left side, two or three inches above the anterior superior spine of the ilium. The child continued in pretty good condition, and after the tumor had become old I excluded the possibility of malignancy; there were no symptoms of peritonitis, and I began to think earnestly of attempting to remove the growth, large as it was, believing that I had to deal with an enlarged spleen. I did not entertain opening the abdomen with the knife, but determined, instead, to resort to the Vienna paste, thus producing an adhesive inflammation and allowing me to enter the cavity of the cyst, as I had previously done by the same means. The gentleman who applied the paste, selected a place somewhat different from the one I had pointed out, and the result was that a portion of the colon which covered the tumor was injured, and the child, during the last week or ten days of its life, suffered from a stercoral fistula. The child did very well with this fistula until a few days before his death, when symptoms of peritonitis showed themselves, and death finally ensued.

This portion of the abdominal wall, taken from the left side, shows the artificial opening made by the Vienna paste. The larger portion of this tumor was found in the left half of the abdominal cavity, and, lying against the vertebral column, presents a correspondingly deep groove. This groove would extend forward to here, and this is just that portion in which, especially in the beginning, I would have a tympanitic percussion sound. In here was a good deal of that sensation resembling fluctuation, and in that neighborhood I wanted to find my way into the cyst. The tumor is lobulated, and there are grooves everywhere; it appears to consist of a number of tumors which are either adhering to or growing out of an original stock. In this neighborhood you find fresh adhesions, the results of peritonitis, originating the last few days. This is the peritoneum which covers the whole tumor, and can easily be peeled off. There were no considerable adhesions with any organ of the abdominal cavity, with the exception, perhaps, of the spleen, which you see here in a normal state. The mistake in diagnosis was simply due to the fact that the tumor was so adjacent to the spleen that a dull percussion sound from it was continuous with the whole. The principal adhesions were found posteriorly. About the last dorsal and upper lumbar vertebræ it was, to a certain extent, difficult to tear off the tumor; and here you find a single place adjoining the upper lumbar vertebra, in which a portion of the mass is torn in an attempt to remove it. The rest followed pretty readily.

On cutting into the tumor there are found a large number of little cysts, some of them the size of half a walnut, and some the size of a pea. In a large number of instances there were apparently small hemorrhages, but those appearances are mostly due to an imbibition of the walls of the large vessels, which generally contain a good deal of loose fibrine. The consistency of the tumor varies, and I have since believed that the peculiar crackling sensation in my first examinations was due to my pressure upon the central portions of the tumor. The microscopical composition of the tumor is pretty uniform. There is some elastic tissue in it, and a good deal of cellular tissue, mostly found in the darker portions. The white portions consist mostly of spindle-shaped cells. The softer portion, one of which I show you, and one to which the tumor is principally attached, consists of round cells altogether, so that there is this portion which appears isolated. On opening it, it has the peculiar white color, and is evidently more consistent in consequence of the compression of the large tumor. This mass forms a separate tumor, which is embedded into the large mass, which it appears came very near being torn, and it might have been found as a free body. This also consists of round cells, with a very few spindle-shaped cells. The whole mass is a sarcoma with a very large number of cysts, and by no means what I took it for. The diagnosis was not correct, neither as far as its nature nor its locality were concerned. It evidently took its origin from the retro-peritoneal glands in the neighborhood of the lower dorsal and upper lumbar vertebræ. It cannot be expected that a tumor of this size (seven and a half pounds) would confine its origin to one point.

(To be continued.)

Chemical Probes.—M. Deneux, of Calais, in order to detect the presence in wounds of metallic bodies, employs threads impregnated with acetic acid, fixed to the extremity of a probe. After an examination the probe is withdrawn and the threads subjected to a reactive agent (iodide of potassium, cyanide of iron, ammonia), which indicates immediately and accurately the nature of the metal, if any be present (?).

Correspondence.

THE MECHANICAL LEECH.

To the Editor of the Medical Record.

Sir:—As several persons who have used the mechanical leech described by me in the Record for Nov. 1, 1869, have complained that its action was not satisfactory, more explicit directions for its use seem to be called for.

1. The incision should penetrate the whole thickness of the skin.

2. *Not more than two drops* of ether should be placed in the tube.

3. The tube should be held for ten or fifteen seconds in *hot* water, which should cover all but the mouth of the tube, where it is held by the tips of the fingers.

4. The tube should be applied *quickly* to the part, and held there until firmly attached, the skin having been previously moistened and any hairs removed.

Applied in this way, I have found the leech to be perfectly satisfactory, and much less unpleasant to the patient than the living animal. There is no delay in getting it to take hold, which saves a great deal of annoyance to both operator and patient.

It is *safer* than the living leech, as all hemorrhage ceases the moment the tube is detached.

I have had for a long time under my care a lady who has a tender spot in the spine, accompanied by the usual symptoms, and for whom all the approved forms of treatment, including galvanism, have been fruitlessly employed. The application of a couple of leech-tubes gives her immediate temporary relief, and by the repetition of this she gets on tolerably comfortably, and is slowly improving.

The Mechanical Leech has been adopted by the medical department of the U. S. Army, and is supplied to each military post.

Yours truly,

Andrew H. Smith, M. D.

New York, Dec. 6, 1872.

New Instruments.

GLASS PLEXIMETER.

By M. Hesse, M. D.,

Dresden, Saxony.

We present to the profession a new pleximeter manufactured of glass which was introduced at the meeting of naturalists and physicians in Leipzig, August, 1872. We received the following information concerning this pleximeter in a letter kindly forwarded to us by Richard Hesse, M.D., of Brooklyn, N. Y.:—

This form of pleximeter had its origin in the desire to procure a transparent medium through which to observe the skin when subjected to pressure. The method at present used—pressure with the finger—has the disadvantage in not being equable: and we are often left in doubt whether an existing redness of the skin, as is seen in cases of acute or chronic exanthematic diseases, orginate in hyperæmia or hæmorrhagia, or whether there is a combination of both. With this method we are also often not capable to determine distinctly such weaker differences of color as are existing when previous remains of inflammation or hæmorrhagia are still in the skin. The imperfection arises from the fact that the anæmia caused by the pressure of the finger no longer remains after lifting it, or will at least be modified by the re-entering circulation.

If we really endeavor to become perfect in our examinations and methods, this pleximeter will be a step forward, and will correspond more with the demands to be made on such an instrument. In this modification of the pleximeter—an instrument in the hands of almost every physician—I have succeeded without augmenting the instrumentarium. According to my experience the glass pleximeter is in no way inferior to those now in use (ivory, rubber, wood), excepting that it may *perhaps* be more easily broken. But beyond the advantage mentioned above there are others that will surpass that trifling disadvantage; these are due partly to the material, partly to the form and workmanship.

The following is a description of the instrument, as I have found it most suitable, after the inspection and examination of a great number of samples partly made by hand, partly in moulds.

The pleximeter is in the essential part formed after that of Fraube (Berlin). It is manufactured of the best Bohemian flint glass, blown into a metal form, cut and of course perfectly clear and transparent. It is 4 centimetres long, 2 centimetres broad, and a half centimetre thick. The ends turned up in right angles are 1¼ to 1½ centimetres high, and well rounded. The lower surface is slightly convex, and the edges touching the skin are well ground off, the corners likewise. Upon the face the French (centimetre) measure has been engraved, and divides it in 4 equal parts.

The depth of this pleximeter (½ centimetre) has in percussion as little influence as the much thicker finger; in comparison with the ivory pleximeter it has the advantage of not producing the peculiar clicking. Besides, the thickness of the instrument adds considerable to its durability. Its lower convex surface renders it much more adaptable than the straight ivory pleximeter; this advantage is still increased by its small dimensions (2.4 centimetre), and rounded edges and corners, so that it can always be applied even in the narrowest and most sunken intercostal spaces and fossæ clavicularis.

The height of the turned-up ends leaves the manipulation very easy for the examiner. By its given dimensions and engraved measure we are, without any further trouble, able to determine the limits in linear percussion, for which the turned-up ends as well as the edges of the plate may be likewise used.

Lastly, I mention that, after using it in contagious diseases, it may be cleansed and disinfected in acids, etc.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from January 5, 1873, to January 18, 1873.

Vickery, R. S., Assistant Surgeon.—Assigned to duty at Key West, Florida. S. O. 3, Dept. of the Gulf, January 6, 1873.

De Witt, Calvin, Assistant Surgeon.—Assigned to temporary duty at the Presidio of San Francisco, Cal. S. O. 168, Dept. of California, Dec. 30, 1872.

GIRARD, A. C., Assistant Surgeon.—to report by letter to the Commanding General, Dept. of the South, for assignment to duty. S. O. 12, War Dept., A. G. O., January 15, 1873.

WEISEL, DANIEL, Assistant Surgeon,—to report by letter to the Commanding General, Dept. of the South, for assignment to duty. S. O. 12, C. S. War Dept.

NAVY NEWS.

List of Changes in the Medical Corps of the Navy from December 12, 1872.

Assistant Surgeon C. A. SIEGFRIED, to the U. S. S. Richmond.

Assistant Surgeon J. M. R. SIMMONS died at U. S. Naval Hospital, Philadelphia.

Assistant Surgeon WM. A. CORWIN, to U. S. Naval Hospital, Chelsea, Mass.

Assistant Surgeon G. O. ALLEN, to U. S. Receiving ship Ohio.

Surgeon M. BRADLEY, to U. S. Navy Yard, N. Y.

Passed Assistant Surgeon F. M. DEARBORNE, to U. S. Storeship Supply.

Acting Assistant Surgeon J. W. ELSTON, to U. S. Naval Station, Mound City, Ill.

Passed Assistant Surgeon DWIGHT DICKINSON, to U. S. Naval Hospital, Yokohama, Japan.

Passed Assistant Surgeon H. M. RUNDLETT, waiting orders.

Medical Director GEORGE MAULSBY, retired.

Assistant Surgeon E. C. THATCHER, sick leave.

Assistant Surgeon W. B. DAVIS, U. S. Iron-clad Saugus.

Assistant Surgeon P. P. BIELBY, waiting orders.

Assistant Surgeon H. M. MARTIN, to U. S. Navy Yard, Washington.

Surgeon A. C. RHOADES, to U. S. S. Guard.

Surgeon J. S. KNIGHT, to U. S. Receiving ship Ohio.

Assistant Surgeon WM. G. FAREWELL, leave of absence.

Medical Items and News.

THE NAVAL MEDICAL BOARD FOR THE EXAMINATION OF CANDIDATES for admission and promotion in the Medical Staff of the Navy has reconvened at Washington with the following detail:—Medical Director William Grier, *President;* Medical Inspector Thomas J. Turner, Medical Inspector John S. Taylor, Medical Inspector Albert G. Gihon, *Members;* and Surgeon Philip S. Wales, *Recorder*. There are about twenty-five vacancies in the grade of Assistant Surgeon.

CLIMATE OF DENVER, COLORADO.—Dr. H. Norton, of Detroit, Mich. (*Detroit Review Med. and Surg.*, Sept., 1872), submits the following general observations concerning the climate of Denver, the result of a residence of two months there—April and May, 1872:—It is situated at the junction of Cherry Creek with the South Platte, in latitude 39°40', 5,317 feet above sea level. The brilliancy of the light is very disagreeable to those having a very sensitive retina, often necessitating the use of colored glasses, while the diminished atmospheric pressure so affects the physical condition of the eye as to require increased power of accommodation. Having on one side an immense plain to be heated by the sun's rays, and on the other a lofty range of mountains covered with perpetual snow and ice, great and sudden changes frequently occur. During the months of June, July, and August it seldom or never rains, and the heat is excessive, the mercury standing occasionally at over 100° in the shade. During this heated period storms of cold wind, called sand-storms, are frequent, so that persons out any distance riding for pleasure in mid-summer are obliged to take with them thick, warm wrappings to put on in case of a sand-storm, or run the risk of being dangerously chilled. Winter commences as early as the end of September, and continues occasionally as late as May, and consists of alternations of bright sunshine, clouds, rain, hail, snow and wind, the mercury sometimes sinking as low as 42° below zero. The pressure of the atmosphere at Denver is two and a half pounds to the square inch less than at the sea level. Nasal catarrh is quite common, and assumes a chronic form, the membrane becoming reddened and inflamed, then covered with a scab, which falls off or may be removed, but is speedily reproduced, the membrane refusing to heal. A certain number of asthmatics who visit this place are benefited, or even cured, but not all. Cases of asthma and chronic bronchitis are sometimes greatly relieved or cured by a residence here; and perhaps also threatened, but not developed, phthisis. The coming into this high altitude is especially dangerous to persons who have disease of the heart, the action of which is increased from five to eight beats to the minute; and to those whose lungs are much curtailed in their capacity to receive air. Acute rheumatism is very prevalent; and he heard of several cases of congested kidney, with albuminuria, due to sudden changes of temperature. The high altitude would seem eminently suited to persons troubled with apoplectic tendencies. This climate has been called tonic in its effects. On the contrary, it is prostrating, and a quantity of stimulants greatly in excess of what would be borne at the East is here tolerated. A disease peculiar to this region, called mountain fever, a kind of remittent with typhoid tendencies, is of frequent occurrence, and sometimes fatal.

EXTRAORDINARY FECUNDITY.—Dr. Becker-Lawrich de Rouneberg communicates to the society of "Gynécologie," under the name of extraordinary fecundity, the case of a woman married twelve years, and now pregnant for the nineteenth time. At first she was confined at the full term; then she aborted nine times in succession at four months, was delivered subsequently at eight months, and after that aborted seven times in succession at the fourth month. At the date of report she is again pregnant, but states that she feels the precursory symptoms of abortion.

PULMONARY TUBERCULOSIS.—According to reliable statistics, one-seventh of all the deaths throughout the world are due to consumption. In the United States, in the years 1859–60, the number of deaths from this disease was 49,082, being in the proportion of 13.79 per cent. to that from all other diseases.

AIKEN AND ITS CLIMATE.—Such is the title of a handbook, by W. H. Geddings, M.D., giving full particulars concerning the climate of that portion of South Carolina laid out in 1833 by a land-company, and called Aiken, in honor of William Aiken, its first president. Since the year 1845, its virtues have been known to the Northern public as a place of resort for invalids, possessing more tonic properties than the mild debilitating climates of Cuba and Florida.

In the winter of 1869–70 a little over 800 names of visitors were registered; in that of 1870–71 the number reached to 1,200, whilst in 1871–72 they exceeded 1,600. Two extensive hotels and a great number of private boarding-houses can accommodate all who desire to obtain relief in a mild climate, the supplies being obtained from the markets of Augusta, Charleston, and New York. It is a town of about two thousand inhabitants, situated on the most northern point of the South Carolina Railroad, 120 miles northwest from Charleston, and nearly six hundred feet above the sea level. The mean annual temperature for the last ten years was 61.95; for the months of October, 62.03; November, 52.27; December, 45.62; January, 47.05; February, 58.29; March, 53.29; April, 62.17; May, 69.75; June, 75.17; July, 79.90; August, 77.14; September, 72.54. The prevailing wind from the years 1860 to 1867, inclusive, was from S. W. in 39 months; N. E. in 18 months; W. in 15 months; E. in 12 months; S. in 4 months.

Dr. Goddings shows that the following conditions, which are essential to the comfort and well-being of phthisical patients, are found in that locality: 1st. Dryness, the first attribute of a good climate for consumptives. 2d. Elevated position. 3d. Fresh and pure air, which will permit, without discomfort, the patient to spend the greater portion of his time in the open air.

Deaths from Cancer in Philadelphia.—Dr. J. Stoeum Hough, of Philadelphia (*Obstetrical Gynæcological Soc.*, Sept., 1872), gives valuable statistics concerning deaths from cancer occurring in Philadelphia from January 1, 1861, to December 30, 1870; showing the relative proportion of males and females dying of this disease; and the percentage of women dying of cancer of the uterus. Total number of cases, 2,059. Cancer of the uterus, 413. The table indicates that, on an average, 232 women die of cancer to every man; or, 232 per cent. die of cancer of the uterus; or, 20.04 per cent. of the whole number, without regard to sex. There were only three cases of cancer of the ovaries, and six cases of cancer of male genitals. Of cancer of the breast there were 163 cases. The result shows that 862 women and 612 men died of cancer of organs not *peculiar* to their sex; showing that 40.74 per cent. more women than men die of cancer of organs common to both sexes. Of those women dying of cancer of the uterus, 60.8 per cent. die after the climacteric, while 39.2 per cent. die before this period. Cancer of the breast is still more fatal after this period, 78.5 per cent. dying after 45 years of age. Of women dying of diseases peculiar to their sex, 61.88 per cent. die before the climacteric, and 38.12 per cent. die after this period.

The author would suggest that the deductions derived from his tables may be of some value in the selection of cases in life insurance risks; for in general it appears that a woman's chances (probability) of life (so far as these affections are concerned) are nearly twice as great after the climacteric as before; that between twenty and forty years is the most critical period of her life; she is more than twice as liable to cancer after 45 years as she was before. Notwithstanding all this, in general women above 45 years (climacteric) have, he is persuaded, greater probability of life than men of the same age.

Southern Medical Colleges.—Dr. J. T. Darby has resigned his chair in the Medical Department of the University of South Carolina. Dr. Robert Gibbes, of Columbia, S. C., has accepted the position.

The Louisville Medical College has over two hundred students.

The Augusta Medical College of Georgia has been made the Medical Department of the University of Georgia.

Modern Medicine.—This is the subject of an Introductory Lecture, delivered October 8, 1872, at the Jefferson Medical College, Philadelphia, by J. M. Da Costa, M.D., newly-appointed Professor of the Principles and Practice of Medicine—published at the request of the students in attendance at this medical college. He alluded to the valuable aid of the microscope, thermometer, laryngoscope, and ophthalmoscope, and in speaking of the pulse-tracer, or sphygmograph—very useful, no doubt, in pathological and therapeutical inquiries, but of unsettled value as an instrument needed at the bedside—and all kinds of scopes and graphs, he looked upon this multiplication of instruments with some dread. The instruments to be employed should be simple ones.

He specified the following therapeutic subjects which are now engaging particular attention: anæsthetics, hypodermic medication, electricity. The remainder of the monograph is devoted to the great question connected with the science and art of medicine, namely, not how to cure disease, but how to prevent it.

The whole lecture is replete with eloquent and sound words to the medical student, and equally valuable to the practitioner, when he says that "one doctor publishes in medical journals incessantly and not differently from what is contained in every text-book; and another at a medical society, out of the fulness of his heart rather than out of the fulness of his knowledge, often enlightens his listeners on what they all know well."

The Turkish Bath.—Dr. R. E. Van Gieson, of Brooklyn, N. Y., has an admirable essay (in the *Medical and Surgical Reporter* of October 26, 1872) on "The History and Therapeutic Use of the Turkish Bath." The bath is traced as far back as Baalbec. Arriving at Greece and Rome, the remains of the ancient bath are found even to-day. "Nothing was too costly, no taste was too severe, no gold too precious to expend upon those temples founded for the health of the people. At the time of Cæsar and Sallust, Rome possessed 970 thermæ." The Turkish bath was first established on a sure footing in Great Britain in the year 1856. The pioneer of the Turkish bath movement in America, he says, is Dr. Chas. Sheppard, who first established the bath on Brooklyn Heights in 1863.

Washington University.—Dr. A. B. Arnold has been appointed to the Chair of Materia Medica and Therapeutics in the Washington University of Baltimore.

Vomiting of Snakes.—At the October meeting of the Vermont Medical Society, Dr. Bradford (*Medical and Surgical Reporter*, November 2, 1872) gave the details of the case, lately reported in the papers, of a man in Waitsfield having vomited snakes. The speaker took occasion to learn the exact facts, procured the snakes that were said to be vomited, and presented them before the Society. The patient, male, vomited two species of dead water-snake, about six inches in length; they were ejected in his own home and in the presence of his family, so he says there can be no mistake about the fact of their having been ejected from the man's stomach. The man had no knowledge of having swallowed anything of the kind, nor was he suspicious at any time that his stomach contained any such animals, but he remembers that when at work he was in the habit of drinking from some pools of water in his pasture; in that locality just such snakes abound.

New York Physicians' Mutual Aid Association.—The following gentlemen have been elected officers

of this Association for the ensuing year:—*President*, James Anderson, M.D.; *First Vice-President*, W. W. Reese, M.D.; *Second Vice-President*, T. C. Finnell, M.D.; *Treasurer*, E. H. James, M.D.; *Recording Secretary*, J. S. Monell, M.D.; *Assistant Recording Secretary*, S. Ayres, M.D.; *Corresponding Secretary*, J. C. Hutchinson, M.D.; *Trustees*, Drs. W. N. Blakeman, A. Underhill, C. L. Mitchell, Geo. A. Peters, Erskine Mason, E. Krackowizer, J. Kammerer, J. R. Van Kleek, W. J. Purcell; *Committee on Admissions*, Drs. F. A. Burrall, R. A. Barry, J. Weiner; *Committee on Applications*, Drs. James Anderson, E. H. James, W. W. Reese, A. N. Bell, J. S. Monell; *Committee on Benevolence*, Drs. Jared Linsly, J. C. Peters, Wm. B. Eager, J. C. Halsey.

Union University of the State of New York.—The Union College of Schenectady, the Albany Medical and Law Schools, and the Dudley Observatory, have been incorporated under the above title. The new Institution was inaugurated at Albany, December 23, 1872.

Ovariotomy.—M. Spencer Wells' record of 500 operations, with a mortality of only 25.4 per cent., is a magnificent triumph. Three hundred and seventy-three women, instead of being in their graves or miserable invalids wishing for death, have been restored to health.

In New Zealand, an English Army Surgeon was the pioneer of ovariotomy; in India, medical officers are performing this operation with success.

United States Marine Hospitals.—The report of Dr. John M. Woodworth, Supervising Surgeon U. S. Marine Hospital Service, to the Secretary of the Treasury, gives the subjoined exhibit of work performed in the U. S. Marine Hospitals during the past year: Four hundred and five thousand eight hundred and fourteen days of hospital relief were furnished to 12,302 sick and disabled seamen, being an average of 32_{16} days for each patient treated in hospital; 854 seamen, not requiring rest and treatment in hospital, were relieved by furnishing with medicine, making the total number of seamen relieved, 13,156; 521 deaths occurred, or a fraction less than four per cent. of the number treated.

The total cost of the service for the fiscal year, exclusive of erecting and repairing hospital buildings, was $396,263.11, being an average for each patient of $97\frac{6}{10}$ cents per day, against an expenditure of $453,082.42, or an average of $1.04 per day, incurred in the year ending June 30, 1871.

The department work of the Marine Hospital Service, which was formerly allotted to the Revenue Marine Division, has come under the immediate supervision of the supervising surgeon, assisted by E. K. Whitaker, Reinhold, Springsguth, and Dr. H. W. Santelle. Dr. Woodworth recommends the purchase of a site convenient to the port of New York, and the erection thereon of a pavilion hospital of the capacity of 200 beds. He also favors the erection of other pavilion hospitals; one on Angel Island, in the Bay of San Francisco, and another near Pittsburg, Pa. He particularly favors constructing all of the hospitals of wood, and destroying them after ten or fifteen years, both as a sanitary and economical measure, and building new ones in their stead. The present hospital buildings at Natchez, Miss.; Ocracoke, N. C; New Orleans, and San Francisco, are of no use to the service.

The first two named are located at posts where no applications are received for relief, and the last two are unfit for use.

Edible Earths.—Another kind of edible earth, other than the well-known Lapland variety, is found in Southern Persia, at Kirman, 5,000 feet above Salysteppe. The inhabitants of that district call it *Ghel-i-Ciech*, and use it in various culinary preparations, mixing it up with their food in different ways and forms. It is found in the shape of white nodules with gray spots. These nodules are of various sizes, varying between that of a walnut and that of an apple. Dissolved in water, this earth forms a whitish, impalpable sediment. It is soluble in dilute hydrochloric acid and in nitric acid; also in warm acetic acid. The solution is attended with a strong development of carbonic acid, and leaves a small residue of silica.

Death of the "King of Smokers."—Mr. Klaës, known as "the king of smokers," died recently in Holland at the age of 80 years. During his eighty years of life he smoked more than four tons of tobacco, and drank about 500,000 quarts of beer. By his will his oak coffin was lined with the cedar of his old Havana cigar-boxes, and a box of French caporal and a packet of old Dutch tobacco were placed at the foot of the coffin. His favorite pipe was placed by his side, with a box of matches, a flint and steel, and some tinder, for, he said, "there was no knowing what might happen."

Medico-Chirurgical Society of Montreal.—At the second annual meeting of this society, the following officers were elected for the ensuing year: *President*, Dr. R. Palmer Howard; *Vice-Presidents*, Drs. Reddy and Craik; *Secretary, Treasurer*, Dr. T. G. Roddick; *Council*, Drs. Godfrey, Schmidt, and Fenwick.

Medical Experts.—The subjoined resolutions, adopted May 9, 1872, by the American Medical Association, Section of Materia Medica and Chemistry, have been transmitted for publication, by E. Cutter, M.D., Secretary:—

Whereas, In all capital criminal trials, involving questions of medical jurisprudence, there is an obvious disadvantage in the testimony of scientific experts being made to appear partial and antagonistic, by their being engaged as witnesses upon one or the other side; therefore,

Resolved, That it is the sense of this Association that in important criminal cases, requiring the evidence of medical or chemical experts, the cause of justice will be promoted by the appointment by the court, in every such case, of a commission of experts, empowered to collect all purely scientific testimony bearing on the case, and report upon it to the court by which the case is to be tried.

Resolved, That, by the appointment of such scientific commissions, the present system of summoning chemical and medical witnesses, in criminal trials, might be dispensed with to advantage.

Resolved, That the same recommendation applies also to cases of accusation of surgical or medical malpractice.

Resolved, That the State Associations be requested to bring this matter, at an early date, before their respective legislatures.

Obstetrics in the Sandwich Islands.—Chas. H. Wetmore, M.D., has a readable paper on this subject, in the October, 1872, No. of the *Buffalo Medical and Surgical Journal*, based on his personal observation during a residence of twenty-two years in Hawaii.

When the period of utero-gestation is nearly completed, many of them drink freely of a mucilage prepared from the inner bark of the "Haw" or Hibiscus tree. When labor is fairly commencing, the patient assumes a sitting posture upon a hard pillow of stone, with her husband or some other intimate male or fe-

male friend, resting upon his or her knees, behind her, whose duty it is to grasp her above the abdomen in such a way that he or she can press down with considerable force upon the uterus and its contents, never relaxing this grasp to allow the fœtus to recede; the accoucheur's position is in front, and he or she has but little to do but receive the child; if the case is at all tedious or prolonged they imagine it a "cross birth," or that the child is dead, or something else, never certain what presentation exists until the head or some other part shows itself externally. They seldom allow the cord to be tied or cut until the after-birth comes away.

PHOSPHORUS IN NEURALGIA.—Mr. Bradley, of Manchester, Eng., speaks of having excellent results in some cases of neuralgia, from the administration of phosphorus. He says: "It will not cure every case; but when the neuralgia is accompanied by much nervous waste, as is often the case in nervous and sanguino-nervous temperaments, then it rarely fails to put an end to the paroxysm."

THE annual report of the Librarian of the New York Hospital shows, that although the hospital itself is suspended, the Library, which formed one of its attractions, is still receiving the fostering care of the Governors. During the past year it has been increased by the addition of more than four hundred volumes, including a complete series of "Schmidt's Jahrbucher," "Canstatt's Jahresbericht," and its sequel, "Jahresbericht über die Leistungen und Fortschritte," &c.

Also, "Virchow's Archives," "Bulletin de la Société d'Anatomie," "Pflüger's Journal de Physiologie," and various others of much value. In the various departments of Medicine and Surgery, the additions have likewise been quite numerous, and a liberal appropriation has been made by the Board for the present year.

The Library is conveniently located, at No. 13 West Eleventh street, a few doors west of Broadway; is open daily from 1.30 to 3.14, and may be consulted during those hours by such members of the profession as choose to avail themselves of this privilege. Number of volumes, 9,074.

DR. J. J. CALDWELL, formerly of Brooklyn, has removed to Baltimore, Maryland.

WEST SIDE GERMAN DISPENSARY.—This is a new institution, located at 232 W. 40th st., designed for the gratuitous treatment of patients of all classes and nationalities. The staff consists of Drs. E. Gruening, F. Buchser, L. Limpert, S. Teller, and L. Weyland.

THE TONER LECTURES.—The first of this course of medical lectures in Washington, D. C., will be delivered in February, 1873, by J. J. Woodward, M.D., U. S. A. Prof. C. E. Brown-Séquard, M.D., will deliver the second in April, 1873. The third will be given by Prof. Alonzo Clark, M.D., of New York.

PROF. HUXLEY is the new Secretary of the Royal Society, in place of Dr. Sharpey, resigned.

THE LATE DR. WM. S. REYNOLDS—At a meeting of the Medical Board of the Roosevelt Hospital, held December 16, 1872, the following resolutions were adopted:—

Whereas, Dr. Wm. S. Reynolds, late House-Surgeon to the Roosevelt Hospital, has been suddenly taken away by death while in the active discharge of his duties; therefore,

Resolved, that the Medical Board of the Roosevelt Hospital desire to express to the family of Dr. Reynolds their appreciation of his high character and attainments, and of his faithfulness in the performance of the duties devolving upon him, and to offer their sincere sympathy in this heavy affliction, by which he has been cut off on the threshold of a promising and honorable career.

Resolved, that these resolutions be entered upon the minutes of the Medical Board, and be published in the *Medical Record* and the *New York Medical Journal*, and that a copy be forwarded to the family of the deceased.

ROBT. WATTS, M.D., *Secretary.* A. CLARK, M.D., *President.*

MISSIONARY DISPENSARIES AT MADURA AND DINDIGUL, INDIA, ETC.—The Annual Report of the American Board of Commissioners for Foreign Missions, 1871, gives the following particulars concerning the dispensaries under the charge of American medical missionaries: In the Madura dispensary, under the charge of Dr. Henry K. Palmer, there were treated, during the year 1871, 3,160 new cases. An addition to the dispensary was made, 45 by 17 feet.

Rev. Edward Chester, M.D., reports as follows respecting his dispensary at Dindigul: There has been a total of 12,212 patients, of which number 5,948 were new cases. Patients came from 415 different villages. Erections of suitable buildings have commenced.

In the Manepy dispensary, Ceylon Mission, under the charge of Samuel F. Green, M.D., 1,185 patients were registered during the year. A class of eleven, having pursued a thorough course of medical study, graduated in December, 1871. Dr. Green is also carrying through the press a work on Anatomy, and one on the Practice of Medicine, in the Tamil language, and is preparing a volume on Chemistry, which is well advanced.

Dauphin W. Osgood, M.D., Foochow Mission, treated, in all, between eight and nine hundred patients, and performed twenty-four important surgical operations, which, with two exceptions, were successful. He also treated thirteen cases of attempted suicide by taking opium.

THE LARGEST HUMAN BRAIN RECORDED.—The *British Med. Jour.* contains a statement by Dr. James Morris, that in 1849 a brain weighing over seventy-four ounces was removed from a bricklayer, aged 38, who had died in Guy's hospital from pyæmia, following an operation for hernia. The height of the man was five feet nine and a half inches. "There was the utmost difficulty in obtaining a satisfactory history of him. His wife and his landlady gave different accounts. It seemed that he was a native of Sussex, and had left his village and changed his name, on account of some poaching troubles; that he was not very sober; had a good memory, and was fond of politics. He could neither read nor write." Professor Flint, Jr., in his last volume on the Physiology of the Nervous System, gives Cuvier's brain as the heaviest on authentic record,—64.33 oz.

New Publications.

A HANDBOOK OF THERAPEUTICS, by SIDNEY RINGER, M.D., Prof. of Therapeutics in University College, etc. Third Ed. New York: W. Wood & Co. 1872.

HANDBOOK OF PHYSIOLOGY by WILLIAM SENHOUSE KIRKES, M.D., Edited by W. MORRANT BAKER, F.R.C.S. 8th Ed. Philadelphia: Lindsay & Blakiston. 1872.

Medical Society of the State of New York.

SIXTY-SEVENTH ANNIVERSARY.

FIRST DAY.—MORNING SESSION.

THE Society met at 11.15 A.M., on Tuesday, Feb. 4, 1873, in Perry Hall, Albany; and the meeting being called to order by the President, DR. CORNELIUS R. AGNEW, of New York, the exercises were commenced with a prayer by the REV. DR. CLARK, following which the President delivered his

INAUGURAL ADDRESS.

The President referred to the increase of interest exhibited on the part of the public and the press, in matters which, until a recent period, had been considered to be the almost exclusive property of our profession. Whereas formerly but little or no attention had been directed to removing the avoidable causes of disease, at the present day some of the most important acts of legislation is in that direction. In this, however, we are far behind Great Britain, where the demand for skilled medical officers to carry out the provisions of the law is so great, that one thousand are now needed, the President said, in order to make the Factory Act, alone, effective. Recent communications to our medical journals have shown that, as regards their responsibility of protecting the public against disease, our profession is exposed to the charge of dereliction; and, in order to encourage greater care and attention on the part of physicians with regard to matters belonging to sanitary science, he advised the passage of a resolution requesting the county societies in this State to appoint committees to take account of the subject of vital statistics, and communicate with a standing committee of the State Society, to be established for the purpose. The effect of such a measure would do much to encourage and direct sanitary legislation, and correct the anomaly, which now too often exists, of health-boards being managed in the interests of political organizations. A bill, the President said, had already been introduced into Congress, to provide for the establishment of a National Bureau of Sanitary Science; and he warmly advised its endorsement by the Society.

In regard to the matter of medical education, DR. AGNEW referred to the changes lately made by Harvard University, and recommended that the Society encourage their adoption by the schools in our own State. At the same time, since the present form of organization of our medical colleges has been the result of personal efforts on the part of the gentlemen comprising their faculties, this consideration and others—such, for example, as the pecuniary interest involved, should make the Society cautious in its criticism of institutions in which many of the most respected members of the Society had received much of their training. The college faculties, he assured them, would always be pleased to listen to, and would act upon reasonable suggestions.

The President spoke earnestly in favor of even partial endowment of the medical schools, so that they might be enabled to establish other chairs than those at present included in their curricula; and organize laboratories for the practical study of chemistry, physiology, and pathology. He also spoke of the desirability of modifying the course of instruction, so that students should learn more by recitation, and less from lectures and clinics.

Next the President referred to the views which have been expressed, that the county medical societies ought to be the sources from which delegates should be chosen to attend the State and National associations. He also remarked the tendency which exists to modify our rules of ethics; and impressed upon the Society the necessity for considering impartially all questions of this nature which might be presented to them, although they might sometimes be unpleasant.

The care of the epileptics and paralytics in our State deserves, he thought, most careful consideration on the part of the government. In this, also, we are quite behind England. In London alone there are several hospitals for this class, whereas, with the exception of the one on Blackwell's Island under the care of the Commissioners of Public Charities and Correction, there are none in this State; and epileptic and paralytic patients are either kept as common paupers in the county houses,—where they are neglected and are a constant source of annoyance and trouble,—or are confined in lunatic asylums, where they do not belong, and where they occupy space which is urgently needed for the legitimate inmates of such institutions. He recommended that the Society should appeal to the State to either build separate hospitals for them, or make additions to the county houses of sufficient size for their accommodation and classification.

Lastly, he hoped the Society might impress upon the authorities the justice of protecting the indigent poor of the State from harsh and too rigorous treatment. While nothing should be done to encourage voluntary pauperism, regard should be had for those who are helplessly and often undeservedly poor.

Before closing he reminded the Society of the resolution passed at their last meeting, requiring those who undertake the private instruction of students in medicine to exact of them that they shall first procure of the censors of their county society a certificate of fitness as regards preliminary training.

On motion of DR. VANDERPOEL, such portions of the President's address as required action on the part of the Society, were referred to a committee of three, to be appointed by the Chair.

On motion of DR. FRAZIER, a committee was appointed to invite the Governor, and such members of the Legislature as were physicians, to take part in the meetings of the Society.

COMMITTEES.

The President then announced the following committees:

On Credentials—DRS. W. H. CRAIG, of Albany; A. L. SAUNDERS, of Brookfield; and C. E. RIDER, of Rochester.

Business Committee—DRS. ELLSWORTH ELIOT, of New York; J. V. KENDALL, of Baldwinsville, and G. H. HUBBARD, of Lansingburgh.

Committee on Arrangements and Receptions—DRS. J. V. P. QUACKENBUSH and WM. H. BAILEY, of Albany, and DARWIN COLVIN, of Clyde.

Committee on Medical Ethics—DRS. THOS. HUN, of Albany; E. R. SQUIBB, of Brooklyn, and D. B. ST. JOHN ROOSA, of New York.

Committee to Invite the Governor and Legislators—DRS. ROBERT FRAZIER, of Camden; LEWIS POST, of Lodi, and THOMPSON BURTON, of Fultonville.

MISCELLANEOUS BUSINESS.

Dr. G. W. Barr, of Titusville, Delegate from the Pennsylvania State Medical Society, was then introduced. Dr. Barr formerly resided in this State, and, during our late war, served as surgeon under a commission from Dr. Vanderpoel, then Surgeon-General of the State.

Dr. Eliot, Chairman of the Business Committee, announced that Dr. Wm. C. Wey, of Elmira, would read for Dr. Geo. Burr, of Binghamton, who was absent, a paper based upon "A Case of Occlusion of the Femoral Artery from Fracture of the Femur, followed by Mortification and Amputation." In this case, fracture of the femur occurred at the junction of the middle and lower thirds. The limb was placed upon an inclined plane, with loose dressings. Next day the leg was found to be cold, free from swelling, pale, and without pulsation in its vessels. At a later period the skin became gangrenous and, an irregular line of demarcation having formed, was amputated through the knee. The patient recovered. Examination of the limb showed that the gangrene depended upon cutting off the circulation through the artery, and not from the cause so frequently blamed when mortification follows upon fracture, viz:—tight bandaging. It was owing to the *medico-legal* bearing of the case that it was reported.

Dr. Bridges, of Ogdensburg, read a paper entitled "Disease of the Left Ovary, resulting in fatal Hemorrhage." The patient was estimated to have been about six weeks pregnant. A solution of continuity in the tissue of the organ named was the only source discovered from which the hemorrhage could have taken place into the abdominal cavity, which, with the Fallopian tube, was filled with blood.

The following papers were read by title, and followed the usual course:—"Obituary Notice of Dr. Darius Clark," by Dr. B. F. Sherman.

"Hernia," by Dr. J. H. Pooley, of Yonkers.

"The Effects of Railroad Travel on the Health of Women," by Dr. Ely Van der Warker.

"Idiopathic peritonitis," by Dr. Joseph Lewis.

Dr. D. B. St. John Roosa, of New York, read portions of a paper entitled, "History of the Progress of Otology," which gave an excellent idea of the very rapid advance which has been made in this branch of surgery.

Dr. H. Knapp observed that the paper, to which he had listened with the greatest interest, had mainly been devoted to practical purposes, which was eminently proper, considering the character of the Society. There had been, however, one chapter worked out, of late years, which he thought to be one of the most sublime triumphs made in the province of medicine during that period; that was, the anatomy and physiology of the cochlea. Long ago it was known that the pitch of sound depended upon the number of vibrations, but it was left for modern investigations to show us what it was in the ear which perceived the number. Helmholtz said, some years ago, that Corti's organ, now called the *zona arcuata*, was divided into arches of different densities, and, perhaps, different lengths, so that they could vibrate at different rates of velocity, and so, he said, when a sound is produced by an instrument, it would put in sympathetic vibration some of the arches.

An obstacle to this theory was the absence of Corti's organ in birds. Anatomists have found that the last filaments of the acoustic nerve pass underneath the arches of Corti and unite with certain cells, which are now called "hearing-cells," and are stretched between two tight membranes, one of which is made up of dense stripes of tissue, and called the *zona pectinata*. These stripes are connected by a cement-like material, less dense in structure, so that they can, to a certain extent, vibrate independently. To those hearing-cells and their *annexa*, the last filaments of the auditory nerve have been traced, and the mode by which they are acted upon by sound is supposed to be this: A sound being produced outside, easily puts into vibration one of these cells, or its bristle-like continuation, and in so doing puts into co-vibration the nerve filament connected with it. Thus far it has been traced anatomically; but the theory is more than hypothesis, it is based upon anatomical facts in connection with physiological experiments. In certain *amphibia* the "hearing-bristles" are outside the body, and these animals have been placed in a vessel filled with water, and observed with a microscope while a loud sound has been produced, and it has been seen that certain tones produced vibration of certain sets of hearing-bristles, and of no others; so that a modified theory of Helmholtz is now in harmony with our present knowledge.

As to some of the practical applications of this, it may readily be imagined that the hearing organ might show deficiencies of this delicate apparatus, and one of them may be illustrated by the working of a double-stringed piano. Sometimes the two sets of strings may not be in unison, one being tuned a little higher than the other. So people may hear double—that is, the same sound will appear to one ear higher or lower in pitch than it does to the other, according to the relaxation or tension of the *zona pectinata* of the diseased side.

There are other and rarer cases, of which Dr. Knapp had seen a few, in which, besides hearing the original sound, the patient also hears two, three, or even four neighboring sounds, though the latter are less distinct. This may be explained by the cement between the bristle-like rods being thickened by exudation, or other morbid processes which lead to sclerosis, so that the bristles cease to vibrate independently. This condition may be called *diplacusis monauralis*, whereas the variety before mentioned is termed *diplacusis binauralis*.

With regard to the practical importance of diseases of the labyrinth, the doctor mentioned one point for the consideration of the Society, viz.: Some acute affections—cerebro-spinal meningitis for example—produce disease of the labyrinth, destroying the hearing power totally. Nothing is seen in the organ of hearing, however, on physical examination, and the patient remains deaf after his recovery from the disease. At the beginning of the disease there may be some slight catarrh of the pharynx and middle ear, which disappears, leaving an incurable deafness. When such cases come before us after the recovery from the general disease, and no sound is perceived by the patient, we may say with certainty that they are not amenable to treatment.

Dr. Roosa said he would be sorry to consume the time unnecessarily, but wished to speak two or three minutes on a point raised by Dr. Knapp in regard to the disease occurring in cerebro-spinal meningitis. He hoped that practitioners who have the opportunity would make *post-mortem* examinations with reference to the condition of the ear. We are painfully at fault in regard to our knowledge as to what *does* occur in the ear, in this disease, and he was inclined to expect with Voltolini that cases of inflammation of the labyrinth are sometimes mistaken for diseases of the meninges, when what would be proper treatment for the latter

would prove destructive to any attempts at treating the ear trouble—as, for instance, the application of ice-water to the head.

He only wished to ask his brethren and fathers in the profession if they would look a little more closely into this matter, or give aural surgeons an opportunity to see the *post-mortem* condition of these parts.

Dr. Wm. B. Alley then read a paper on "The Ultimate Results of Nerve Injuries in Gunshot Wounds." A point of special interest in the paper, which was based on the observation of over thirty cases, was the statement, that a man who had received a gunshot wound of the face had profuse perspiration of one cheek during mastication.

Dr. Wm. M. Chamberlain, referring to this fact, said the subject of unilateral perspiration had recently received considerable attention from Dr. Sidney Ringer, of London, and an article from him on the subject had recently been published in "The Practitioner." Dr. Ringer had signal success in treating some of these cases with sulphate of atropia.

Dr. B. F. Sherman said that ten years ago a member of his own family had, as the result of typhoid fever, inflammation of a parotid gland, which terminated in suppuration and destruction of apparently all of the gland. In this case precisely the same condition existed as in the case mentioned by Dr. Alley. When the person takes food or masticates at all, perspiration stands in large drops on that side of the face, or trickles from it.

Dr. Knapp wished to know if the excessive sweating was confined to the numb side, which Dr. Sherman said he remembered distinctly to have been the case. In fact, it was never dry. Dr. Knapp said that he remembered a case—one-sided facial paralysis—from aural disease, in which this side of the face did not perspire. He had explained this fact for himself by the opinion of *Claude Bernard*, that secretions in general are under the control of the motor nerves. The profuse perspiration on the affected side, in Dr. Sherman's case, he was disposed to attribute to hyperæsthesia of the nerve due to the irritation of a cicatrix, which might be deeply seated.

The Chairman of the business committee asked if the Committee should take cognizance of any paper presented by an invited guest, and Dr. Roosa proposed the following:—

Resolved, That the Committee be requested to consider papers that may be presented by invited members of the Society, and cause them to be read, if thought expedient.

Dr. Frazier moved, as an amendment, that such papers take the course that they would, if emanating from a delegate or permanent member; which resolution, with amendment, was adopted.

The President then announced the following *Committee on the President's Address*:—

Drs. S. O. Vanderpoel, J. P. Gray, and Ernst Krackowizer.

The Chairman of the business committee reported no further business for the morning, but said that the large number of papers which had been handed in to be read, required that gentlemen who proposed to present papers should hand them to the committee at once, with a statement of the probable time they would consume.

The Committee on Credentials presented a list of invited guests.

Dr. Craig, of Albany, moved that the two contesting delegations from Niagara County, and their papers, be referred to the committee on medical ethics.—Carried.

The Society then took a recess until 3 P. M.

FIRST DAY.—AFTERNOON SESSION.

The meeting was called to order at 3 P.M.

The President in the chair.

Dr. J. W. S. Gouley, of New York, read a paper on Perineal Lithotrity, an operation practised by Dolbeau, of Paris, since 1862, by which the membranous portion of the urethra is opened; the prostate and neck of the bladder dilated instead of being cut, and a large stone crushed and the fragments immediately extracted; the whole being done at one operation.

An incision through the perineum $\frac{13}{16}$ of an inch in length, commencing at the anal margin, is dilated by an instrument which Dr. Gouley exhibited, and which is afterwards passed into the bladder through the prostatic portion of the urethra. The tissues having been stretched to the diameter of twenty *millimetres*, the stone is to be extracted entire, provided it does not exceed two *centimetres* in diameter; in case it is larger it is to be crushed and the fragments extracted.

For the crushing of the stone, Dr. Gouley recommended forceps which are modeled from those recently described in The Medical Record and constructed by Mathieu, of Paris.

Three cases were reported by Dr. Gouley as having been operated on by him by this method, with the most favorable results.

Dr. Ernst Krackowizer, of New York, in speaking of this mode of operating for stone, said that it was always a strong argument in favor of an operation if an operator chanced to stumble into methods which have been foreseen by others. This had been the case with himself as regards this procedure, and he went on to relate two cases:—

A lieutenant of volunteers had been shot through the pelvis; the ball entering the sacrum and emerging above the pubes. Fæcal matter and urine had escaped from both wounds, and small fragments of bone had passed *per urethram*. Some of these fragments of bone became lodged in the membranous portion of the urethra, and were not dislodged, despite all the ingenuity brought to bear upon them. In this emergency he came to Dr. Krackowizer, who performed the operation of cutting into the membranous portion of the urethra, and by this means the bones were removed. The doctor made an effort to pass his finger into the bladder, and was amazed at the facility with which it could be done—he fairly "walked" into the viscus. Examination detected the presence in this organ of a large phosphatic calculus, which was easily broken and removed. This centre of the body was a spiculum of bone. No untoward results followed the operation.

At the New York Hospital, an operation had been made for the removal of calculus, in which this mode of operating was adopted; the stone was seized with forceps and efforts made for its extraction. This was rendered difficult, as was afterward discovered, by the irregular form of the calculus which caught against the base of the bladder. Its final extraction caused a laceration of the prostate body, which did not, however, involve the neck of the bladder. Dr. Krackowizer thought highly of the method proposed by Dr. Gouley.

Dr. J. C. Hutchinson, of Brooklyn, also spoke favorably of it, 1st, on account of the small opening required; and 2d, for the reason that the prostate is neither torn nor cut. He did not consider it important to limit the incision through the tissues to the $\frac{13}{16}$ of an inch, as recommended by Dr. Gouley, but considered that no harm would come from a much larger one if, thereby, the ease of operating could be facilitated.

One disadvantage in this mode, is the length of

time required to remove a stone at one sitting, by breaking it, and washing out the fragments; he would himself be in favor of nicking the prostate and removing the stone entire, rather than permit a delay of thirty minutes.

The PRESIDENT then announced the *Committee on Nominations*, as follows:—

First district, Dr. J. C. Hutchinson; second district, Dr. J. Foster Jenkins; third district, Dr. H. B. Whiton; fourth district, Dr. Alexander Ayres; fifth district, Dr. Alonzo Churchill; sixth district, Dr. Wm. C. Wey (chairman); seventh district, Dr. Caleb Green; eighth district, Dr. H. W. Dean.

DR. S. O. VANDERPOEL, Chairman of the committee appointed last year to consider the question of changing the time for meeting, read the following report:—

THE Committee appointed to consider the advisability of changing the time of meeting report, that in the consideration of this question it is natural to inquire why the present time of meeting was originally selected, and whether any objections exist to the proposed change.

"The Society now numbers so many years that it has been difficult to obtain the desired information. Several members who were interrogated were unaware of any particular reason which either now, or formerly, rendered the present time of meeting particularly desirable. One or two expressed an individual preference, as it afforded a slight relaxation during the more busy period of professional cares. From reliable information, however, it may be stated, that the present time of meeting was originally selected in order that the Society might hold its meetings during the sessions of the State Legislature, and that physicians who were legislators might be present during the meetings of the Society.

"If it be objected to the change under consideration, that the Society and the Legislature ought to hold their meetings at the same time, in order that any subjects which require legislation might be more easily considered and acted upon, we may reply that such subjects could be more fully discussed and matured if the Society met at a date previous to the session of the Legislature. In short, it is believed there are no insuperable objections; or if so, they have not been presented to the notice of the committee. But, if there are *no objections* to a change in the time of meeting, there are considerations which *favor* such a change very decidedly.

"The inclement season of the year in which the session is now held, makes traveling difficult, disagreeable, and in some parts of the State almost impossible. As an illustration of this fact it may be mentioned that at the last meeting of the Society (1872), when this subject was considered, one of the members stated that he had been 'snowed in' during a previous attempt to be present at the annual session.

"Besides, the hotels are crowded, and it is difficult to obtain accommodations; the better halls for public assemblage are occupied by the Legislature, and the State Medical Society is obliged to hold its sessions in rooms which are very unfavorable for the transaction of business.

"One other consideration will be brought forward, in the language in which it was originally presented in 1870, in the inaugural address of the President, Dr. Jas. P. White, of Buffalo, to this Society:—

"'Perhaps it is inexpedient to change the time of holding the annual meeting of the Society, but we should not shut our eyes to the fact that it now occurs during the delivery of the courses of lectures in all the Medical Colleges of the State; thus rendering it exceedingly difficult, if not impossible, for the professors in these institutions to be present. Aware that this time is fixed by a law of the State, and that in many respects it is most wise that it should remain unchanged, simply remarking that it excludes the teachers in the schools, from attendance, and deprives us of their valuable assistance in our deliberations, I leave the matter, without suggestion, in your hands. The fall season presents more advantages than any other, as a time for the annual meeting. There is, as a rule, a comparatively healthy period in the latter part of September, when practitioners would find it more convenient to be absent from their patients than in the busy season of winter. Then, travel is also agreeable and easy, the hotels in Albany are not overcrowded, and there would be a better choice of rooms for assemblage.'

"Of the Medical Colleges throughout the State, but one meets before October, and that is in Albany.

"In fact this period seems peculiarly fitted to the different wants of practitioners in all parts of the State, and, without designating a special day for the annual meeting of the New York State Medical Society, until the subject has been further discussed, your committee would suggest that the day selected should be from the latter half of September.

"All of which is respectfully submitted."

S. OAKLEY VANDERPOEL.
ALEXANDER HUTCHINSON."

On motion of Dr. Eliot, the report was accepted, and the discussion of it made a special order of business for the evening session, after the reading of a report by Dr. Squibb.

DR. T. ADDIS EMMET read a paper on "Laceration of the Perineum, involving the Sphincter, and an Operation for Securing Union of the Muscle," which paper will appear in full in a subsequent number of THE MEDICAL RECORD.

DR. E. H. PARKER, of Poughkeepsie, read the history of a case of "Dislocation of the Tarsus from the Astragalus," and exhibited the specimen.

DR. E. M. MOORE, of Rochester, read a paper on "Intra-Capsular Fracture, Illustrated by Two Cases," of which he presented specimens.

DR. GURDON BUCK, in discussing the paper, stated that intra-capsular fracture of the cervix femoris was not of so unfrequent occurrence as has been supposed by many surgeons, and was by no means confined to an advanced period of life; one case in a person of twelve, and in others of from seventeen to eighteen years of age, having been recorded. An army officer, between thirty-five and thirty-six years old, had recently been treated for this injury in the Presbyterian Hospital, in New York. Dr. Buck considered that the accident invariably resulted from a fall upon the trochanter, or force applied in an analogous way, and this force may vary in degree so as to be just sufficient to fracture the bone without causing displacement, or the fragments may be impacted and displaced, and so retained by the periosteum and surrounding tissues. Any simple method of diagnosis ought to enable the surgeon to distinguish this from other fractures or dislocations. A slight survey will exclude fractures of the shaft, and the absence of abduction or adduction of the limb will exclude dislocation. The limbs will, most likely, lie parallel with each other, and there will be a loss of motion. In making a comparative measurement of the length of the limbs, the ankles should not be brought together, but the tape should be used. To show how easy it is to make a mistake in measuring by

the former method. Dr. Buck said that one of his old pupils was going with Mr. Ericsen through the wards of the latter's hospital service, and had his attention directed to a case of fracture of the femur which had about recovered, as Mr. Ericsen said, with no shortening, in proof of which the ankles were brought together. On measuring in the usual manner, however, with a tape, a considerable shortening was demonstrated to exist. If, in a supposed case of fracture, the surgeon finds more or less eversion of the foot, and inversion is arrested when the toe is in a direct line; if pain is referred to the region of the hip-joint; if there is flattening of the affected side, he may infer the existence of this fracture, and is not justified in trying to produce crepitus, as this will break up the condition of impaction which favors adhesion.

Two or three cases were related by the speaker, to show that absorption of the extremities of the bones may take place in the process of recovery, and considerable shortening may be apparent at the end of a few weeks, where none existed at the time of injury.

Dr. A. T. Douglass, of Ulster County, called attention to the fact that the two anterior superior spinous processes of the ilium may not be symmetrical, and many are thus led to error in measurement; and related an instance in which this had been the case.

Dr. A. N. Bell, of Brooklyn, mentioned a case which he thought controverted the statement made by Dr. Buck, viz: that intra-capsular fracture was *always* the result of direct violence.

A man stepped into an elevator which was not secured, and fell with him to the bottom of the shaft, a distance of about forty feet. The man maintained an erect posture until the elevator reached the bottom, and then fell. Dr. Bell believed the fracture of the cervix femoris, which resulted, to have been produced by the force transmitted through the shaft of the femur.

Dr. E. M. Hunt, delegate from the New Jersey State Medical Society, was introduced, and made a few very happy remarks.

The Secretary read an invitation from the Medical Society of the County of Albany, requesting the pleasure of meeting the members, delegates, and invited guests of the State Society, on Wednesday evening in Perry Hall, immediately after the President's address; which invitation was accepted.

The following papers were read by title, and, with the others, above enumerated, referred to the publishing committee.

"Case of Fatty Tumor of the Abdomen," and another of "Senile Hypertrophy of the Prostate Gland," by James S. Bailey, M.D. "Unusual Case of Inflammation of the Urinary Organs," by S. T. Clark, M.D.

The Society then adjourned until eight o'clock.

First Day.—Evening Session.

The Society met at the hour appointed, and was called to order by the Vice-President, Dr. B. F. Sherman, who occupied the Chair.

Dr. E. R. Squibb, of Brooklyn, chairman of the committee on the Pharmacopœia of the United States of America, then read their report, and made an exhaustive review of the last edition of the work.

The report was, on motion, accepted.

A paper, by Dr. George Douglass, on "Dropsy after Scarlatina," was read by title and referred; and the Society proceeded to discuss the suggestions made by the committee on changing the time of meeting. After an hour spent in argument in favor of the change; reading of by-laws, and explanation of the charter of the Society—during all of which it was apparent that everybody desired a change, but nobody could agree upon a time of meeting—the meeting was unanimously adjourned until the next (Wednesday) morning at nine o'clock.

Second Day.—Morning Session.

The Society met at a quarter past nine o'clock, and the meeting was opened with prayer by the President.

After the reading and adoption of the minutes of the sessions of the previous day, the Secretary, for Dr. Oliver White, chairman of the committee on by-laws, read a report, which was adopted. The Secretary also stated that he had received letters from Dr. Henry I. Bowditch, of Boston; Dr. C. E. Brown-Séquard, of New York; Dr. Wm. Brodie, of Detroit, and Dr. E. M. Snow, of Providence, R. I., all of whom regretted their inability to be present at the meetings.

Dr. Fessenden N. Otis, of New York, then read a paper on "Strictures of the Male Urethra, with Results of Operation with the Dilating Urethrotome," in which he brought prominently to the notice of the Society the fact of the dependence of gleet upon urethral stricture of large calibre, and presented a new instrument, devised by himself, for dividing such strictures.

Dr. Otis claimed that, in most cases, these strictures, by offering an obstacle to the out-flowing urine, and by retaining behind them a few drops, become a constant source of irritation to the urethra, and keep up a discharge which would otherwise cease spontaneously. The indication in such cases he thought to be clearly to completely divide the stricture and restore the urethra to its normal calibre. Having found all the instruments heretofore in use ineffectual on account of the large size of these strictures, Dr. Otis was led to devise one which combines both dilatation and incision. The main advantages claimed by the author for his instrument were:

1st. That on account of the width to which the blades can be separated, it is adapted to deal with strictures of the largest calibre, which no other instrument can divide.

2d. That by the means of its indicator, the exact seat of stricture can be determined, and only the contracted portion of the urethra divided (the blade becoming hidden as soon as it has severed the constricting bands).

3d. That as the knife is brought to bear against a tissue already made tense, the incision is more thorough and almost entirely painless.

4th. That subsequent dilatation by the use of steel sounds to prevent recurrence of the stricture is unnecessary after healing of the incision has taken place.

The author cited a number of cases upon which he had operated with the best results, and which, many months after the operation, presented no gleety discharge, nor could contraction of the urethra at any point be discovered; he insisted very forcibly upon the advantages derived from combining dilatation and incision, the cure being permanent, although subsequent dilatation by the use of steel sounds may not be resorted to; he condemned the use of the endoscope in the treatment of chronic urethral discharges, the improvement having, in his observation, proved fallacious, the disease returning readily from inappreciable causes.

For the detection of strictures of large calibre Dr. Otis gave a very decided preference to the metallic silver-plated bulbous sounds for the straight portion, and the olive-pointed bougies for the curved portion of the urethra, and dwelt very forcibly upon the in-

possibility of detecting slight constrictions with the ordinary steel sounds. He ascribed the ease with which multiple strictures of the urethra are now made out, to the improvement in the instruments at our command, and showed that, whereas contractions of the urethra at more than one point in the same individual were formerly looked upon as a rare occurrence, the latest observers have found it to exist in most cases, he himself having clearly demonstrated the presence of as many as six distinct strictures in the same urethra.

In evidence of the happy results following operations by the dilating urethrotome, Dr. Otis presented the testimony of several surgeons (Drs. Sands, Gouley, and Weir), who, at his request, examined patients operated upon a few months previously. These gentlemen found that in every case the urethra had been restored to its normal calibre, throughout.

The special advantages claimed for this method, and the instruments employed, above those of Thompson, Holt, and Maisonneuve, are, that they completely restore the urethra to its normal calibre; prevent the recurrence of close strictures, and rid the patient of the troublesome discharge and irritation resulting from them.

Drs. Gouley and Newman, of New York, made a few remarks on the subject of strictures; after which Dr. D. B. St. John Roosa arose to a question of privilege, saying that a pamphlet which had been distributed among the members since the commencement of the meeting, containing a written foot-note, charged the Medical Department of the University of New York with continually selling and issuing diplomas "to persons who are known to be of the worst possible morals, and to well known fraudulent and criminal advertisers," which was utterly false; had been so proven in every case in the columns of The Medical Record; and that he, as a *teacher* in the college, and in behalf of the council, of which he was a member, denied the truth of the statements. He wished to say, furthermore, that the author of the pamphlet had been expelled from the New York Pathological Society, for a personal attack made by him upon the president of the Society—Dr. Alfred L. Loomis, a professor in that school.

Dr. James R. Leaming, of New York, read a portion of a paper on "Plastic Exudation within the Pleura."

Dr. Charles H. Porter, Treasurer, made his annual report, which was referred to an auditing committee, appointed by the Chair,—viz: Drs. J. V. Cobb, H. Corliss, and ——Staats.

Dr. Ellsworth Eliot offered the following resolution:—

Resolved, That candidates elected to permanent membership who neglect, for one year from the date of their election, to pay the fee required by our by-laws, shall forfeit their rights as permanent members.

The resolution was amended so as to read "a year from the date of notice of their election," and so adopted.

Dr. A. N. Bell, of Brooklyn, then read the report of the committee on hygiene, consisting of a paper on the "Quarantine Establishment of New York."

Dr. Frazier, of the Committee on inviting the Governor and certain members of the Legislature to participate in the meetings of the Society, reported that they had performed the duty.

Dr. A. B. Burger, of Saratoga county, presented to the Society a kidney which had undergone cystic degeneration, and weighed about three pounds. The description of the case was referred to the publishing committee.

Dr. Wm. T. Lusk read the greater part of a paper on "The Pathology of Labor-Pains," and was followed by Dr. Gurdon Buck, who presented to the Society some plaster casts of the stages in an operation for the reconstruction of an under-lip.

The committee for auditing the Treasurer's report, reported that it had been found to be correct.

The following *Delegates* were introduced to the Society:—Dr. M. H. Eddy, of Middleburg, Vermont, delegate from the Medical Society of the State of Vermont; Dr. John J. H. Love, delegate from the New Jersey State Medical Society, and Dr. S. L. F. Simpson, of Concord, N. H.

Dr. Louis A. Sayre read a paper on "Diastasis of the Head of the Femur, and Formation of an Artificial Hip-Joint," exhibiting a specimen in illustration.

Dr. J. V. P. Quackenbush, of Albany, read a paper on "Hydrorhœa," most of which was composed of extracts from recent journals.

Dr. E. R. Squibb, of the committee on medical ethics, made the following report on the matters relating to the Niagara County Medical Society:—

"The Committee on Medical Ethics, to which was referred the question of the admission of delegates from the Niagara County Medical Society, reports, that so far as they can make out, the facts of the case are as follows:

"At a meeting of the Niagara County Medical Society, held January 3d, 1871, nine of the forty members being present, a resolution was passed declaring the Society disbanded. Immediately thereafter, these members organized themselves into a new Society, bearing the same name and under the same officers. The reason alleged for this action was, that under the old organization it was not possible to enforce discipline among the members. The delegates named by this self-constituted body presented themselves for admission into this Society at the meeting of February of 1871. At the same time a protest, signed by Doctors Taylor, Fasset, and others, against the recognition of this new organization, was presented. The following report was finally made by the Committee on Medical Ethics, to which the matter had been referred, and was adopted by the Society (p. 79, 1871).

"At a meeting held June, 1871, they did reorganize, in accordance with the recommendation, and adopted a constitution and by-laws which had been submitted to Dr. White, as Chairman of the Committee on By-laws, and approved by him.

"They therefore claim to be truly the Niagara County Medical Society; constituted according to the recommendation of the Society; subsequently recognized by it in various ways, and entitled to representation.

"It is claimed, however, by a number of the original members of the Society, that the reorganization is rendered invalid by the action of the President, who subsequently declared under oath, as President, that the Niagara County Medical Society was organized in 1871, and that the Society organized in 1823 was disbanded in 1871; that they were a new society, and totally repudiated the old organization.

"Acting on this assumption, they issued a call for a meeting of the members of the Niagara County Medical Society, and at this meeting, held the first Tuesday in June, 1872, elected a President and other officers, and now ask recognition of the Society.

"Without entering into an argument which would consume too much of the valuable time of this Society, your committee will merely state the conclusions at which they have arrived.

"The act of disbanding the Society was null and void,

"That in acting under the advice of this Society in June, 1871, the Medical Society of Niagara County of 1823 was again in full operation.

"That although we think Dr. Clark was in error in stating that the Society dated from 1871, and not 1823, yet this statement could not render the previous proceedings invalid. We therefore propose the following resolution:

"*Resolved*, That this Society recognizes the organization in Niagara County, of which A. G. Skinner is now President, and J. B. Buchner, Secretary, as the Niagara County Medical Society, and will receive Rexford Davidson and Charles N. Palmer, delegates regularly appointed by said Society."

THOMAS HUN,
Chairman of Committee on Ethics.

Albany, Feb. 5th, 1873.

The report was unanimously adopted.

DR. A. VANDERVEER presented an obituary of Dr. P. Van Olinda, which was read by title and referred to the publishing committee.

The Society then took a recess until 2.30 P.M.

SECOND DAY.—AFTERNOON SESSION.

The meeting being called to order by the President, the following delegates made their reports:—

Dr. Douglass, delegate to the Connecticut State Medical Society.

Dr. Corliss, delegate to the Maine Medical Association.

Dr. Newman, delegate to the New Jersey State Medical Society.

DR. A. JACOBI, of the committee on foundling asylums, which was continued from the previous year, made the final report, and DR. JOEL FOSTER, who was last year added to the committee, read a minority report. The former was accepted by the Society, and adopted as an expression of their views on the subject.

DR. KENDALL, of Baldwinsville, offered the following:—

Resolved, That the By-Laws of this Society be altered, so that section eleven, of paragraph three, shall read as follows:—

¶ 3, § 11. At the annual meeting, at the close of the morning of the first day, the members of the Society shall be organized into eight committees, by Senatorial districts, as established by the law of 1836, the members present from each district constituting one committee, each of which shall elect one member; the members thus elected, with one appointed by the President, as chairman, shall constitute the committee on nominations.

On motion by himself, it was laid on the table for future discussion.

DR. STORCK, of Erie County, offered the following resolution:—

Resolved, That the bill entitled "An Act relative to the Medical Laws of the State of New York," passed by both houses of the Legislature of last year, but vetoed by Governor Hoffman, meets with the approval of this Society.

Resolved, That a committee of three be appointed by the Chair to take all necessary steps to secure the passage of said act by the Legislature during its present session.

DR. STORCK hoped the bill might be made a law, as in his section of the country there was urgent necessity for protection against the practices of unprincipled quacks.

DR. VANDERPOEL said:—"I scarcely know the points of this law, but on general principles I am opposed to this species of legislation. I think the less the Legislature bother with our diplomas, and the less we throw ourselves upon their protection, the better for our profession. I have never yet seen the time when men who were well educated in their profession, and who appreciated fully the responsibilities and duties conferred upon them, have not had the confidence of the public; and you generally find that the class of people who throw themselves upon the protection of the Legislature, are the very weak brethren in the profession. I do not care whether I have a parchment or not. If I cannot demand compensation for my services because of their value, I would rather sink than throw myself behind the barrier of a legislative enactment. We went through this very thing twenty years ago—there is not one here but knows it—the Legislature abolished all these barriers; and I should be very sorry to see a retrograde movement in this respect." [Applause.]

DR. SQUIBB remarked:—"There is another point of view which I beg to throw out. There is a certain class in the community who will employ quacks, and we cannot control them. We know that in the case of abortionists the more secret they are, the better is their practice. Quacks cannot be brought within legislative control unless our police establishments are made very much more effective than they ever have been. I think medicine must police itself and legislate for itself; and I think its only safety lies in its so doing."

DR. E. M. MOORE said:—The gentleman from Buffalo is probably unaware of the stage we have passed through, as Dr. Vanderpoel has just said. I think it was in the year 1844,—it sounds a good way back,—I was the youngest member of a committee of three, to petition the Legislature to abolish the laws for the purpose of enabling physicians to collect fees for medical services. We did this just at that time, with one of our members in the Senate of the State, for the purpose of getting rid of one of the most vexatious, pestilential set of wretched quacks, that it has ever been my misfortune to come in contact with. They were making a handle of the fact that we had the power to go on and practise, and collect our fees, while they could not; and for that reason all their fees must be paid in advance. And, of course, it was so specious a thing that no argument could be brought against it; and we felt the annoyance of it so much as to request the Legislature to abolish the law; and we have never regretted doing it. It was undoubtedly a good move, and if we could cut free from the Legislature entirely, I should be satisfied. For that reason, Mr. President, I think that we should not entertain any such project whatsoever—give it the go-by.

"Again, I will remind the gentleman, whom I recognize to be a German—indeed he alludes to the fact that he is a German—that some of the most outrageous quacks have come from Germany—homeopathy, hydropathy, and mesmerism. Now there is no mind at present, upon the face of this planet, that controls human thought more perfectly than the German mind; it is really in advance of the world, but it also, sometimes, seems to take long strides in queer directions; and we must recollect also that there is no country in the world where the business of legislating exactly how a man shall go to bed; and how he shall get up; how he shall eat his breakfast; how he shall do everything, is carried to such perfection as it is in Germany. And just through all this, and in spite of it, these things have grown up and have been transplanted into this country, and now we are suffering from them; and

therefore the poorest remedy we can have will be from the Legislature of the State of New York. [Applause.]

On motion, the resolutions were laid on the table.

Dr. Robert Newman offered the following:—

Resolved, That when we adjourn, we adjourn this annual meeting to the fourth Tuesday in September, for the transaction of executive business.

Resolved, That after this year the annual meeting be held at Albany, on the fourth Tuesday in September.

Resolved, That the Secretary be authorized to make this amendment of the by-laws legal, if legislation is required.

The discussion of the previous evening was, in part, repeated; but finally a motion was carried which laid the whole subject on the table.

Dr. B. L. Hovey read a report of five cases of Colles' fracture.

Dr. J. P. Gray exhibited twenty micro-photographs of diseased brain tissue, made under the supervision of Dr. Hun, the pathologist of the Utica asylum.

Dr. H. Knapp made some remarks on the subject of "Hemiopic and Sector-like Defects of the Field of Vision, and their Connection with Diseases of the Heart and Brain," illustrating it with diagrams.

Dr. J. P. Palmer, of Ontario County, read a paper on Spotted Fever.

Dr. Corliss read a biography of Dr. Barent P. Staats, of Albany.

The following papers were read by title, and referred to the publishing committee; as were the others above mentioned:—

"Three Cases of Abscess and Pelvic Peritonitis, from Ulceration of the Appendix Vermiformis, relieved by Operation," by Dr. R. B. Bontecou, of Troy. "Complete Dislocation of the Fourth Dorsal Vertebra, Forwards," by Dr. Graves, of Steuben County. "On the Use of Atropine in some Diseases of the Eye," by Dr. Edwin Hutchinson, of Utica.

Dr. Babcock reported that the Censors of the Eastern District had examined E. V. Stryker; found him well qualified to practise medicine, and recommended him as a proper person to receive a diploma from the Society.

The meeting then adjourned until eight o'clock, when the Society met in the Assembly chamber to listen to the President's address.

Following the address the members, delegates, and invited guests were received in Perry Hall by the Medical Society of the County of Albany, where an address was delivered by Mr. W. H. Bogart, correspondent of the *World*, and the company partook of a very elegant supper.

THIRD DAY.—MORNING SESSION.

The President called the meeting to order at 9.30 A.M., and a prayer was offered by the Rev. Mr. Reeves: after which the minutes were read and approved.

Dr. Vanderpoel, chairman of the committee on the President's address, reported at length upon the suggestions made in the latter, and presented to the Society a number of resolutions—in substance as follows:—

1st. Advocating the construction of a State Hospital for Epileptics.

2d. Authorizing the appointment of a committee of three to secure legislation for this object.

3d. Recommending the appointment by the board of regents of the university of the State of New York, of a board of examiners for the purpose of determining the fitness of candidates for the degree of doctor in medicine, according to an Act passed in 1872.

4th. Making the board consist of nine members, of whom the President of the Society would be one,—*ex-officio*.

5th. Directing the Secretary to urge upon county societies the formation of committees on hygiene.

6th. Recommending the appointment of a committee of three to confer with the committees of other State societies, with a view to improving the organization of the American Medical Association.

7th. Directing that the medical colleges of the State be made acquainted with the views of the Society regarding the necessity for changes in their mode of instruction.

On motion of the Chairman of the business committee, the discussion of the paper was postponed to allow Dr. Robinson to read a paper entitled "Cases in Practice;" after which Dr. E. M. Moore called attention to the law above referred to, which was passed through the Legislature by the influence, it is claimed, of the homœopathic physicians of the State, and which will be found in another part of this Journal. Dr. Moore advocated the immediate nomination by the Society, of the board of examiners.

Dr. Eliot objected, on the ground that unless examination by such a board was to be made compulsory, and the examiners paid for their services, nothing whatever would be accomplished in the way of medical reform, by such a measure.

Dr. Moore said he had reason to believe that no difficulty would be experienced in finding gentlemen who would take the positions, since there is little prospect of their duties being more than nominal; and there were several reasons, which he explained, why it was desirable that the Society should comply at once with the provisions of the Act.

Dr. J. Marion Sims read the history of "A Case of Enucleation and Removal of an Uterine Fibroid Tumor," and exhibited the tumor and a trowel-shaped instrument which had been used in the operation. The tumor had been attached to the fundus, anterior and posterior surfaces of the uterine cavity, the greatest space being in front. It was removed without difficulty after dilatation of the cervix had been accomplished, and was followed by recovery on the part of the patient.

Dr. William C. Wey read a paper entitled, "Some Observations concerning the Hypodermic Injection of Ergot in Uterine Fibroids," in which he confirmed the statements of Hildebrandt regarding the remarkable results following the use of this remedy. He had, however, so little success with ergotine; the nauseating effects resulting from the prolonged use of ergot when taken into the stomach, had been so constant; its injection hypodermically had caused so much local irritation, that he had, with the assistance of Dr. Squibb, tried the introduction of suppositories containing a concentrated extract of ergot, and from this mode of its employment had derived the most favorable results.

Dr. Sims, who had been in pretty constant communication with Drs. Wey and Squibb about the case, confirmed the statements of the former regarding the value of ergot when used in the manner last mentioned.

Dr. Squibb made some lengthy and very interesting remarks regarding the nature of the remedy and the mode of its preparation; saying, among other things, that ergotine was a very variable substance, and by no means represented the active principles of the drug; containing more or less of them, according to the method employed for its extraction, and being un-

worthy of attention from those who wish to produce the effects of ergot itself.

The value of the extract depends entirely upon the care taken in selecting the drug, and Dr. Squibb had found by experience that the simplest mode of making it was the best; and after going through all the complicated processes, is now satisfied that evaporation of the watery extract on dinner-plates, stirring it carefully, and limiting the temperature to which it can be exposed, is the best way to obtain the concentrated extract, mentioned by Drs. Wey and Sims. At one time he thought the addition of glycerine necessary, but has found that the extract possesses hygrometric properties and does not, as he anticipated, become, with keeping, too dry for use.

Dr. J. N. Northrop, of Albany, presented to the Society, a child who had a congenital loss of the right arm, from below the middle. The father of the child had received a gun-shot injury of the right arm, and the scars were apparent just above a point corresponding to the extremity of the child's stump. During the time the mother of the child was carrying him *in utero* the father suffered from neuralgic pains in the arm, and the mother was in the habit of rubbing the arm and shoulder to give him relief. Dr. Northrop attributed the malformation of the child to "maternal impression," and called the case one of congenital amputation.

Dr. A. Jacobi said that this differed from what was known as congenital amputation, inasmuch as the latter has been supposed to depend upon the presence of constricting bands, which cut off circulation from a member, and so lead to its death. The present case was one of arrest of development; in proof of which Dr. Jacobi referred to the presence of little prominences at the extremity of the stump, resembling the "sixth finger," which every surgeon has had occasion to cut off. These little growths he believed to be of this nature, and to represent the fingers of a hand and fore-arm which had never been developed.

The following papers were read by title. "Penetrating Gun-shot wounds of Cranium, with Recovery," by Dr. A. Vanderveer.

"Sequelæ of a Case of Purpura Hemorrhagica," by Dr. H. S. Crandall.

Dr. C. Devoe presented two pathological specimens, and, owing to the limited time, made no remarks.

Dr. A. N. Bell offered the following resolution, which was added to the report of the committee on the President's address, and the whole accepted and adopted:—

Resolved, That the standing Committee on Hygiene be added to, and hereafter be recognized among the standing committees, under § 3, p. 20, of the Organization and By-laws of the Society, and that said committee place itself in immediate correspondence with the county societies.

Resolved, That the Committee on Hygiene consist of seven members, one of whom shall be Dr. C. R. Agnew; the balance of the committee to be appointed by the Chair.

The President then appointed the committee, as follows:—Drs. A. N. Bell, S. O. Vanderpoel, H. D. Didama, W. H. Dean, John Ordronaux, Stephen Smith, and C. R. Agnew.

The Nominating Committee then reported through J. Foster Jenkins, their Secretary, as follows:—The Committee on Nominations have the honor to report that they have unanimously agreed to recommend to the Society the following nominations to office for the ensuing year:—

President—Dr. E. M. Moore, of Rochester.
Vice-President—Dr. Francis Burdick, of Johnstown.
Secretary—Dr. William H. Bailey, of Albany.
Treasurer—Dr. Charles H. Porter, of Albany.

CENSORS.

Southern District—Drs. E. R. Squibb, of Brooklyn; E. H. Parker, of Poughkeepsie; Ellsworth Eliot, of New York.

Eastern District—Drs. J. P. Sharer, of Herkimer; Jas. L. Babcock, of Albany; George H. Hubbard, of Lansingburg.

Middle District—Drs. M. M. Bagg, of Utica; Horace Lathrop, of Cooperstown; C. G. Bacon, of Fulton.

Western District—Drs. Caleb Green, of Homer; C. C. Wyckoff, of Buffalo; D. Colvin, of Clyde.

COMMITTEE ON CORRESPONDENCE.

1*st District*—Dr. George F. Shrady, of Barrytown.
2*d District*—Dr. Abraham Crispell, of Rondout.
3*d District*—Dr. Henry B. Whitton, of Troy.
4*th District*—Dr. T. B. Reynolds, of Saratoga.
5*th District*—Dr. Samuel G. Wolcott, of Utica.
6*th District*—Dr. J. G. Orton, of Binghamton, (Chairman.)
7*th District*—Dr. Harvey Wilbur, of Syracuse.
8*th District*—Dr. Thos. F. Rochester, of Buffalo.

AS PERMANENT MEMBERS.

1*st District*—Drs. Robert Newman, of New York; J. Marion Sims, of New York.
2*d District*—Drs. T. Blanch Smith, of Rockland; Wm. H. Helm, of Westchester.
3*d District*—Drs. E. R. Hun, of Albany; R. H. Worrel, of Rensselaer.
4*th District*—Drs. John Parr, of Montgomery; D. G. Dodge, of Clinton.
5*th District*—Drs. H. G. P. Spencer, of Jefferson; Wm. L. Baldwin, of Oneida.
6*th District*—Drs. J. S. Dolson, of Steuben; William Fitch, of Tompkins.
7*th District*—Drs. Geo. W. Earle, of Onondaga; E. W. Simmons, of Ontario.
8*th District*—Drs. C. N. Palmer, of Niagara; J. R. Choate, of Genesee.

AS ELIGIBLE FOR PERMANENT MEMBERSHIP.

1*st District*—Drs. Ernst Krackowizer, A. Jacobi, H. Knapp, B. S. Thompson, and S. Caro, of New York.
2*d District*—Drs. Augustus Kühn, of Ulster, and Sol. Van Etten, of Oswego.
3*d District*—Drs. Albert Vanderveer, Henry March, and Charles A. Robertson, of Albany, and A. M. Vedder, of Schenectady.
4*th District*—Drs. Norman L. Snow, of Montgomery; Eugene Beach, of Fulton; E. D. Ferguson, of Essex; and A. C. Butcher, of Clinton.
5*th District*—Drs. Frank D. Beebe, and Lucius Stevens, of Oswego; F. B. A. Lewis, of Jefferson; F. B. Hough, of ———; Wm. H. Nelson and Judson B. Andrews, of Oneida.
6*th. District*—Drs. George Douglas, of Chenango; W. B. Alley, of Livingston; A. H. Cruttenden, of Steuben; J. K. Stanchfield, of Chemung, and G. W. Metcalf, of Tioga.
7*th District*—Drs. J. W. Palmer, of Ontario; T. B. S. Brinkerhoff, of Cayuga, and Wm. Oliver, of Yates.
8*th District*—Drs. Wm. B. Sprague, of Genesee; Wm. S. Ely, of Monroe; Wm. Gould, of Erie, and B. L. Hovey.

AS HONORARY MEMBERS.

Prof. Robert Stokes, Dublin; Prof. Rawdon McNamara, Dublin; J. M. Toner, Washington, D. C.; H. C. Lombard, Geneva, Switzerland.

AS ELIGIBLE TO HONORARY MEMBERSHIP.

Ernest Hart, London; Benj. W. Richardson, London; Spencer Wells, London; S. C. Bussey, Washington, D. C.; E. H. Gregory, St. Louis, Mo.; Washington L. Atlee, Philadelphia, Pa.; C. E. Brown-Séquard, New York; Ezra M. Hunt, Metuchen, N. J.; J. Mathews Duncan, Edinburgh.

FOR HONORARY DEGREE OF DOCTOR OF MEDICINE.

Matthew R. Teft, Onondaga Hill, Onondaga Co.

DELEGATES

AMERICAN MEDICAL ASSOCIATION.

Drs. Frederick Hyde, H. W. Deane, C. B. Coventry, C. R. Agnew, E. M. Moore, T. F. Rochester, Ernst Krackowizer, G. J. Fisher, A. Jacobi, P. Stewart, H. N. Eastman, B. F. Sherman, T. A. Emmet, Robt. Newman, S. O. Vanderpool, John P. Gray, D. P. Bissell, H. D. Didama, J. V. P. Quackenbush, E. R. Squibb, Francis Burdick, W. H. Bailey, C. C. Wyckoff, Alex. Hutchins, W. D. Strong, J. W. Wilkie, Wm. M. Chamberlain, J. R. Leaming and B. D. Hovey.

PENNSYLVANIA.

Drs. Jas. B. Murdock, S. Caro, J. B. Graves, S. H. French and C. E. Rider.

OHIO.

Drs. C. C. G. Gray and W. W. Townsend.

RHODE ISLAND.

Drs. B. S. Thompson and Samuel Hart.

NEW JERSEY.

Drs. E. R. Hun, M. H. Burton, R. L. Allen and Morgan Snyder.

NEW HAMPSHIRE.

Drs. R. H. Ward, James Anderson, Geo. H. Purdy, and M. R. Colvy.

VERMONT.

Drs. W. W. Porter, J. V. Cobb, P. Failing, Thompson Burton, F. C. Butler and H. C. Husted.

KENTUCKY.

Dr. Rexford Davidson.

KANSAS.

Dr. Hiram McNutt.

MAINE.

Drs. E. R. Peaslee, Wm. Govan, D. B. St. John Roosa and John Swinburne.

ILLINOIS.

Drs. J. H. Armsby and G. S. Winston.

MASSACHUSETTS.

Drs. E. Harris, John C. Peters, J. V. P. Quackenbush, J. V. Kendall, Gurdon Buck and Geo. F. Shrady.

CONNECTICUT.

Drs. J. C. Hutchinson, C. M. Palmer, H. C. Hendrick, A. E. M. Purdy, Ferris Jacobs, W. T. Douglas and S. G. Wolcott.

CANADIAN MEDICAL SOCIETY.

Dr. A. S. Wolf.

COMMITTEE ON STATISTICS.

First Dist.: H. P. Farnham, New York. *Second Dist.*: G. J. Fisher, Sing Sing. *Third Dist.*: Chas. H. Porter, Albany. *Fourth Dist.*: Alex. M. Vedder, Schenectady. *Fifth Dist.*: A. S. Odell, Brookfield, Madison Co. *Sixth Dist.*: J. G. Orton, Binghamton. *Seventh Dist.*: Nelson Niverson, Hector, Schuyler Co. *Eighth Dist.*: S. B. Coates, Batavia.

COMMITTEE ON PRIZE ESSAYS.

Drs. Thomas S. Rochester, Buffalo; Henry Dean, Rochester; Sanford Eastman, Buffalo.

COMMITTEE ON PUBLICATION.

Drs. H. B. Wheton, J. V. P. Quackenbush, W. H. Bailey.

COMMITTEE ON BY-LAWS.

Drs. Oliver White, New York; Thomas Hun, Albany; W. H. Bailey, Albany.

CENSOR FOR SYRACUSE UNIVERSITY, MED. DEP.

Dr. Sam'l G. Wolcott.

COMMITTEE ON PHARMACOLOGY.

Drs. E. R. Squibb, Caleb Green, Wm. Manlius Smith and B. A. Segur.

On motion of Dr. Eliot, the Vice-President was empowered to cast the ballot for the Society, and Drs. Moore, Burdick, Bailey, and Porter being respectively declared elected, the report of the Committee was accepted as a whole, and the officers named by them declared unanimously elected.

DR. JENKINS offered a resolution, as a part of the report of the committee, that no one should be eligible for election to permanent membership until he had been a delegate for three years.

DR. SQUIBB offered an amendment, which required delegates to be present and serve at the meetings of the Society for three years (not necessarily consecutive).

After discussion, the resolution was carried as amended, and the report of the committee adopted.

DR. F. B. A. LEWIS offered the following:

Resolved, That this Society extend their sincere thanks to the officers and members of the Medical Society of the County of Albany, for their munificent entertainment and warm reception of last evening. Carried.

The PRESIDENT addressing the Society, then said:

I cannot leave the chair in which I have been placed by your favor, without thanking you for the great indulgence and charity which you have manifested towards me, as your chairman, nor without wishing you, personally and collectively, all the happiness that you desire in your individual relations, and in your professional associations. I thank you for your great kindness. [Applause.]

On motion of Dr. Ellsworth Eliot, the Society adjourned, *sine die*.

Progress of Medical Science.

SULPHATE OF CINCHONA.—M. Briquet, at a recent meeting of the Paris Academy of Medicine, gave his conclusions with regard to the value of this drug, as based upon 893 authenticated cases which had been treated successfully with it, since the time of Magendie and Chomel.

Its success had been especially marked in cases of intermittent fever of medium intensity. Furthermore, it arrests the paroxysms of typhoid, mitigates the symptoms of intermittent neuralgia, and is of great benefit in articular rheumatism. Dr. Briquet lays great stress upon the mode of administering the drug. It should be given in watery solution in doses of from fifty *centigrammes* to one *gramme* (eight to fifteen grains), according to the intensity of the fever. The whole dose must not be given at once, but must be divided over five or six hours, and it is extremely important that the substance should be taken during the apyretic interval, and at least eight or ten hours before the return of the fit.

The Art of Tinting Opacities of the Cornea.—At the last meeting of the British Medical Association, Dr. C. B. Taylor, of Nottingham, spoke of a method by which this deformity might in some cases be lessened. By means of fine needles, or an instrument made for the purpose, the diseased cornea may be tattooed with India ink, and various other substances, so as to be distinguished from the neighboring black pupil. Not only is the deformity thus removed, but, it is said, the sight is somewhat improved, which is somewhat difficult of comprehension. The method is almost painless, free from danger, and easy of execution. When nearly the whole of the cornea is opaque, it is easy to restore the natural appearance by tattooing a central black pupil; and, after iridectomy, extraction of cataract, &c., the dazzling, if excessive, may be limited by tinting a portion of the cornea so as to constitute a permanent shade. It is not necessary to confine the patients or close the eye. Where a solution of lamp-black and nitrate of silver is employed, one sitting suffices. The opacities should be tattooed obliquely, beginning from below.

Treatment of Phagedenic Chancre by Irrigation.—In the treatment of phagedenic chancres, Mr. Hutchinson, of the London Hospital, has for some time, with very good success, used the continuous bath. The patient is ordered to sit in a hip-bath with tepid water for the greater part of the twenty-four hours, a few hours being allowed for sleep. The water is changed as often as it becomes uncomfortably cool. This treatment is kept up until all phagedenic action ceases, and the sore shows a perfectly healthy surface. It may or may not be necessary to apply nitric acid to the sore in addition to the bath, but the cleansing effect is, in some cases, all that is required.

Mr. Hutchinson attaches great importance to a frequent change of the water in contact with the sore, and lately he has directed the patient to keep a continuous stream of water from an irrigating apparatus playing on the ulcerated surface, while in the hip-bath. By this means every particle of contagious phagedemic discharge is removed as soon as secreted, and the formation of a healthy surface is much accelerated.—*Boston Medical Journal.*

The Resuscitation of Animation in Newly-Born Children.—Dr. John Gregory, of Manchester, England, calls attention to two opposite conditions which he has found to exist in cases of suspended animation in the newly-born. In the first class the head appears to suffer from a redundancy of blood; and is most common when the head is born some time before the remainder of the body, and the pressure upon the portion remaining in the uterus and the vagina causes an accumulation of blood to take place in the head. This variety is generally relieved by allowing a small quantity of blood to flow from the navel. The second variety is less commonly noticed, and is that in which the reverse takes place. In a breech presentation the head, being born last, is subjected to pressure which empties its vessels and produces anæmia of the nerve-centres of the brain and medulla. Such cases are quickly relieved by placing the child's head downwards, by which posture the return of the blood to the cranium is encouraged. It is his practice in the latter class of cases to allow the infant to hang head downward for about a minute at a time, and employ also friction of the back and nucha. In both varieties the postponement of respiratory movements is attributed by him to disturbance of the circulation in the medulla.—*The Doctor.*

Psoriasis and Eczema.—In the *Annales de Dermatologie et de Siphilographie* there is an interesting article on the treatment of the dartrous diathesis. The two incarnations of dartre are psoriasis and eczema. Psoriasis is a primitive lesion of the epithelial tegumentary tissue, with a secondary, and a slight effect on the connective tissue. The glandular, vascular, and nervous apparatus escape almost completely from this lesion. Impetigo, lichen, psoriasis, both *alba* and *rubra*, are nothing more than varieties of eczema. Eczema is a dermatitis, most frequently serous; it is a primitive lesion of the connective tissue, with a secondary effect on the epithelial. The vessels are attacked in eczema, hence its diffusive character; psoriasis very rarely touches them, hence its limitation. Eczema also attacks the glands. Therefore the perspiration is diminished, and a reaction on the entire organism is possible. Psoriasis can be cured by the administration of sulphur or arsenic, because these stimulate the epithelial region, from which they are thrown out of the system. But these remedies have little or no effect on eczema, because they do not affect the connective tissue. Nothing but palliatives has been discovered up to the present for the latter malady.—*Ibid.*

Cerebria.—Charles Elam, M.D., London, in a work on "Cerebria and other Diseases of the Brain," gives an account of a disease which he has denominated Cerebria, being a spontaneous, acute, general inflammation of the substance of the brain, unaccompanied with meningitis. It is a disease which *may perhaps* occur at any period of life, although he has never seen it before eight, nor after thirty-six years of age. It is certainly much more frequent between ten and thirty than at any other ages, and is uniform in its commencement and its termination. It begins with vomiting, and ends with death. The intermediate phenomena are not very striking, and the duration is from thirty-six hours to twelve days. It differs from the forms of encephalitis hitherto described in its causation, mode of invasion, progress, and its morbid anatomy. Cases are related illustrating the natural history, etc., of this disease.

Congenital Cyst of the Neck.—In reading a thesis of M. Paul Boucher, entitled "*Etude sur les Kystes Congénitaux du Cou*," Dr. W. C. B. Fifield, of Dorchester, Mass. (*Boston Med. and Surg. Jour.*, Nov. 7, 1872), states that his recollection reverted to a case of congenital cyst of the neck occurring in his own practice, an account of which was published in 1860. The case presented some points that invalidate M. Boucher's plan of diagnosis, and was unique in the extension of the cyst to the axilla. The opinions of both Dr. Fifield and Boucher are, that any operation is unadvisable, both for simple and composite cysts. The former case conflicted with the diagnosis of M. Boucher in several particulars. 1st. Simple congenital cysts may

appear in the posterior region of the neck. 2d. They may exceed the boundaries given by M. Boucher, and appear in the axilla. 3d. Contrary to the proposition of M. Boucher and Herr Wernher, a posterior cyst may be found in a child born at term and presenting no deformity of body. Lastly, the result shows the good effects of an expectant mode of treatment.

Fibroid Tumors of the Uterus.—Alfred Meadows, M. D., London, England (*Am. Jour. Obstetrics*), in his "Remarks on the Diagnosis and Surgical Treatment of Fibroid Tumors of the Uterus," says that, having determined the situation of the tumor and its interstitial character, one is justified in attempting the removal of these tumors even though they be not intra-uterine or submucous, but are situated in the substance of the uterus itself, provided a proper canal be inaugurated. His plan is, first of all, to prepare the passages for the expulsion of the growth, and, secondly, to detach the tumor from as much of its surroundings as possible, so that, by making of it a foreign body, nature may aid in its removal, as she would in the case of a dead fœtus or a mole-pregnancy, or even a uterine polypus. Lastly, when nature has been given fair play, the écraseur should come to the rescue, and remove at once what might otherwise be the work of many months or years. He had recently under his care a case in which the tumor was completely embedded in the substance of the uterus, so much so that the os was not dilated in the very least, and he had the satisfaction, after three or four operations, of completely removing the tumor, which was of the size of a small cocoa-nut. The patient is now perfectly well.

At the date of writing he had two other cases of the same kind, but in both the tumor was much larger. He had commenced with the same plan of treatment in these cases, and he had every reason to believe that a cure would be effected.

The first step in the process is to prepare the passages for the removal of the tumor. For this purpose he recommends free division of the cervix uteri in one or more directions. The next step is breaking with the finger through the capsule, and little by little detaching the tumor from its bed. During the intervals efforts should be made, by the administration of ergot, borax, cinnamon, and other so-called oxytoxics, to secure contraction of the uterus, so as to favor nature's method of expulsion. Galvanism is also another agent of great power in this respect; and a firm bandage is of service in cases where the tumor is large and projects well into the abdominal cavity.

After-Treatment of Fibroid Tumors of the Uterus.—After the removal of these tumors, Dr. Alfred Meadows, of London, England (*Am. Jour. Obstetrics*, Aug., 1872), advocates the subjoined after-treatment: The first thing to do is to secure firm contraction of the uterus after it is emptied of its contents. This is necessary not only to prevent hemorrhage, but also to avert the occurrence of septicæmia. The latter object will be still further secured by frequent injections of warm solutions of permanganate of potash, carried well up into the uterine cavity. In reference to medicines, he knows of none which are either useful or desirable, except it be opium, and this he regards as of a greater value than any or all other medicines put together. He is also very partial to the employment of hot linseed and laudanized poultices to the abdomen in all cases of serious operations upon the uterus where there is a liability to pelvic or peritoneal inflammation.

The Brownian or Molecular Movement.—This movement, defined as a peculiar oscillatory motion, attended with little or no change of place, and common to all bodies sufficiently comminuted to admit it, is clearly demonstrated by James Tyson, M.D., of Philadelphia (*Dental Times*, Oct., 1872), by rubbing up with water any light substance like carmine, indigo, or gamboge, or any substance already finely comminuted, as the ashes from a grate, commingled thoroughly with water; a drop of this mixture is placed on a glass slide, covered with a thin glass cover, and examined. To one unaccustomed to working with the microscope, it is not at first easy to detect it, but a little examination will enable it to be seen, and, once discovered, it is readily detected in succeeding instances. It is also seen in all fluids of the animal body which contain finely comminuted particles, whatever their source. The little particles of fatty matter constituting the "molecular base" of chyle show it beautifully. The author has no doubt but that the oscillatory motion of the granules in the so-called salivary corpuscle, the pus, mucus, and white blood-corpuscle, are identical in nature, whatever the cause. But the oscillatory motion peculiar to the well-known organisms called vibrios, which appear so promptly in all animal and vegetable infusions, must not be mistaken for it, since the motion of the vibrio is attended with change of place, and molecular motion is not.

The exact cause of this peculiar motion is as imperfectly known now as when it was first noticed. That evaporation, once suggested as a cause, has nothing to do with it, is easily proved by cementing down the thin glass cover of a preparation in which it is taking place. Though heat accelerates it, it is by no means a cause of its existence; and the most that can be said with regard to it is, that it is due to some physical action rather than chemical, perhaps, taking place between the particles and the fluid in which it floats, and which is increased by heat.

Acute Traumatic Phlebitis.—J. L. Teed, M.D., Kansas City, Mo. (*Kansas City Med. Jour.*, Oct., 1872), reports the case of a young man, aged 17 years, with acute traumatic phlebitis following severe contusions, treated successfully by carbonate of ammonia in large doses. This patient took thirty grains of carbonate of ammonia every two hours, for sixty hours; then every four, for thirty-six hours; making in all nineteen drachms in ninety-six hours, together with three drachms of quinine. The dangerous symptoms were at once arrested, and befinally entirely recovered. The inflammation had passed up the deep veins, and was descending along the long saphenous vein.

Muscular Contraction a Cause of Fracture.—Geo. W. Norris, M.D., Clinical Surgical Recorder in the University Hospital, Baltimore, Md. (*Rich. & Louis. Med. Jour.*), relates a case of simple fracture of the middle third of the humerus in a mechanic, aged 32 years, caused by violent muscular contraction while throwing a brickbat.

Dr. E. S. Gaillard remarks that Prof. J. M. Holloway recently presented to the class in the Louisville Medical College a case of fracture of the clavicle, caused by throwing an ear of corn.

Ergotine as a Hemostatic.—C. H. Boardman, M.D., St. Paul, Minn. (*Northwestern Med. and Surg. Jour.*, Nov., 1872), speaks highly of ergotine, hypodermically given, in an obstinate case of placenta prævia, after all other remedies had failed. For a period of two weeks, the perils incident to this grave condition were averted, and the patient brought safely to within a fortnight of her full time.

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, February 15, 1873.

HOW SHALL WE REFORM THE AMERICAN MEDICAL ASSOCIATION?

A FEW months since we pointed out what appeared to us to be the reasons why the American Medical Association failed to represent American medical science, and we offered some suggestions to remedy the evil.

The object of our editorial has been, in part, already accomplished. The journals all over the country have been aroused to the discussion of the subject; our remarks, pungent and severe as they were, have been pronounced in the main just, true, and necessary, bringing words of encouragement from every direction.

While the journals differ in their plans for improving the Association, all agree that the Association as now carried on does not represent American science, and the best men in the profession everywhere seem to be anxious that something should be done to redeem ourselves before the world.

The radical and original proposition made by the *Boston Medical and Surgical Journal*—already published by us—does not meet our approval. Before we attempt to overthrow the present Association, let us make one careful, earnest, determined, and united effort to bring it up to the requirements of the nineteenth century.

We have been especially interested in the admirable series of papers written by Dr. N. S. Davis, of Chicago, and published by him editorially in the *Chicago Medical Examiner*. No other man knows the Association better than he; no other man can help on the work of reformation and rejuvenation so well as he. Although he modestly denies the soft impeachment, his influence at the meetings of the Association is paramount. He promises to do all in his power to correct the evils of which we complain, and we believe him to be sincere. He asks our co-operation, and he shall have it.

The suggestions we have to make may be comprised in the following propositions:—

I. Let the Committee on Ethics be chosen by the Nominating Committee, and be at least fifteen in number. So long as the Association retains its present constitution, the important business—the test questions—those which try the patience and wisdom of our profession, must first come before this committee. Let this committee carefully consider every ethical question before presenting it to the Association; let them make a majority and minority report, if necessary, so that the Association can see the true issue at stake, and, without the usual long discussion, decide one way or the other. If the committee be large and of such a character as to command the confidence of the profession, their unanimous decision will be entitled to respect, and will command it. As the committee now stands, no one respects it or believes in it. The reputation of Cæsar's wife is of little moment in comparison with the reputation of our profession—it should be far above the suspicion of carrying on important business through packed committees. Let the committee be composed of young and old men; let it represent all sections; let it include physicians and surgeons, and specialists as well as general practitioners. Whatever else we may do, reform must begin here. Will Dr. Davis have the kindness to present this matter at the next meeting of the Association?

II. Keep newspaper reporters out, and let the Association have its own reports printed daily, as Dr. Davis suggests, for the use of the members.

III. Let the papers that are read before the sections be recommended for publication in some journal, if they be worthy of such recommendation; and let the Transactions be confined to the minutes of the meetings and official reports in a condensed form for future reference.

To the suggestion made by the *Chicago Medical Examiner*, that the Association be radically changed in its character, and be composed of members who have passed an examination before examiners chosen in the different States, we have the objection that it is impracticable, and, we believe, unwise. Who shall choose the examiners? What standard will be required? Would not the selection of the examiners in the different States cost much wire-pulling and intriguing?

Nothing is harder than to make any examination a test of real worth among practising physicians. One may be a most admirable physician, surgeon, a good specialist, and a successful practitioner, and yet be unable to pass the examination of any of our leading medical colleges. Students who have recently passed, or are just passing their examination for a medical degree, would probably make the best appearance before an examining body, and the majority of practitioners of acknowledged character, skill, and culture, would, in fear, snub the whole thing.

We would modify the proposition of the *Examiner*,

by restricting the right of sending delegates; giving such privilege to medical societies alone. Delegateship is now too common an affair. Officers of colleges are also members of societies. Let them go to the Association as members of their respective societies. As it now stands, the delegateship often goes a begging. Let there be fewer delegates, and let it be an honor to be elected one.

PROGRESS IN QUARANTINE.

Medical science has not progressed more rapidly in any branch than that which includes the study of quarantinable diseases. Advancement in their study is, so to speak, going backward, from the intricate network which ages of superstition and interested policy have woven around the risks of contagion, and substituting instead such judicious precautions as the public safety may demand, and the progressive knowledge of the day may permit.

Venice, in the twelfth century, required a detention of forty days for protection from the dread disease of the Levant; and New York, in the nineteenth century, requires even a longer quarantine than this.

Under the present law all vessels suspected of exposure to quarantinable disease are required to remain at quarantine "for at least thirty days after arrival, and at least twenty days after discharge of cargo," "and perform such further quarantine as the Health Officer requires," unless he shall sooner release them. This requirement, not founded upon good sanitary reasons, and fatal to every business interest, has been a blot upon the statute books, and a standing disgrace to the medical profession.

The present Health Officer insists that in this particular, sanitary science and commercial interest may work in perfect harmony. That while the one demands the speedy discharge of an infected cargo, and the cleansing and purification of the vessel, it at the same time returns the vessel to active commerce in the shortest time.

The temptation of previous officers to avail themselves of this power, and exact, it may be, twenty-five per cent. of the profits of lighterage, towing, and stevedoring,—placed at one hundred per cent. above harbor rates, or the sum of forty thousand dollars as a gross amount,—brought about the bitter dissensions of the past, and culminated in the present course of administration.

The present incumbent, from the beginning of his term, has sought to develop the medical character of the position, and shown uncompromising hostility to the absurd restrictions which, from time immemorial, have been submitted to by his predecessors. The medical profession, for the first time in the history of those now living, have been invited to see the quarantine of New York, great in its interests, magnificent in its proportions, and growing more and more perfect in its facilities to meet the real wants of expanding commerce.

In the Annual Report, now before us, it is evident the sanitary bearings of quarantine are those he professes to develop and make perfect, while the business interests are left where they belong, to the commercial community.

So thorough and complete has this departure been made during the past season, that probably never again will the profession be disgraced by brawls and fights over "lighterage rates" and the "price of coopering;" and Dr. Vanderpoel has earned the thanks of his profession for this, now "*un fait accompli.*"

The new law, which has through Senator Adams been presented to the Legislature, embodies systematically these and other important alterations in the quarantine system. In this law each disease is subject to requirements suited to the special danger which pertains to it. No unnecessary burden is added to commerce, while no relaxation is permitted which might open the door to danger. It simplifies the working detail of quarantine; gives the Health Officer the power which he requires to perform his duty; and, keeping all that was valuable in the old, leaves out that found to be injurious.

THE EDUCATION OF NURSES.

The failures of the medical attendant come largely from bad nursing. Bad nursing is a two-edged sword, which may not only kill the patient, but injure the physician, the nurse alone being exempt. The patient not unfrequently requires a care that the friends cannot be made to comprehend, yet for want of it he often dies. The friends may hint darkly, but the doctor has no opportunity for defence. The latter may call upon a patient once, or in a critical case perhaps twice a day, but what may occur between these visits is too often a source of constant apprehension. To bridge this sometimes fatal gap, he is often compelled to remain by the bedside for hours at a sacrifice rarely appreciated.

If this is the case in the families of the rich, it is still worse in the families of the poor, where not only the skill, but the means of nursing are wanting. Attending physicians of dispensaries know too well how often from this cause their prescriptions are worse than a farce, being made the sole reliance for recovery.

Neither for the rich nor for the poor, in any emergency, is a properly certified skilful nurse to be obtained in this city. We do not say there are no professed or professional nurses, nor that none of these are properly qualified; but that as none have official evidence of it, their competence, in any new case, is a question of experiment.

Not only in private, but in hospital practice also, the advantage of skilful nursing is no less apparent, the demand no less urgent.

The difficulties and evils of the present system in some of our hospitals are too well known to need mention. The duties of a hospital nurse are looked upon as low and obnoxious to the last degree,—and correctly so. To a low person, what employment could be lower or more repulsive? When we know this work is done for hire by those who take such views of it, the manner in which it is done needs neither explanation nor apology. This fact is too apparent, when we consider that much of this nursing, in some of our charitable institutions, is being done by men and women of the lowest type of abandonment, the effect of which, both upon nurse and patient, is obviously little else than one of mutual degradation.

In every hospital, at least, there is a necessity for nurses, who in their department have credentials as high and as authentic as those of the physician in his. This need is manifest and pressing; but at present there is no resource nor remedy.

How may the demand for skilled nurses be supplied? The facts above referred to are not a recent discovery. In other parts of the world the same difficulties have been experienced, and attempts have been in some places made to meet them. The most feasible course of which we know is that which has now for some time been in operation in London, and with such success as to have induced similar efforts in Liverpool and elsewhere.

We are happy to announce, in this connection, the determination of the "Local Visiting Committee of Bellevue Hospital" to establish a similar training school for nurses in New York. Already they have made an appeal to the public for the necessary funds. The project is in thoroughly competent and responsible hands, and has our hearty wishes for its ultimate success.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Our space does not permit us to say much regarding the sixty-seventh anniversary meeting of the State Society, a full report of which we give with this number. We will make a more extended review of the proceedings at another time, and will now only remark the large number of papers of real value which were presented; the unusual attendance, and the interesting nature of the educational, sanitary, ethical, and other questions submitted to the Society.

Few men could have given as much satisfaction as did Professor Agnew, by the manner in which the proceedings were conducted: and the election of Professor E. M. Moore, of Rochester, to be his successor, is a guarantee that the interests of the Society will not suffer from want of as able management during the year to come.

A Substitute for Quinia.—Carbazotate of ammonia is given, with successful results, in France, in place of quinine. It is given in 2 *ctgr.* doses, in the form of a pill.

Reviews and Notices of Books.

New Treatment of Venereal Diseases and of Ulcerative Syphilitic Affections by Iodoform. Translated from the French of Dr. A. A. Izard by Howard F. Damon, M.D. Boston: James Campbell. 1872.

The treatment of venereal diseases and of ulcerative syphilitic affections by iodoform is discussed by Dr. Izard with much earnestness. He advocates for the remedy what cannot be claimed for any other article in the Pharmacopœia, viz.: that it is a specific in the treatment of venereal ulcers, whether local or constitutional. His cases are well recorded and bear the stamp of truth; but the uniform success attributed to iodoform has not been attested by the experience of others. Perhaps, however, the mode of application has not been as thorough as that pursued by Dr. Izard, and hence the unfavorable reports.

The translator has performed his difficult task with remarkable ability; the rendition of the many almost untranslatable idioms into correct, and, we may say, elegant language, giving evidence of his scholarly attainments.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, December 19th, 1872.

Dr. Wm. C. Roberts, Vice-President, in the Chair.

Dr. Stephen Smith read a paper entitled

ERRORS IN THE DIAGNOSIS AND TREATMENT OF SURGICAL ANEURISMS.

The object of the paper was to point out the difficulties which the surgeon encounters in the diagnosis of complicated forms of aneurism, and to establish the limits of responsibility for errors which occur. These errors were divided into *unavoidable*, and *avoidable*: the former being due to the inherent difficulties in each individual case, and the latter resulting from the surgeon's own want of knowledge, or from his unskilfulness. The sources of difficulty in the diagnosis of aneurism were then pointed out, and the diseases which they may simulate were examined in great detail, with illustrative cases.

The affections for which aneurisms are liable to be, and have been, mistaken, by eminent surgeons, are: abscesses, tumors of various kinds, bronchocele, enlarged bursæ, rheumatic enlargement of the joints, malignant diseases, pulsatile tumors of bone, etc.

In each instance the *unavoidable* and *avoidable* errors were carefully discriminated, with a large number of examples illustrating each variety.

Dr. R. J. O'Sullivan, in responding to the request of the Vice-President, said that he would contribute his mite to the discussion of the subject. He confined his remarks to the relation of three cases which, he thought, would corroborate the views of the author of the paper as to the diagnostic difficulties referred to.

The *first* case was one that was observed by him whilst visiting one of the hospitals of this city, as he was in the habit of doing during the first years of his practice. The visiting physician called his attention to a patient who had just been admitted to the medical wards. The patient had a small tumor in the popliteal

space, which, though in a suspicious place, presented few of the diagnostic symptoms of aneurism. On balancing a pencil on the tumor, he detected pulsation distinctly; from these and other circumstances he inclined to the belief that it was an aneurism, which opinion was concurred in by the attending physician, and some other medical gentlemen who were present. The patient was transferred to the surgical division. A few days afterwards, in passing into the ward, he noticed the patient minus his leg, and on further inquiry he learned that a consultation had been held and it was decided that the tumor was an abscess. It was accordingly opened, and the fact demonstrated that it was an aneurism. Amputation immediately followed.

The *second* case that he mentioned was one calculated to demonstrate the difficulties in the differential diagnosis between aneurism and abscess. A few years ago, an Englishman came to his clinic at the Eastern Dispensary with a pulsating tumor situated above the sternum, which seemed more like an aneurism than anything else. It was so decided by several prominent medical men of the city. After attending for some time he suddenly disappeared, and he did not again see him for several months. The patient then asked if he remembered him, saying that he was the patient who had the "Haneurism of the Heart," and produced a paper—covering several pages of foolscap—giving the history of his case, and detailing the diagnosis and remarks of the medical gentlemen who had examined him. In brief, he was admitted to one of the city hospitals, where the tumor was diagnosticated an aneurism; and his family were informed that they might soon expect his death, as he would certainly die when the tumor ruptured. When that took place the existence of an abscess was made evident, and the patient lived to tell his own story.

The *third* and last case mentioned was that of a Chinaman with a large pulsating abdominal tumor, which had all the appearances of an aneurism. Two or three distinguished surgeons were called; one failed to make a diagnosis of any kind; another said that the tumor was attached to the left lobe of the liver; finally, the late Dr. Valentine Mott saw him and examined him very carefully, and pronounced the tumor to be an aneurism, adding that it was not as well defined as some that he had seen. On the death of the patient the autopsy revealed a carcinomatous tumor lying on the abdominal aorta.

The speaker concluded his remarks by saying that this region was as yet but an imperfectly explored territory, and hoped that some American genius, perhaps a member of the Academy, would yet discover some instrument which would enlighten the profession, and do for this region what auscultation has done in treating disease on the other side of the diaphragm.

Dr. A. L. Loomis alluded to the use of the thermometer in diagnosticating tumors—which was not mentioned by Dr. Smith. In no case of aneurism which he had tested by the thermometer was there a temperature of over 100°. He believed that this instrument was one of the most valuable means of diagnosis.

Dr. J. C. Peters supposed that Dr. Smith would have included all varieties of aneurism with his surgical cases, and recalled some of the cases which were recorded in the Proceedings of the New York Pathological Society. There were three cases of aneurism of the basilar artery; nine of the coronary artery; eleven of the walls of the heart; and thirty-three cases situated just above the aortic valves, and perforating into the pericardium, causing instant death. One of the earliest cases was described by Dr. Markoe in 1842. In three or four cases there was rupture of the internal coat. Some were as high up as the arch of the aorta, dissecting down to the pericardium, into which they finallyruptured; then death was slow instead of instantaneous.

Dr. J. R. Van Kleek said that he had a patient with rupture of the aorta into the pericardium, who lived twenty-two hours. He also spoke of a case of embolism of the pulmonary artery, in which the patient died in ten minutes. In response to Dr. Loomis, he said no examination of the brain was made.

The Academy then adjourned.

Twenty-Fifth Anniversary Meeting, Dec. 30, '72.

Dr. Edmund R. Peaslee, President, in the Chair.

Dr. Edward S. Dunster delivered the annual discourse, of which we give an abstract, regretting the want of space for its publication in full.

After alluding in the introductory to the years which have rounded a cardinal division of the first century of the life of the Academy,—years which have been characterized, on the one hand, by marvellous advances in the arts and sciences, and on the other by a freedom of thought so active, so bold, so iconoclastic, as to have brought constantly upon this day and generation the charges of infidelity, scepticism, and even graver forms of unbelief,—the speaker said that this active, bold, iconoclastic thought, much of it undoubtedly speculative, but more of it based on a rigid and logical induction of observed phenomena, has pervaded almost every department of knowledge; it has changed entirely the aspect of many of the physical and organic sciences; has shaken systems and theories which were considered immovable; has unhinged beliefs which were accepted as conclusive, and caused a distrust of others that were assumed to be equally secure; has wrought the direst confusion among the theological and metaphysical conceptions of the order and evolution of the universe, and the estimate of man's place in nature; has reached even to religious beliefs, and already has shorn them of much of their harshness, their terrors, their uncharitable intolerance; in short, has brought about so many antagonistic opinions, and has unloosed so much distrust and suspicion regarding everything that finite intelligence can lay hold of, that we may, with propriety, ask ourselves whether the charges to which allusion has been made are not well founded.

Is the medicine of to-day based upon any solid foundation? Is its future assured, or is it now, and must it always be, a shallow empiricism, dependent for its form upon caprice and fashion, and relying for its support upon credulity and ignorance? It seemed to him that a little reflection would show that the medicine of to-day is a logical outcome from its past history, its failures and successes, its incongruous mixture of truth and error, and that, measured by the same standard, its future progress, though indeterminate as to rate, is assured beyond all doubt,—in other words, there is a logic in medicine which governs its evolution and measures its progress.

By the term "logic" is here understood, not the *pure* logic of the schools, which is concerned only with the laws of the form of thought, but *applied* logic, which has reference to the matter, or facts, or truths of the objects and phenomena to which thought is directed. In this sense, then, the logic of medicine acquaints us with the processes by which the mind arrives at that appreciation of the facts and phenomena with which the physician has to deal, which constitutes empirical or experimental truth. Its office, therefore, is not to disclose truth, or fact, or doctrine in medicine, but to

acquaint us with the real value of the ways and means by which such disclosures are attained; to enable us to judge whether our investigation has been conducted by proper methods; to warn us of error or fallacy, and to furnish us with data whereby to test the correctness of our conclusions. It is a logic which is equally applicable to all the so-called experimental sciences, and which, in many of them, by reason of the greater simplicity of the conditions under which phenomena are observed, has resulted in such a comprehensive and precise acquaintance with the laws which govern those phenomena.

The inductive method, first distinctly formulated by Bacon, and one of the means of arriving at the truth in the physical sciences, was dismissed by the speaker with a full acknowledgment of the valuable services it has rendered.

Inasmuch as the knowledge gained by observation and experiment is inadequate to the final result, he remarked that we make another advance in the step of comparison. Logic brings in as auxiliaries here classifications, analogies, and statistics, and shows their true value and uses, the extent to which they may be carried, and the validity of the deductions that may be made from them. It further guards against inaccuracy by declaring that the facts compared must be of the same kind, as nearly identical as may be possible in the nature of things; by showing that they must be brought together in sufficient numbers to enable us to correct errors of individual observation, to determine what has uniformly occurred either as antecedent or resultant, to distinguish between constant and accidental sequences and coincidences, and to pick out by exclusion the efficient cause or causes, where, as is continually the case in so complex a structure as the human body, many are acting at the same time.

Logic forbids all ambiguity in the terminology, definitions, and descriptions employed in medicine, and demands that such technical language must represent actualities, and must not include any misstatement of fact; must be devoid of surmise, and must not be a cover for our own ignorance. The medical nomenclature, even of to-day, is in open disregard of this rule of logic, and it is no easy matter to correct it. It has come down as a legacy from former generations, when the terms were devised in accordance with the best information then extant; and although subsequent knowledge has shown the incorrectness of very many of such terms, they have become so incorporated into our modes of speech that we cannot now escape them. The mischief accruing, therefore, is almost incalculable, as it is well-nigh impossible to secure anything like precision of thought or an accurate habit of expression by the employment of a terminology that is notoriously ambiguous, incorrect, and unsatisfactory. Centuries have been required in the formation of our technical language, and it will require centuries more to remove the disabilities that have thus been imposed upon us. But logic shows us the way out of the difficulty, and imperiously demands that we avoid it in any additions that may hereafter be made in our medical nomenclature.

With the dawn of Protestantism, in the beginning of the 16th century, there was ushered in a spirit of free inquiry which soon brought about a more healthy state of opinion, and which, coupled with the diffusion of knowledge, has at last made it well-nigh impossible for men to stand spell-bound at the assertions of authority. And so to-day, in a far more logical and philosophical spirit, when a Cohnheim, following up the track of Waller's original observations, asserts the passage of the white corpuscles bodily through the walls of the minute blood-vessels, we neither affirm nor deny the apparent paradox, but, with the true spirit of the logic of medicine, hundreds of microscopes are at once brought to bear on inflamed tissue, to test the truth or falsity of the assertion; while the theory which is based on the fact is held in abeyance until further experiment and comparison shall have fulfilled all the requirements of logic before accepting the theory as established truth. And so, again, when Liebreich, by a process of purely logical deduction, suggests that an article hitherto known only as a chemical curiosity may become a serviceable medicinal agent, and boldly puts it to the test of administration, we applaud his scientific spirit of inquiry; but still reserving to ourselves the logical right of search, thousands of human stomachs, the world over, are at once impressed into service, and straightway there is added to the materia medica a remedy of great potency and of unquestioned value.

Passing by the absurd and crude notions which attributed disease to supernatural causes, the anger of the gods, the malign influence of the stars, etc., we can trace in almost every prominent theory the idea that disease is something added to the body, and which is accordingly to be removed. Thus, at one time it is an excess in some of the humors of the body; at another, morbid or chemical or mechanical forces overcoming or acting in opposition to the healthy forces of the body. Again, it is an effort of nature to expel some noxious material, and now it is a morbid deposit, which by its presence sets up some disturbance of the system. Happily these ontological conceptions of the nature of disease are passing away, and the whole tendency of modern medicine is to take essentially the opposite view,—that disease, under all its manifestations, is only a perverted healthy process; something less as it were than life, and out of this comes the prevailing system of therapeutics known as the restorative method. It implies, first, a scientific recognition and examination of healthy phenomena (physiology); and next, an equally rigid inquiry into unhealthy phenomena (pathology); and finally, in determining the therapeutical indications, it does away with much of that vain search after specifics which has so hindered the progress of medicine.

This diminishing belief in specifics is more apparent as we come down from the limited professional knowledge of the past to the greater of our own time, and everywhere it may be said to be in proportion to the ignorance of the people; and accordingly, with the best informed physicians of to-day, the question is not what drugs shall be prescribed, but shall there be any treatment beyond rest and an appropriate regimen; and if his knowledge tells him that these last are sufficient for the case in hand, the physician courageously withholds all medication; and now, when some ill-informed person flings back that ugly word scepticism to indicate his estimate of what, with a show of learning, he will probably style, in the well-worn phrase of Asclepiades, "a meditation upon death," the reply is ready,—that a knowledge which can dictate such a management of a case has in it not a single element of doubt, and is, therefore, as far as possible removed from scepticism. It is vastly more positive and more serviceable than mere faith in the efficacy of drugs without knowledge, "which, in medicine," says Sir William Jenner, "is the worst form of scepticism, inasmuch as it is doubt of truth and belief in error—doubt which may prevent the saving of life, and belief which, embodied in practice, may kill."

By reason of increased knowledge we can more cor-

rectly than heretofore theorize regarding the nature and origin of many diseases, and this may be done with propriety; for logic, as has already been seen, does not exclude theory. In support of this position, let us briefly refer to some of the more noticeable advances of recent years; and in so doing it will be seen that the assertion which has been so frequently, yet carelessly made, that, while the science of medicine has been steadily progressing, the art has remained almost stationary, is not founded in truth. On the contrary, it seemed to him that the tendency and efforts of the present day are rather to give to the art more and more the impress of science. The two are not and cannot be synchronous in their evolution, as has already been shown. If, then, we pass by anatomy, the present state of which borders closely on perfection, and if we also omit physiology and pathology, which in reality are but the two extremes of the same branch of science, and in which the most wonderful advances have been, and still are, going on, and confine our illustrations to clinical medicine and surgery, we shall find the special improvement so abundant as almost to be confusing in the numeration.

And first, look at the constantly increasing certainty in diagnosis. The microscope, the test-tube, the thermometer, and various other appliances of science, have given us an insight into disease that a century since would have been deemed simply chimerical. The distinction has been closely drawn between diseases that were formerly considered identical; and new diseases, by the same process, have been added to our nosology.

Auscultation and percussion; the use of the ophthalmoscope and microscope, and many other improvements, are the direct results of the introduction of the methods of the physical sciences into the province of medicine, and there is some danger, perhaps, in the tendency which of late years has been evident, to rely so largely upon an exclusively physical diagnosis. Equally important advances, however, have been made by a comparison of the results obtained in pathological investigation with the objective signs of disease. In this way the lesions of the brain and spinal cord and all the internal organs; the mechanical origin of certain diseased states, such as follow obstructions in the circulation of the blood, as in thrombosis and embolism; the relations of local affections to constitutional states, with the important bearing thereof upon prognosis,—all this and much more valuable information is now permissible even from the clinical history alone of a patient.

Outside of diagnosis, the evidences of advance are not less numerous, and are of equal importance. Ovariotomy, at first decried and opposed in the most virulent manner, has been recognized as a legitimate operation in surgery, and yearly it now saves hundreds of lives that, but for this mode of interference, must have soon ended. Anæsthesia has put an end to the torture under the knife of the surgeon, has become a most powerful agent in the management of convulsive and painful nervous disorders, and has abolished the sufferings of parturition, although this application of its beneficent power was at first deemed impious and Heaven-defying. Hypodermic medication has given a promptness and efficacy to the action of remedies that could not be secured in any other way. The conservative influences of surgery are seen in the resections of joints and the saving of limbs that but a few years since were inevitably sacrificed. In the single department of urethral and cystic diseases, the surgeon of to-day has at his command means of saving life and mitigating suffering that alone are enough to place the art of to-day high above that of any preceding age. In medicine, the researches of Fox, and Sanderson, and Villemin have thrown a flood of light upon the origin of tubercle, and have largely modified our views of the nature of phthisis. The relations of syphilis to degenerative changes and early decay are becoming well understood. A clear line of separation has been drawn between diseases proper and the processes of degeneration that are peculiar to adult and old age, and the often conservative nature of such degenerations has been distinctly proven. The origin of typhoid fever has been traced to foul sewage and the impregnation of drinking water with fecal matter. The connection between septicæmia and impure air has been so universally demonstrated that it has become a serious question whether, in many instances, our hospitals and asylums are anything more than agents of destruction. The bearing of soil-moisture upon the prevalence of consumption has been made an especial study in our own land, and a steady diminution in the number of cases has followed the removal of the cause. The modes of the communication of contagious diseases are ascertained, and the prevention of their spread is entirely within control, provided only that sufficient power be delegated by the state authorities. Oesterlen was right when he said that, "in point of actual knowledge even a Celsus or a Hippocrates, a Boerhaave or a Sydenham, would be a smatterer in comparison with any practical physician or physiologist of the present day;" and let us not forget that all this is a logical outcome from the adoption of methods which have done away with many sources of error that were prevalent in former times.

Prof. Dunster then spoke of the illogical method of our medical education, and as follows concerning the future of medicine: It needs no skill in prophecy to assure us, that, so long as she clings to the methods which logic has established, her progress must be continuous; for although much has already been accomplished, especially since she has entered upon the era of positive knowledge, or, in other words, has adopted scientific and logical methods in her work, there still remains an unexplored field which, properly worked, must yield results that we can now hardly dare to conceive of. From past experience to new circumstances, it is universally conceded we can only argue in accordance with an observed uniformity in the order of events. Unless such uniformity existed we could infer nothing. There need be no misgivings as to the future; nor, on the other hand, need we reproach ourselves that the advance is not more rapid.

It is an easy matter to surmise the direction in which the greatest advances will be made in the future, though the mind is dazzled in attempting to reach the degree of advance. As to the first, the greatest deficiencies are, curiously enough, in the two departments of clinical medicine which are respectively the beginning and the end of the physician's study and work; viz., ætiology and therapeutics. In the intermediate departments of pathology, diagnosis, and prognosis, our knowledge, though by no means perfect, is more advanced than in either of the other two; and it is a striking illustration of the principles attempted to be shown in this paper, that our information is most exact in that section where the demands of logic have been most nearly conformed to, or, to state it differently, where the laws of applied science have been made to bear upon the investigation of disease. In the first two of these divisions of clinical medicine the principal means of further advance will be found in organic chemistry and the physical sciences. In prognosis, reliance must be had on a more

complete study of the natural history of disease, etc. In therapeutics—the final and supreme stage of medicine—as Sir Thomas Watson styles it, there is the most work to be done; our only knowledge now is that of experience. We are almost in entire ignorance both of the mode of the operation of medicines and the intimate nature of the changes they produce in the system; and this cannot be otherwise so long as ætiology remains in its present lamentably deficient condition. To isolate morbific principles, and to ascertain the exact nature of all disease-producing agents, and to learn accurately the initial changes wrought by them, are clearly the preparatory steps to an acquaintance with the laws of the cure, not the recovery, of disease. But even this knowledge is not impossible; there can be no doubt that sooner or later the laws underlying the therapeutic actions of remedies will be reached; that there are such laws it seems to me is indisputable; for law, which is not a self-acting agent, but only the expression of God's will in the workings of the universe, is present and acting everywhere and under all circumstances; and as in the past and the present, so it will be in the future that the impediments in searching out these laws will be found to lie less in the intrinsic difficulties of our subject than in the erroneous and illogical methods of conducting investigation into them. The future, then, is full of promise; and we may well content ourselves with the reflection that as centuries upon centuries have been spent in bringing about our present advanced position, so hereafter each successive decade will give a steadily increasing development. I plead for the entire abandonment of all faulty methods of investigation and reasoning, and for a still firmer alliance with those which in other quarters have produced such solid and brilliant acquisitions; for a diminishing reliance upon the "blind gropings of empiricism," and a still closer affiliation with the whole temper of modern science; for the exclusion of all fallacies, and the adoption of every safeguard which can indicate a wrong direction in our labors; for the final displacement of self in the interpretation of the phenomena of life, and the concentration of all our powers in searching out and verifying the laws which govern the relation and succession of those phenomena; in a word, I plead for the incorporation into all our studies and all our work of the logic of medicine.

The Academy then adjourned.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, November 27, 1872.

DR. A. L. LOOMIS, PRESIDENT, in the Chair.

(Continued from Page 67.)

INTERESTING CASE OF HEART AND BRAIN DISEASE.

DR. LOOMIS exhibited specimens of the heart, kidney, and a portion of the brain taken from a German tailor who was admitted into Bellevue Hospital the 18th of November. This man said that he had always been well up to five months ago, but that four or five years ago he had had intermittent fever, from which, however, he readily recovered. Five months ago, after exposure to cold, he began to cough and to spit blood. He also noticed that he passed more than the usual quantity of urine; that he was rapidly growing weak; and that he suffered somewhat from dyspnœa and shortness of breath on exertion. About four weeks previous to admission, he noticed that his feet began to swell, and that at the same time the urine became scanty and high-colored. There was also some pain in the back; the dyspnœa was more urgent than before; and his face became swollen in the morning. At the time of admission he was extremely anæmic. There was dyspnœa only on exertion, and there was then neither cough nor expectoration. He had no œdema of the feet or of the face. His abdomen was swollen and tympanitic. There were evidences of a slightly enlarged liver; and the upper portion of his abdomen was more prominent than the lower portion, especially in the epigastric region. His pulse was feeble but not accelerated. He complained only of extreme weakness and dyspnœa on the slightest exertion.

On auscultation, the heart was found to beat in the sixth intercostal space, an inch to the left of its normal site. The impulse was indistinct and was diffused over an abnormal area, there being a somewhat indistinct heaving sensation over the whole precordial space. There was a murmur before the first sound, heard with greatest intensity at the apex. There was another murmur with the first sound, very loud, carried around to the left, and heard distinctly at the lower end of the scapula; also, a murmur heard at the base, more blowing in character, conveyed upwards, and heard in the carotids. The diagnosis of mitral obstruction and regurgitation was made. The question of aortic obstruction was raised, but not satisfactorily answered. There was no murmur with the second sound.

The urine contained albumen and granular casts.

He finally became more stupid than patients generally are in his condition; his mind seemed to be sluggish. There was no aphasia present; at least such a condition was not noticed by any who saw him.

On making the autopsy, the heart was found increased in size in all directions. The left ventricle was a little less than its normal thickness. Upon one portion of the aortic valve there were vegetations a quarter of an inch in length. These valves were found slightly deficient. There were vegetations upon the mitral valves of considerable size and having a calcareous feel; the orifice itself being somewhat diminished. These vegetations seemed to be upon the ventricular surface for the most part, and apparently extended into the cavity of the ventricle. The coronary artery was found obstructed by an embolus. The right side of the heart was dilated, but the walls were not thickened. Dr. L. remarked that there ought to have been an aortic regurgitant murmur. If present, it must have occurred after the closure of the aortic valves, and might have been the pre-systolic murmur which he supposed to indicate the mitral stenosis.

Upon the surface of the kidney there was a distinct depression which corresponded to an obstruction in a branch of the renal artery, which was evidently of a calcareous origin, and which had given rise to an infarction beyond.

In the brain corresponding to the Island of Reil, was an infarction which occupied the whole of that portion of the brain, and should have given rise, according to present theories, to aphasia.

ANEURISM PRESSING ON RECURRENT LARYNGEAL—LARYNGOTOMY AND NO RELIEF FROM SPASM.

DR. LOOMIS presented a second specimen which was of interest as regarded a diagnosis, the latter not having been made during life. It was removed from a woman, aged forty-five, who was admitted into Bellevue Hospital November 23d, with the statement that ten years ago she had an attack of acute articular

rheumatism; that she was under treatment for the same in the wards of Bellevue for three months; that two years after she had an attack of pneumonia, from which she recovered. With these exceptions, she had been perfectly well up to three weeks before admission, when she noticed that she was short of breath on going up-stairs. She had also some cough and expectoration, with febrile excitement and pain in the chest. On exposure to cold the cough would become quite violent, and was always attended with expectoration. Two weeks before admission she fell suddenly to the floor in a fit of dyspnœa. Her difficulty of breathing was so great that her friends thought that she was dying. She recovered in the course of two hours, and was only left with a cough which was a little more severe than before, and had a stridulous character. Four days after that another paroxysm, of the same character, came on, which lasted an hour and a half. While preparing to go to the hospital, she was seized with another attack while in the carriage, and she had not recovered from it when admitted. Her lips were blue; she was intensely cyanosed; and there was a peculiar crowing sound on inspiration. A drop of nitrite of amyl was administered in chloroform by inhalation, but it did not seem to have any special effect. The paroxysm finally passed off of itself. On her recovery, she stated that she had no pain.

On physical examination, no evidences of disease of the lungs were found. Knowing that this character of inspiration generally accompanied aneurism, with pressure upon the laryngeal nerve, a careful examination was made accordingly, but with a totally negative result.

The patient went on comfortably until the morning of the 24th, when the House Physician, Dr. Bangs, made a laryngoscopic examination of the patient. When the mirror was passed back into the throat, a paroxysm of dyspnœa came on more violent than either of the others. So urgent did her symptoms become that the doctor prepared himself for laryngotomy. Dr. Bangs, by subsequent examination, ascertained that the vocal cords were normal as to appearance. At his next visit, Dr. Loomis passed his finger into the posterior portion of the throat, down to the epiglottis. He touched that organ, but before he could remove his finger a very severe paroxysm came on. This one lasted an hour and a half. The morning of the following day (25th) she was seized with another, which lasted two hours. She was then in a comatose condition, or rather unconscious; was almost pulseless; her extremities were getting cold; her eyes did not respond very well to light; her lips were blue, and she seemed to be dying. Dr. Bangs performed laryngotomy, but the operation, strange to say, did not give her the expected relief. Artificial respiration was kept up two or three hours before the blueness passed off, and during this time she was unconscious. She finally began to breathe easily, but only for three hours, when another attack came on. After clearing the tube and irritating the larynx, the paroxysm gradually passed off, but she breathed only imperfectly until the following morning, when she died.

On making a post-mortem examination, the heart was found larger than normal. Passing up from the base of the heart, an aneurism was found given off at the junction of the transverse and descending portion of the aorta, and pressing downwards upon the recurrent laryngeal nerve. It also pressed upon the left bronchus, not sufficiently, however, to interfere with the passage of air through it. At the point of pressure, however, there were some evidences of recent inflammation. The case was made plain enough by the autopsy, except the fact that the introduction of a tube below the vocal cords did not entirely arrest or prevent a paroxysm. A question naturally arose in connection with this case as to the propriety of an operation.

Dr. Janeway remarked that his experience did not justify such a procedure. He had met with three cases in which an operation had been performed: the first died a week after from pneumonia, and the second lived but a day.

Dr. Post thought that the operation was justifiable if life was only prolonged a few hours, especially as the operation was not attended with any injurious consequences.

Dr. Loomis could not explain why the introduction of a tube in the larynx did not relieve the dyspnœa, allowing that said dyspnœa was produced by closure of the vocal cords by pressure upon the inferior laryngeal.

Dr. Janeway remarked that during one of these paroxysms he asked the patient her name, when she gave it to him, thus showing that the muscles of phonation were not involved. If the paroxysm were due to pressure upon the inferior laryngeal, he did not see why the voice-sounds were made. In that view he could not understand why one function of an affected nerve remained perfect while the other was temporarily extinct.

Dr. Sands thought that inasmuch as the introduction of the tube did not relieve the dyspnœa, it might depend upon pressure on the bronchus, the aneurism being large enough to make a tangible impression upon that tube.

Dr. Loomis stated that whenever the patient became excited by the presence of a stranger or any other cause, a paroxysm would occur. This fact gave plausibility to the explanation offered by Dr. Bangs, to the effect that at such times the heart was excited, and distended the tumor sufficiently to hinder the entrance of air into the lungs.

Dr. Castle, in this connection, said that the mode by which dyspnœa is produced is not fully understood, and referred to some remarks made by Dr. Brown-Séquard before the Journal Association. That gentleman, speaking of artificial respiration through a tube in the trachea, remarked that the moment a current of carbonic acid gas was passed in a reverse direction over the vocal cords, violent respiratory efforts were made. Dr. Castle had frequently noticed, in the performance of similar physiological experiments, that if he compressed the nares of a dog, even when air was being forced freely through the tracheal tube and the animal was making no respiratory movements, respiratory efforts would at once commence.

Dr. Jacobi remarked, that so long as there was difficulty only in inspiration, the voice did not necessarily become extinct, a circumstance often seen in croup.

Dr. Loomis stated that the laryngoscope showed no paralysis of the vocal cords.

Dr. Janeway thought that the pressure upon the bronchus was very inconsiderable compared with some cases which he had seen, and in which no paroxysmal dyspnœa was present. In one instance to which he referred, one bronchus was for a time completely blocked up by a clot from a ruptured aneurism.

Dr. Putnam did not think that the pressure should be excessive to produce such paroxysms.

Dr. Markoe referred to the interlacement of the fibres of the pneumogastric with some of the descending branches from the sympathetic, which encircles and lies pretty close to the bronchial tubes. If that plexus were subjected to pressure by an aneurismal tumor, a spasmodic, or rather perverted action might be re-

flected to all those portions of the pulmonary apparatus supplied. This might explain the persistence of the paroxysms despite the free entrance of air through the tube in the larynx.

The Society then went into executive session.

Correspondence.

MEDICAL EDUCATION AND HARVARD UNIVERSITY.

DEAR SIR—In an article published in the MEDICAL RECORD a short time since, many good suggestions were made in regard to Medical Education, and the hope was expressed that they would attract the "attention of those concerned with the future education of our medical men," so that they might "judge how far such changes are feasible."

Though "important changes that have taken place in one of our sister colleges" are alluded to, they are apparently not recognized as of special interest in connection with the points so strongly insisted upon in the article.

Fearing that the Prospectus of the Medical School of Harvard University may not show as clearly as it should the character of the instruction given, I hope you will pardon me for saying that a year's experience in the kind of teaching you advocate, has proved it to be not only feasible but a complete success.

In addition to the didactic lectures usually given in Anatomy, Dissection is required, and the student receives from a special teacher, in a laboratory arranged for the purpose, personal instruction in Histology, both normal and pathological. In this exercise each student uses his microscope and is taught all the details of its management, and of the preparation of specimens. In Physiology also the more advanced students have opportunities to work in the Physiological Laboratory.

In Chemistry the greater part of the time is spent in the laboratory.

In Auscultation and Percussion and in Laryngoscopy a separate instructor gives the most thorough drill upon actual cases.

In Clinical Medicine the instruction is strictly practical, cases being supplied which the students must make out without aid, and report before the class, and this is done during nine months of the year. In the same way the student is drilled in operative surgery and all surgical manipulations. If he leave the school without, as you suggest, any "practical acquaintance with Ophthalmology and Otology," it must be his own fault, as he has abundant opportunities to learn both in the most practical manner.

All the above, usually treated as accessories to a proper medical education, are here a part of the regular systematic course, as much as the lectures or recitations.

You will therefore see how inapplicable to us is the statement "that even in our largest cities, where cultivation and refinement rank highest, and where the demands on our profession are as exacting as in any part of the civilized world," the medical colleges do not "furnish us with thorough theoretical and practical instruction in all branches of medicine practised among the profession at large."

The true way to meet the objection "that the student's time is fully occupied with courses recommended," is to so distribute and arrange his labors as to avoid the inevitable *waste* of time involved in the prevailing American system. Yours very truly,

C. ELLIS,
Medical Department of Harvard University.

BOSTON, *January*, 1873.

TABLE OF DEATHS BY PHTHISIS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR.—As supplementary to the valuable paper by Dr. Flint, in your last issue, I beg to present a Table of Deaths by Phthisis in this city, for three years, so arranged as to exhibit the relative mortality of various professions. The years 1869, 1870, and 1871 are selected on account of their extending over a period equally preceding and subsequent to the time of the last census, and therefore by compensation affording a fair average. The list embraces only those callings which correspond in both the census returns and the statistics of this bureau for the years specified.

Respectfully,

CHAS. P. RUSSEL, M. D.

Bureau of Records of Vital Statistics,
New York, February 7th, 1873.

TABLE showing the influence of various occupations upon Phthisis Pulmonalis, in New York city.

OCCUPATION.	Number of Persons engaged in (Census of 1870.)	Average Number of deaths annually by Consumption, in 1869, 1870, 1871.	Deaths by Consumption in each 1,000 persons.
Laborers (including quarrymen, agricultural laborers and porters)	28,700	329.3	11.5
Coopers	1,606	13.6	8.5
Machinists (including blacksmiths and metal workers)	11,178	92.3	8.2
Lawyers	1,283	10.0	7.8
Seamen and watermen (including sailors and steamboatmen)	4,463	34.6	7.7
Boot and shoemakers	6,960	54.0	7.7
Barbers (including hairdressers)	2,549	18.3	7.2
Carmen (including coachmen and teamsters)	9,813	69.3	7.1
Printers	5,134	36.0	7.0
Painters (including varnishers)	5,824	40.0	6.9
Masons and stonecutters	6,586	44.6	6.8
Carpenters (including cabinetmakers, upholsterers and joiners)	15,498	103.0	6.6
Dressmakers (including milliners, mantua-makers, tailoresses and seamstresses)	18,614	120.0	6.4
Teachers—female	2,173	13.0	6.0
Tailors	9,696	55.6	5.7
Bakers	3,855	21.3	5.5
Bookbinders	2,256	12.0	5.3
Cigar makers (including tobacco workers)	5,550	29.0	5.2
Domestic servants	49,440	253.0	5.1
Butchers	4,870	22.3	4.6
Clerks (including salesmen and accountants in stores, banking, brokerage, insurance and manufacturing establishments, and civil employees of government)	37,432	163.0	4.6
Hatters (including hat and cap makers)	1,744	6.6	3.8
Physicians and surgeons	1,741	6.6	3.8
Peddlers (including hucksters and commercial travellers)	4,744	18.6	3.8
Merchants (including traders and dealers)	28,872	75.3	3.1
Stablemen (including livery stable keepers and hostlers)	1,278	4.0	3.1
Teachers—male	1,298	3.0	2.2

ENORMOUS FATTY DEGENERATION OF LIVER, Etc.

To the Editor of the Medical Record.

Sir—At a meeting of the Pathological Society, reported in a recent number of your Journal, I had the honor to submit a case of malignant icterus, with fatty infiltration and degeneration of the liver, but also enormous hypertrophy instead of the acute atrophy usually found in such cases. I have since found a similar case related by Wunderlich in the *Archiv für Heilkunde*, 1863, and quoted in the *Archives Générales* for the same year. In this case, death occurred after symptoms similar to those I have described, and at the autopsy was found an enormous fatty degeneration of the liver and kidneys, with sanguinolent effusions in the subserous cellular tissue.

It would appear therefore that the liver may become shrunken and softened, with its cells reduced to a fatty granular detritus; or, enormously enlarged, with only partial destruction of its elements, while the remainder appear distended and *infiltrated* with fatty globules. I am, sir, yours truly,

Mary C. Putnam, M.D.

328 E. 15th St.

New Instruments.

A NEW FORCEPS.

By H. LÖWENTHAL, M.D.

Some of our most distinguished writers and teachers on obstetrical subjects have recommended that the study of the forceps be more cultivated, because they are the means of saving in extraordinary cases one or two human lives. The consequence of these recommendations has been the invention of a host of new forceps, all for the purpose of facilitating the application and of increasing the effect of this valuable instrument.

Some made a new lock, others changed the length of the blades, the size of the shafts, the move of the handles; others, again, thought small fenestræ in the blades would be more efficient, or broad blades would hold the fœtal head more securely than narrow ones; others finally changed the curve of the blades, made two curves, or one curve, or none at all, and so on. But to show to the profession that those hints were not lost on me, I tried to find out how it were possible to apply a forceps without subjecting the mother (and often the operator) to the difficulty of applying the second or right blade and locking the forceps; in other words, I tried to find a forceps whose blades could be introduced at once, and by which the head of the child could be caught by rotating one blade around and away from the other; and I give you in the accompanying cut an idea of the instrument I had made. I have tried it on the phantom, and finding it perfectly successful, I offer it to the profession, knowing full well that there is a great deal of room for improvement, as regards the length and width of the blades, and the curves of the same.

I shall now endeavor to show in what way my instrument is superior to all the others.

I do not think that there is any necessity for speaking of the effect of the obstetrical forceps in general, since almost every medical journal of the last year or two contains essays on the same subject, written by more able and more experienced authors, but I shall only mention that just these essays brought me to the idea of having my forceps constructed.

The forceps should act as tractor, as compressor, and as lever, and I think the arrangement of the lock of my forceps meets these claims best of all.

The lock, being solid and stationary, is more apt than

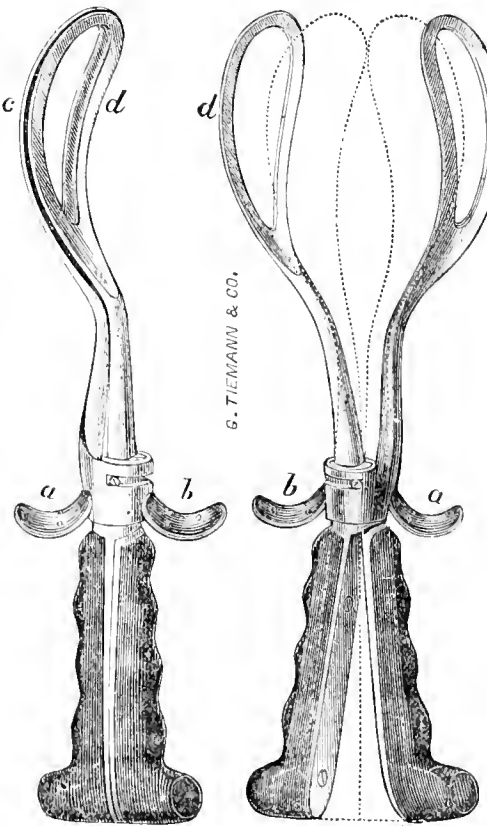

Fig 1. Fig 2.

any other to procure for the operator a steady traction; the blades, working around a joint, will give a higher degree of compression than any other (without being too much in that direction, because if the head were too large, the rotation of the blades could not be accomplished), and the whole instrument being straight, and the handles, working as it were like one piece, will give a greater amount of leverage than any instrument the handles of which have to be compressed by the hands of the operator in order to steady the instrument.

So much in regard to the general application of the forceps; but there are a few new points to be remarked in my instrument, which are well worth being mentioned. First of all, it does away with the introduction of the second blade. Every medical man who has been called upon to apply the forceps will agree with me that the greater difficulty is always in the application of the second blade and the locking of the instrument. After you get the first blade in position, you will have to intrust its handle to some assistant (usually an inexperienced woman) to hold and steady it, and at the same time keep it out of your reach, not to hinder you in applying the other blade. While you are busy in doing so, this assistant will move or let go the handle, and thereby necessitate adjustment of it again, before you can proceed with your work. Finally you have

both blades in position, and try to lock them, but you find some difficulty in doing so: you will have to move either the first or the second blade, and sometimes not with inconsiderable force, thereby risking the making of abrasions on some part of the child's head. All these difficulties are done away with: you introduce your instrument as you do the first blade of any of the other instruments. There is usually very little resistance: then seize hold of both handles with one hand, and rotate the instrument either to the right or to the left, either around the anterior or the posterior half of the pelvis, and as soon as the two blades come opposite to each other, with a click the lock will close, and you can commence traction, or use leverage, at your discretion, as the case might be, without fear lest the instrument might open, or the blades might move, and without using any force to compress the handles, as with other instruments. This instrument, as I present it now, could be made of any length, but I intend to use it as a straight forceps, and shall always follow the old rule of putting the mother across the bed on her back, bringing the nates close to the edge, thereby giving the most space to the operator.

In closing this explanation I do not need to give any further description of the forceps, as the construction of the blades, or handles, or shafts, has nothing new, nor is it necessary to give further directions for the use of the instrument, since it is so simple that every practitioner who has ever handled a pair of forceps before, will at once understand the workings of this new one: the only point to be noticed, if you want to rotate the outer blade around the posterior half of the pelvis, is to steady the instrument on both sides at the horns of the handles with one hand, and rotate the instrument by grasping the lower end of the handles with the other; on the other hand, if you want to rotate the inner blade around the anterior half of the pelvis (behind the os pubis), you steady only the one handle and rotate with the lower end of the other, or, as the cut shows, in the first case, steady the instrument, by putting one hand around *a*, *b*, and rotate blade *c* backward; in the second case, steady only handle *b*, and rotate blade *d* forward.

91 Second street.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from January 19, 1873, to *February* 4, 1873.

McMillin, Thos., Assistant Surgeon.—To accompany batteries of 4th Artillery, under orders for field service in Oregon. S. O. 5, Department of California, January 10, 1873.

De Witt, C., Assistant Surgeon.—To accompany Troop "K," 1st Cavalry, from Reno, Nevada, to Camp Bidwell, California, and on arrival, report to the Commanding Officer of that Post for duty at Camp Bidwell, or in the field. S. O. 12, Department of California, January 20, 1873.

Campbell, A. B., Assistant Surgeon.—Assigned to temporary duty in Chicago, Ills., to examine recruits. S. O. 21, War Department, A. G. O., January 25, 1873.

Weisel, D., Assistant Surgeon.—Assigned to duty at Fort Johnston, N. C. S. O., 14, Department of the South, January 22, 1873.

Medical Items and News.

Death of James L. Brown, M. D.—This well-known gentleman died suddenly from pneumonia, on the morning of Tuesday, February 4th, 1873, in the 42d year of his age.

At the stated meeting of the New York Academy of Medicine, held February 6th, 1873, Dr. Austin Flint, President, in the chair, Drs. T. Gaillard Thomas, E. R. Peaslee, Jas. Anderson, W. M. Chamberlain, and Jerome C. Smith, made eulogistic remarks concerning the deceased.

On motion of Dr. Thomas, a committee of three were appointed by the Chair to draft resolutions; consisting of Drs. Thomas, Chamberlain, and Smith. The committee retired, and subsequently presented the following resolutions, which were unanimously adopted:—

Whereas, it has pleased an all-wise Providence to remove from our midst our beloved fellow and associate, Dr. James L. Brown, therefore be it

Resolved, that by the death of Dr. Brown the Academy of Medicine has been deprived of a member, who, by his zealous and intelligent co-operation in all its labors, has proved himself a most valuable and esteemed associate.

Resolved, that the character of Dr. Brown, both in his professional and social relations, has always been such as to command our highest respect and warmest friendships, and that we regard his removal in the midst of an active and useful career, as an unusually great loss not only to ourselves, but to the profession at large.

Resolved, that we tender our most sincere and heartfelt sympathy to the family of Dr. Brown in their deep affliction.

Resolved, that a copy of these Resolutions be sent to the bereaved family, and that they be published in the medical journals of this city.

Austin Flint, M.D.,
President.
Wm. T. White, M.D.,
Secretary.

At a meeting of the students of the College of Physicians and Surgeons, New York, held February 5th, 1873, the following resolutions were adopted:—

Whereas, the students of the College of Physicians and Surgeons have learned, with deep regret, of the death of Dr. James L. Brown, Clinical Assistant to the chair of Obstetrics and Diseases of Women and Children in this Institution; therefore,

Resolved, that, while they recognize in that fact, the dispensation of an all-wise Providence, they appreciate the great loss which has thereby fallen on the College and the profession at large.

Resolved, that they also desire to express to their honored Professor of Obstetrics and Diseases of Women and Children, their appreciation of the loss he has sustained in the death of his able assistant.

Resolved, that a copy of these resolutions be transmitted to the family of the deceased, to Professor Thomas, and to one or more of the Medical Journals.

Resolved, that a committee of two be empowered to carry out the provisions of these resolutions.

George L. Peabody,
Arthur Mead Edwards,
Committee.

College of Physicians and Surgeons,
New York, February 5th, 1873.

February Meeting of the Medical Society of the County of New York:—At the next meeting of the County Society, to be held on the 24th inst., Dr.

John C. Peters is expected to read a paper having reference to the last (5th) revision of "The Pharmacopœia of the United States of America."

Members of the College of Pharmacy are invited to be present and take part in the discussion of the paper.

New York Academy of Medicine.—At the meeting Feb. 20, there will be "A Discourse on the Indications for General Pathology in Diseases of the Eye, with Illustrations by the Magic Lantern," by Prof. H. D. Noyes, M.D.

At the annual meeting of the Hudson County Medical Society, the following officers were elected for the ensuing year:—*President*, Dr. M. A. Miller; *Vice-President*, Dr. J. D. McGill; *Secretary*, Dr. Henry Mitchell; *Treasurer*, Dr. H. H. Abernethy; *Reporter*, Dr. J. E. Culver.

Jersey City Pathological Society.—At the annual meeting of this society, held January 9th, 1873, the following members were unanimously elected officers for the ensuing year: *President*, H. Mitchell, M.D.; *Vice-President*, F. G. Payn, M.D.; *Secretary*, T. J. McLoughlin, M.D.; *Treasurer*, J. D. McGill, M.D.; *Committee on Microscopy*, A. B. Watson, M.D., F. G. Payn, M.D., and J. D. McGill, M.D.

New Law Relating to Examination of Candidates for the Degree of Doctor in Medicine, Passed May 16, 1872.—

Section 1. The regents of the university of the State of New York shall appoint one or more boards of examiners in medicine, each board to consist of not less than seven members, who shall have been licensed to practise physic and surgery in this State.

§ 2. Such examiners shall faithfully examine all candidates referred to them for that purpose by the chancellor of said university, and furnish him a detailed report in writing of all the questions and answers of each examination, together with a separate written opinion of each examiner as to the acquirements and merits of the candidates in each case.

§ 3. Such examinations shall be in anatomy, physiology, materia medica, pathology, histology, clinical medicine, chemistry, surgery, midwifery, and in therapeutics, according to each of the systems of practice represented by the several medical societies of this State.

§ 4. The said reports of examinations, and the annexed opinions of the examiners, shall forever be a part of the public records of the said university, and the orders of the chancellor addressed to the examiners, together with the action of the regents, in each case, shall accompany the same.

§ 5. Any person over twenty-one years of age, of good moral character, and paying not less than thirty-five dollars into the treasury of the university, and on applying to the chancellor for the aforesaid examination, shall receive an order to that effect, addressed to one of the boards of examiners, provided he shall adduce proofs satisfactory to the chancellor, that he or she has a competent knowledge of all the branches of learning taught in the common schools of this State, and of the Latin Language, and that he has diligently studied medicine, not less than three years, under the direction of one or more physicians duly qualified to practise medicine, or has himself been licensed, on examination, by some medical society or college legally empowered to issue licenses or degrees in medicine.

§ 6. The regents of the university, on receiving the aforesaid reports of the examiners, and on finding that not less than five members of a board have voted in favor of a candidate, shall issue to him or her a diploma, conferring the degree of doctor of medicine of the university of the State of New York, which degree shall be a license to practise physic and surgery.

§ 7. The candidate, on receiving said diploma, shall pay to the university the further sum of not less than ten dollars.

§ 8. The moneys paid to the university, as aforesaid, shall be appropriated by the regents for the expenses of executing the provisions of this act.

§ 9. The regents may establish such rules and regulations, from time to time, as they may deem necessary to insure the faithful execution of the provisions of this act.

This act shall take effect immediately.

The Gorilla.—The Directors of the Museum of Bale, Switzerland, are merry over the acquisition of a skeleton of a gorilla, costing the sum of 4,000 francs. For several years past the visitor to the museums of Amherst College, Massachusetts, has noticed two splendid specimens of the gorilla—one being a wired skeleton, the other a full-grown dermatological subject. These were donated by a missionary in Africa, an alumnus of the college.

New Publications.

A Treatise on the Theory and Practice of Obstetrics. By Wm. H. Byford, A.M., M.D., Professor of Obstetrics and Diseases of Women and Children in Chicago Medical College, etc., etc. Second Edition, thoroughly revised. New York: William Wood & Co. 1873. Pp. 469.

The Pharmacopœia of the United States of America. Fifth Decennial Revision. Philadelphia: J. B. Lippincott & Co. 1873. Pp. 383.

Fistula, Hemorrhoids, Painful Ulcer, Stricture, Prolapsus, and other Diseases of the Rectum; their Diagnosis and Treatment. By William Allingham, F.R.C.S., Surgeon to St. Mark's Hospital for Fistula, etc. Second Edition, revised and enlarged. Philadelphia: Lindsay & Blakiston. 1873. Pp. 265.

A Treatise on Apoplexy, Cerebral Hemorrhage, Cerebral Embolism, Cerebral Gout, Cerebral Rheumatism, and Epidemic Cerebro-Spinal Meningitis. By John A. Lidell, A.M., M.D., ex-Professor of Anatomy in the National Medical College, Washington, D. C., etc., etc. New York: William Wood & Co. 1873. Pp. 395.

The Practice of Surgery. By Thomas Bryant, F.R.C.S., Surgeon to Guy's Hospital. With Five Hundred and Seven Illustrations. Philadelphia: Henry C. Lea. 1873. Pp. 984.

Illustrations of the Influence of the Mind upon the Body in Health and Disease. Designed to Elucidate the Action of the Imagination. By Daniel Hack Tuke, M.D., M.R.C.P., etc., etc. Philadelphia: Henry C. Lea. 1873. Pp. 415.

The Diseases of the Stomach. Being the Third Edition of the "Diagnosis and Treatment of the Varieties of Dyspepsia." Revised and Enlarged. By Wilson Fox, M.D., F.R.C.P., F.R.S., Physician Extraordinary to Her Majesty the Queen, etc. London and New York: Macmillan & Co. 1872. Pp. 236.

Family Thermometry; A Manual of Thermometry for Mothers, Nurses, Hospitals, etc., and all who have Charge of the Sick and of the Young. By Edouard Seguin, M.D. New York: G. P. Putnam & Sons. 1873. Pp. 72.

Original Communications.

SOME OF THE RECENT RESEARCHES IN PATHOLOGY.

BEING REMARKS MADE BEFORE THE MEDICAL LIBRARY AND JOURNAL ASSOCIATION OF NEW YORK.

By WM. B. NEFTEL, M.D.,

NEW YORK.

MR. PRESIDENT AND GENTLEMEN.—More than four years ago I had the honor of reading before this society a paper on a similar subject to the one I present this evening.* I then brought before the Society, and before the profession of this country, the results of the remarkable researches of my friend Prof. Cohnheim, with reference to inflammation and suppuration, and endeavored to demonstrate the emigration of the white blood-corpuscles through the intact walls of the blood-vessels. I mentioned on that occasion, that not alone the facts discovered by Cohnheim are of the highest importance, but that also his method will open a new field for further investigations and discoveries. I myself applied his method with some success, as related in the paper alluded to; but the most important application was made by Cohnheim himself for elucidating the mechanism of the embolic processes.† The doctrine of *embolic processes* has been so thoroughly studied from an anatomical, pathological, and clinical point of view by its great discoverer, Virchow,‡ that scarcely anything could be added by his numerous followers. Nevertheless, one point remained unexplained, viz., the mechanism of these processes—the modus operandi of emboli. Why do the consequences of embolism differ so widely? Why in some cases is embolism harmless, when in others it produces necrosis and gangrene, hemorrhagic infarctus or abscess? Though embolism may take place in every region and organ, yet in the brain and the extremities it almost always produces necrosis, while in the spleen and the lungs it calls forth hemorrhagic infarctus, which, however, does not occur in the muscles, in the skin, or in most of the glands.

To study the mechanism of embolic processes, Cohnheim chose such organs as would allow us to observe, under the microscope, the whole process from beginning to end. The tongue of the frog presents the most favorable conditions for such observations, on account of its easy access, its translucency, and the peculiar arrangement of its blood-vessels. The frog's tongue possesses two main arteries (accompanied by veins) which enter near its corresponding margins, traverse in a parallel direction its whole length, and communicate at the apex by an anastomosing arch. Each of these arteries gives numerous branches towards the margins of the tongue, but scarcely any towards the median portion. Another important anastomosis between both lingual arteries exists at the basis of the tongue. In order to call forth embolism, Cohnheim made use of an emulsion containing minute wax globules covered with soot. To produce emboli in the lingual branches, he injected the emulsion into the heart, and, to avoid unnecessary obliterations of other vessels of the body, into the internal section of an aortic arch, from which the carotid and lingual arteries alone originate. By applying during the injection a provisional ligature over the carotid, the mass could only enter the lingual artery.

Having injected the emulsion into the lingual arteries of a woorarized frog, Cohnheim observed that the column of blood in the embolized branch became immovable both in front and behind the embolus, and the main current passed through the collateral branches located more centrally. If the vessel were obstructed suddenly, the immovable column in front of the embolus consisted of aggregated red and white blood-corpuscles; but if the plugging were produced slowly, and the blood-corpuscles therefore had time to be driven out, the vessel contained only plasm, and perhaps a few white blood-corpuscles which stuck to the walls.

The changes in the circulation behind the embolus vary according to circumstances, whether or not the embolized vessel possesses, before its distribution into capillaries, an anastomosing branch with another artery. If it does, the effect of the embolus is perfectly insignificant, because the blood circulates through the collateral artery to the peripheric end of the plugged vessel, excluding only a small portion around the embolus. But when there is no such anastomosis (the embolized artery being a *terminal artery*—Cohnheim), then a complete stagnation of the circulating blood takes place, not only in the capillaries behind the embolus, but also in the veins of the corresponding region, until their confluence with a vein supplied from another source. From this latter vein the blood soon commences to flow, in an opposite direction, into the stagnating vessels, until the resistance from the accumulated blood equals the blood pressure in the vein. This retrograde circulation increases the accumulation of blood in the obstructed region, the result of which is hemorrhage. We observe then the emigration of white blood-corpuscles from the small and medium-sized veins and from the capillaries. From these latter, finally, extravasate also the red blood-corpuscles accumulating outside the vessels and forming the so-called hemorrhagic infarctus. Cohnheim demonstrated, by very ingenious experiments, that the cause of these phenomena lies entirely within the blood-vessels, the vital properties and functions of which undergo a complete change as soon as the normal circulation is arrested. On arresting the circulation in the entire tongue, by applying a loose ligature *en masse* at its basis, all the vessels become enormously dilated, but slowly contract again, and the circulation may be gradually restored if the ligature be taken off during the first day. If it be left during forty-eight hours, the vessels will remain dilated, the circulation therefore retarded, and from all the medium-sized and smaller veins, and from the capillaries, there will be noticed an excessive emigration of white blood-corpuscles, and, finally, of red ones from the capillaries. If the ligature remain still longer (four or five days), the circulation cannot be restored at all; the epithelium, the muscles, and other tissues undergo disintegration, and necrosis of the entire organ follows.

Cohnheim made similar experiments with different organs, especially the ears of rabbits and guinea-pigs, and obtained the same result. Everywhere four distinct stages developed themselves: dilatation of the vessels, emigration, extravasation, and absolute stasis. In all these experiments, the prolonged arrest of the normal circulation at first calls forth an enormously large emigration of white blood-corpuscles, characterized by œdema of the ligatured part, and followed afterward by the emigration of red corpuscles, pre-

* MEDICAL RECORD, July 15th, 1868.

† Dr. Cohnheim. Untersuchungen über die embolischen Processe. Berlin, 1872.

‡ R. Virchow. Gesammelte Abhand. Frankfort, 1856, p. 219.

senting all the features of hemorrhagic infarctus. Colnheim proved, at the same time, that ligature of the organs, with exclusion of the vessels, does not produce the described phenomena.

The ultimate fate of the embolized portion may be as follows: Either the embolus organizes itself, becomes adherent to the wall of the vessel, and exercises no injurious effect upon the corresponding tissues—as is the case when an anastomosing branch enters the plugged vessel behind the embolus, and thus restores the normal circulation.—or, when no such anastomosis exists, the part behind the embolus undergoes either a necrobiotic process (dry or moist gangrene, or simple softening), or hemorrhagic infiltration.

Thus we find in the human subject the conditions favorable for the first sequela, when an artery is embolized below, or in the circle of Willis, or when the seat of embolism is one of the larger branches of the pulmonary artery. We find, further, such a favorable arterial arrangement in the skin, in the muscles, in the fibrous and serous membranes, in the intestinal canal and mesentery, in almost all the glands, in the bladder, sexual organs, bones, in the heart, choroid and iris, in the walls of the respiratory organs, &c. All these organs are so richly provided with arterial anastomoses that the consequences of embolism of a single artery are transitory and insignificant, just as would be its ligation. There is, however, one rare exception, when even in the organs above mentioned embolism will be followed by a permanent disturbance in the circulation and nutrition of the affected organ (gangrene). This happens when, besides the main artery, all its collateral branches become embolized, producing therefore the same effect as if the main artery were a terminal artery. Thus can be explained the occurrence, though extremely rare, of gangrene in the intestinal canal, or in the extremities after multiple embolism in the mesenteric artery, or in the arteries of the extremities.

The organs that possess real terminal arteries, and in which therefore the two last sequelæ—necrobiosis and hemorrhagic infarction—do occur, are the spleen, the kidney, the brain, the retina, and, to some extent, the lungs. In the latter organ the circulation may be completely restored through the interlobular collaterals near the hilus; and here, therefore, infarctus cannot occur, while it may take place at the periphery, where the arteries become terminal. In these last-mentioned five organs, the result of embolism is necrobiosis (without decomposition accompanying gangrene of the parts exposed to atmospheric influence), whenever the conditions are unfavorable to the formation of a hemorrhagic infarction. Thus hemorrhagic infarction does not take place whenever there is an obstacle to the retrograde circulation in the veins, the latter being the real cause of the infarction. This is the case, for instance, when the law of gravitation acts against the retrograde circulation, or in localities where the veins possess valves. Again, whenever the embolus obstructs only partially the artery, an incomplete circulation continues behind the embolus, thus preventing the stagnation of blood and the retrograde circulation—the two necessary conditions for a hemorrhagic infarction. Lastly, a very feeble action of the heart may also prevent the accumulation of blood behind the embolus and the subsequent infarction.

In accordance with the fact that infarctus is caused only by the retrograde circulation in the obstructed veins, it must necessarily appear several days after embolism has taken place. We can easily understand also why the apex of the infarctus does not correspond to the embolus, but to the obstructed vein from which it has originated.

Embolic abscesses are produced by bodies that not only act mechanically, but are also endowed with infectious properties. By injecting minute particles of putrid meat, Colnheim invariably called forth these abscesses, because sooner or later inflammation and suppuration set in around the emboli.

In human pathology we find in the lungs and liver embolic abscesses of a larger size than in all the other organs, where only miliary abscesses are to be found, because in the lungs and liver the emboli originate from the large thrombotic masses of the veins of the extremities and of the abdomen, whereas the emboli of the other organs develop themselves from the minute endocarditic vegetations.

In accordance with Colnheim's experiments, we find in the lungs both embolic infarctus and abscesses. But while the former depend on pure mechanical emboli of terminal arteries, they must necessarily take place at the periphery of the organ, and present a conical shape; the abscesses, on the contrary, may be found in every part of the organ, and always present a globular form.

Chlorosis.

I now proceed to examine *chlorosis*, which has generally been considered as a primary pathological condition of the blood, and by some authorities of this country as a nervous affection. Both these assumptions are erroneous. Chlorosis, according to Virchow,* is based on a congenital, or early acquired arrest of development of the heart and large arterial trunks, especially of the aorta. This primary pathological condition is almost always accompanied by an abnormal development of the sexual apparatus. In the majority of cases the sexual organs are also arrested in their development, especially the ovaries and the uterus, and the menstrual flow is very scanty (amenorrhœa). In some cases, however, an excessive development of the sexual organs occurs with profuse menstruation.

The small size of the heart, which in the earliest infancy corresponds to the abnormal narrowness of the aorta, becomes secondarily hypertrophied from its increased activity in propelling the blood through the narrow canal. This hypertrophy of the heart can also be accompanied by its dilatation, under conditions unfavorable for the nutrition of this organ. Similar anomalies of the heart and aorta are occasionally met with in the male, who may therefore also be affected with chlorosis. If the production of blood be increased in persons with such a narrowness and small capacity of the blood-vessels, the blood-pressure in the aortic system must necessarily increase to a high degree, not only towards the heart, but also towards the periphery. Indeed, during the last ten years Virchow found at the autopsy of all those affected with hemorrhagic diathesis, the above described condition of the vascular system. This certainly explains the excessive menstruation in some chlorotic persons, and also the frequency of chronic ulcers of the stomach in those affected with chlorosis. In regard to the etiology of chronic ulcers of the stomach, it is known that they originate from hemorrhagic infarctions in the walls of this organ. Under normal conditions, the free hydrochloric acid of the gastric juice, being constantly neutralized by the alkali of the circulating blood in the numerous blood-vessels, cannot affect the walls of the stomach. But as soon as the circulation ceases, for instance, in an infarcted place, the free acid acts upon it (self-digestion), producing an ulcer. Therefore, according to the exact investigations of Virchow, the hemorrhagic dia-

* R. Virchow. Ueber die Chlorose. Berlin. 1872.

thesis, purpura, and analogous conditions, are based upon the narrowness of the aortic system and the high pressure under which the blood circulates, thus causing ruptures of the vessels and hemorrhages.

In chlorosis the aorta and the large arterial trunks are not only very narrow, but their walls are exceedingly thin, especially the internal and middle coats. In full-grown chlorotic women, the calibre of the aorta is so small that the little finger cannot be introduced into it. Besides, there is very often a great irregularity in the origin of the arterial trunks, especially of the intercostal arteries from the thoracic aorta. Finally, Virchow very frequently found small indurated protuberances on the internal coat, and especially on that of the abdominal aorta.

It is a general law in pathology that those organs which present an imperfect and faulty anatomical structure exhibit a great disposition to morbid processes, and in chlorotic persons we find such a morbid disposition to various affections of the organs of circulation. The most frequent structural change found even in young chlorotic persons is an extensive fatty metamorphosis of the internal coat of blood-vessels, leading to superficial ulcerations (without suppuration). Still more important, though not so frequent, is the fatty degeneration of the middle coat and of the heart, which explains the occurrence of spontaneous rupture of the large blood-vessels in chlorotic persons. But the most important affection met with in chlorosis is valvular endocarditis. In the majority of fatal cases of endocarditis in earlier life we find a primary undeveloped condition of the aorta, not only in women, but also in men.

The researches of Virchow also explain the frequent complication of chlorosis with puerperal endocarditis and all its consequences, and especially with the most malignant embolic processes. The broken-off detritus of the valvular vegetations are carried by the circulating blood, and produce numerous emboli in single organs, or simultaneously in the kidneys, the spleen, the retina, and choroid. This latter affection was formerly described simply as puerperal ophthalmia. Very probably the puerperal inflammatory rheumatism depends on embolism in the synovial membrane, resulting from such a malignant endocarditis. In young chlorotic persons there exists also a disposition to tuberculosis, but its mechanism is not yet sufficiently elucidated.

Quite recently Quincke* found the amount of hæmoglobin greatly diminished in chlorosis, namely, 5.4 per cent. the normal quantity being 15.5. per cent.

I will state here that I found in a considerable number of chlorotic persons an affection of the acoustic apparatus that has not been mentioned by any author. I repeatedly observed† that after thirty years they suffer from hardness of hearing, slowly increasing to deafness, and sometimes accompanied by tinnitus aurium, vertigo, and other cerebral symptoms. The galvanic reaction of the auditory nerve shows a high degree of torpor. The menstruation in such patients is almost always very profuse. In other cases, again, the deafness in young chlorotics appears suddenly with acute symptoms resembling Menière's disease, and is characterized by hyperæsthesia of the acoustic nerve. I presume that in these cases a hemorrhage in the labyrinth has taken place, owing to the described disposition of such patients to hemorrhages. Lastly, I am inclined to ascribe some paralytic conditions, especially those known as hysterical and infantile paralysis, to hemorrhages in the nervous centres of chlorotic persons. But this latter assumption has yet to be corroborated by more numerous observations, and especially by post-mortem examinations.

From this sketch of Virchow's researches on chlorosis, it is evident that the affection is almost always congenital, at least acquired in early life, and, strictly speaking, is therefore incurable. But there is no doubt that the educated physician can do a great deal and preserve the patient in a state of comparative health, by improving his nutrition, arresting the further development, and even preventing most of the dangerous complications of chlorosis.

Infectious Diseases.

I wish to call the attention of the association to those *parasitic vegetable organisms* which play so important a part in infectious diseases. It is supposed, with a great deal of probability, that in these diseases the fungi excite a process analogous to fermentation, based on the action of these minute organisms, as has been demonstrated by the great discoveries of Pasteur. This striking analogy justifies the name of zymotic diseases, by which the infectious diseases are now often designated.

But in taking up this subject, to which I myself paid much attention, I will omit the numerous researches of Hallier and others, as they are not based on exact scientific observations. I will mention only the results of investigations made with strictest methods by competent observers.*

The first impulse to these researches was given by the investigation of epidemic diseases in plants and insects, where the cause or the contagion was found to be microscopic fungi. In the disease of the grape a fungus, Oidium Tuckeri, is found to inhabit and destroy the grapes. The cause of the disease of potatoes is also a fungus, Peronospora infestans. The epidemic disease of the silkworms is caused by a parasitic fungus, Botrytis Bassiana, which lives on the blood and tissues of the insect, thus causing its death. The epidemic among the common flies happening so often in the fall, is caused by the development of a fungus, Empusa Muscæ, in the living fly. Schoenlein was the first who discovered a microscopic fungus as the cause of a disease in man, and showed that the Achorion produces a characteristic affection of the skin (favus). Since that time several other fungi were found to be the source of some local cutaneous diseases, as for instance the Trichophyton tonsurans, the fungus producing herpes tonsurans and sycosis; the Microsporon furfur—the fungus of pityriasis versicolor, and the Oidium albicans—the fungus of aphthous affections. These vegetable organisms, but especially those which excite infectious diseases, belong to the lowest forms of vegetable life. They do not possess the green vegetable coloring matter (chlorophyte), the function of which is to form the organizable combinations of carbon with hydrogen, oxygen, and nitrogen from the air, water, and inorganic mineral matter. Their life therefore depends entirely on the presence of preformed organic substances, plants or animals. They vegetate either in living organisms, and are called parasites, or in dead ones undergoing decomposition and putrefaction—Saprophytes. One group of these vegetable organisms does not strictly belong to real fungi; it i composed of very minute bodies of a still simpler organization, and classified under the name of Schizo-

* Virchow's *Archiv*, 1872, B4. LIV., p. 537.

* F. Stendener. Ueber pflanzliche Organismen als Krankheitserreger. Saml. Klin. Vortrage. Leipzig, 1872.

mycetes. They have a globular, oval, or cylindrical shape, and multiply by continually dividing into two in a right line, never producing branches. They are either quite immovable, or else exhibit a very vivid or an oscillating motion. Their growth is in a linear direction, forming long rods or chains of small globular cells, which sometimes are conglomerated by a gelatinous mass into a large, irregular, immovable lump called Zoogloea. In this latter condition the cells still continue to multiply. They seem not to possess special organs of reproduction, and the preservation of the species is effected through the evaporation of fluids in which the Schizomycetes exist. In this way they enter the air with the vapor, and there remain suspended until they come in contact with suitable fluids, in which they recommence to multiply by division.

These Schizomycetes are bearers of the different ferments by means of which they produce peculiar transformations in the fluids in which they vegetate. They transform alcohol into acetic acid, sugar of milk into lactic acid, and produce in albuminous substances decompositions called putrefaction.

From a pathological point of view the most important of these Schizomycetes is the *Bacterium Termo*, which excites and keeps up putrefaction of albuminous bodies. By the division and growth of its cells it appears under different forms, as Monas crepusculum, Leptothrix, Zoogloea, which, however, are only different stages of development of the same species. Every fungus we meet in diseases is not to be considered a parasite and the cause of the disease. We often find Aspergillus, Penicillum, Mucor, etc., in external or internal cavities, in dead tissues and stagnant secretions of the body, for instance on the tympanic membrane, on ulcerating surfaces of the lungs; but in these cases the fungi have not called forth the pathological process, though their presence favors the secondary decomposition. In other cases, however, they must be considered as the primary cause of the disease. For instance, Traube demonstrated that through a catheter, germs of Schizomycetes have been introduced into the bladder, where by their further development they produced putrid suppuration of the bladder and ureters, and abscesses in the kidneys, in which at the post-mortem movable Bacteria were found.

With regard to the infectious diseases, I shall commence with pyæmia and septicæmia, in which, quite recently, Klebs has found a vegetable organism, called by him Microsporon septicum, that must be considered as the real cause of both these diseases. Klebs, who is Professor of Pathological Anatomy, and a pupil of Virchow, elucidated the mode of propagation of this fungus, and its manner of action upon the system, and demonstrated the correctness of his assertions by very exact methods and ingenious experiments. He found the different forms of Bacterium, Leptothris, Zoogloka, belonging to the same species of Schizomycetes, in the thin and purulent secretions of wounds and granulating surfaces. Thence they penetrate into the juice-conveying canals of the connective tissue, where they excite inflammation and suppuration, and also into the marrow of the bones, producing traumatic osteomyelitis. Further, by destroying the walls of the blood-vessels they enter into the circulation, causing inflammation of the internal coat, thrombosis and embolism. They lastly excite the decomposition of the emboli, and form abscesses. The experiment made by Klebs to prove the correctness of his views is very conclusive. He takes the secretions of wounds containing numerous fungi, filters them through a porous jar, and injects hypodermically into animals the filtered fluid freed of Microsporon. No pyæmia follows, and all the animals recover; whilst the unfiltered fluid that contains the fungi invariably produces all the characteristic symptoms of pyæmia and septicæmia, and kills the animals. Klebs' experiments show further the pyrogenic effect of the fungi, and the anatomical and pathological identity of pyæmia and septicæmia.

The researches of Davaine and others have elucidated the fact that the malignant carbuncle of animals and men is produced by the penetration of vegetable organisms (Bacteria) into the circulation, causing chemical decomposition of the blood analogous to fermentation.

A fungus is also the cause of diphtheria, as proved by the observations and experiments of Buhl, Huter, Oertel, and Nassiloff. From the primarily affected locality the Schizomycetes enter into the tissues and the blood, causing decomposition of the fluids and solids of the system. The experiments on animals show conclusively that these vegetable organisms are the real bearers of the contagion.

Lately, Prof. Cohn, of Breslau,* has demonstrated that small-pox is caused by a Schizomycete, called by him Microsphæra (Kugelbacterie).

It is probable that other infectious diseases are also produced by some vegetable organisms, but they have not yet been demonstrated by exact methods. According to the researches of Tiegel,† Cohn, and others, the action of fungi depends on the products of decomposition called forth by them. Thus Bergmann and Schmiedeberg discovered in putrid wounds a specific poison, sepsin, which, being introduced into the system, calls forth the symptoms of septic fever. Tiegel thinks, therefore, that the Microsporon septicum of Klebs produces sepsin, that gives rise to the symptoms of septicæmia.

CARCINOMA.

I purpose now to bring before you another subject of great theoretical and practical interest, namely, the *structure, development and origin of carcinoma*.‡ It is only since the first researches of Virchow§ that we are enabled to distinguish with certainty the carcinoma from other malignant neoplasms. According to Virchow, with whom all pathologists now agree, the characteristic histological structure of a real cancer consists of a stroma of connective tissue, forming, as it were, alveoli, in which are embedded conglomerations of cells of an epitheloid character without intercellular tissue. Only the stroma contains blood-vessels and lymphatics; the aggregated cells of the alveoli, like all other epithelial formations, are entirely destitute of these vessels. The number and size of the blood-vessels in the stroma vary considerably. In some cancers the vessels are so numerous that they are called fungus hæmatodes. But the greater portion of tumors that formerly were thus designated are sarcomas.

In microscopical preparations, the cells contained in the alveoli have to be brushed out to allow an easier examination of the stroma. We are then able to ascertain that the alveoli are not perfectly isolated and closed cavities, but they connect with each other; so that the whole tumor can be compared to a sponge, the pores of which are filled with cancer cells. In cancers called Scirrhus we find the stroma consisting of abundant and resistant connective tissue, with few cellular elements.

§ R. Virchow, Zur Entwickelungsgeschichte des Krebses. Virchow's Archiv, Bd. I. p. 94.

In medullary cancers, the stroma contains a very small amount of connective tissue, and forms numerous and large alveoli, overfilled with cells. In some cases the stroma ossificates, or contains calcareous deposits, fatty, mucous tissue, or pigment, whence the different varieties of carcinoma, ossificans, petrificans, lipomatosum, myxomatosum, melanoticum. Lastly, the stroma may exhibit the structure of a sarcoma, a variety called carcinoma sarcomatosum.

The cells of carcinoma have nothing characteristic, certainly nothing specific in their microscopic appearance. They are mostly of a polymorphous shape, from their conglomeration within the alveoli, and form the so-called cancerous bodies. They do not possess a cell-membrane, and consist only of protoplasm containing a very distinct, large nucleus, and one or several nucleoli. Examined on the heated objective and in serum, the fresh cancer cells exhibit a slow motion, as observed by Waldeyer and Carmalt.* From a cut surface of a carcinoma the so-called cancer juice can be obtained; a valuable sign, as it contains only the cancer cells pressed out from the opened alveoli. The tissues surrounding the carcinoma and the single cancerous bodies are infiltrated with small amœboid cells. These are white blood-corpuscles that emigrated from the blood-vessels, a phenomenon always accompanying inflammatory action.

Carcinoma, after having reached a certain degree of development, undergoes different regressive metamorphoses, resulting in ulcerative and various destructive processes. These metamorphoses commence in the stroma, and cause the secondary fatty degeneration of the cancerous bodies. The cancer-cells sometimes undergo horny and colloid metamorphoses, whence the varieties of carcinoma keratodes and colloides. As a general rule the cancerous growths form tumors; in some exceptional cases, however, they are flat, and lead to the incurable superficial *ulcus rodens*.

In regard to the development of carcinoma I shall first mention Remak's theory. Among the numerous discoveries contained in his great work on Embryology, there is one that has since become a fundamental law of modern histology. He found that as soon as the embryonic cells are differentiated into the various germinal layers, they remain so forever. An epithelial cell, for instance, can never be transformed into connective tissue cell, and *vice versa*. We must therefore distinguish four large groups of such primitive tissues, namely, the epithelial, nervous, muscular, and connective tissues. Applying the same law to pathological productions, Remak concluded that cancerous growths, which are epithelial formations, must necessarily develop themselves from a preformed epithelium. But soon Virchow's theory became generally adopted, according to which, carcinoma, like all other new formations, develops itself from the proliferation of the cells of connective tissue. In 1865, Thiersch revived Remak's theory, but only with reference to epithelioma. The important researches of Waldeyer fully confirmed Remak's views, and contributed new and valuable facts. He demonstrated that the cancer cells possess all the characteristics of real epithelial cells. Like these, they are not connected with each other, but only juxtaposed. They do not possess intercellular substance, and never carry blood-vessels and lymphatics. Waldeyer demonstrated further the direct development of cancer cells from the proliferation of preformed epithelial cells. These latter proliferate very rapidly by division, producing irregular, atypic accumulations of cells. In this way originate the so-called cancerous bodies, which again continue to grow into the surrounding connective tissue, often through the lymphatis spaces, thus involving a whole organ into the cancerouc degeneration. The primary cancer, therefore, does not appear as a circumscribed and limited tumor, but rather as a diffused infiltration of the whole organ; a very valuable sign, on which depends the well-known immobility of real cancers. Finally, the cancer cells, through the lymphatics (discovered in carcinomas by Schroeder van der Kolk), and through the blood-vessels, are carried into distant places, producing there cancerous emboli and secondary metastatic deposits. It is probable that the spontaneous motion of the cancer cells is favorable for these metastases. The secondary cancers, unlike the primary ones, present therefore a distinct circumscribed nodule or tumor, which may continue to grow.

The result of Waldeyer's researches can thus be summed up: The cancer cells and cancer bodies of carcinoma always originate from the pre-existing real epithelium of the system, while its stroma originate from the connective tissue. We must, however, make a *strict* distinction between the real or true epithelium and the so-called endothelium lining the serous membranes and the internal surface of blood-vessels and lymphatics. The endothelium, according to His, are flattened connective-tissue corpuscles, and are therefore in no relation to the development of carcinoma.

Cancer cells, being epithelial structures, are not connected together, and this fact alone can serve as a characteristic distinction between carcinoma and sarcoma, the cells of the latter being organically connected between themselves and with the stroma.

Finally, according to Waldeyer, there exists no difference between carcinoma and epithelioma or cancroid, neither from an anatomical nor clinical point of view, and every epithelial neoplasm may become carcinomatous. I shall mention two other theories of the development of carcinoma, the one given by Koester,* according to which carcinoma develops itself from the proliferation of the endothelium of the lymphatics, and the other theory of Classen † and others who admit the development of cancer cells from the emigrated white blood-corpuscles. Both these theories have been completely refuted by the classical researches of Waldeyer.

I cannot leave this subject without touching upon a question of the highest practical importance, namely, the *origin of carcinoma*. Is such a tumor always the expression of a constitutional affection, of a dyscrasia, or diathesis? Those who, like myself, have observed the emaciated, cachectic-looking cancerous patients in hospitals, and have at the post-mortem found the identical morbid process in the different tissues and the most distant organs, will certainly be impressed by the idea of a constitutional origin of cancer. However, under the influence of Virchow's doctrines, and especially after having worked for a considerable time under the guidance of this great pathologist, I gradually came to the conviction that even malignant tumors may originate locally, and only consecutively call forth the generalization of the disease and the constitutional affection. Subsequent observations made by me in private practice fully corroborated this assumption. I possess notes of a considerable number of cases which I followed up from the first symptoms of the disease until the fatal termination. I could ascertain, beyond any doubt, that the most malignant

† Ueber ein Cancroid der Cornea und Sclera. Virchow's Archiv, Bd. L., p 56.

tumors originated from a purely local cause in robust persons without the least hereditary disposition. This is the reason why only those organs are primarily affected by carcinoma which are the most exposed to mechanical and chemical irritations; for instance, the lips, tongue, œsophagus, stomach, rectum, uterus, breast, testicles, etc. The local cancerous affection of these organs becomes secondarily generalized through the lymphatics and the veins.

Even the so-called cachectic appearance of the patients develops itself in the latter stages of the disease. The patients affected with carcinoma may at first look very healthy. The cachectic appearance follows afterwards, in consequence of the pain, the ulcerative processes, and especially from the absorption of cancerous detritus, which act in the manner of deleterious excrementitious matter.

If carcinoma be originally a local affection, why is it not always cured by extirpation of the tumor, but, on the contrary, is usually followed by a relapse of the disease? The answer is quite simple. On examining microscopically, after the extirpation of a tumor, the neighboring so-called healthy parts, we invariably find them already involved in the cancerous degeneration. The remaining cells seem to increase their proliferating activity and thus accelerate the fatal end. The so-called relapses of cancer are therefore nothing else but a continuation of growth of the neoplasm.

THE "ARTERY CONSTRICTOR,"

WITH ADDITIONAL CASES.

By S. FLEET SPEIR, M.D.,

SURGEON TO THE BROOKLYN CITY HOSPITAL, ETC.

SINCE the cases last reported in the MEDICAL RECORD, I have had the opportunity of using the Artery Constrictor in the following cases.

Amputation of the Forearm for Disease of the Metacarpal Bones—Application of the Artery Constrictor to the Ulnar and Radial Arteries—Union by First Intention.

On the 23d of April, 1872, I amputated the forearm of a patient under the care of Dr. F. C. De Mund, with whom I had previously seen the patient in consultation. He had suffered during several months from a chronic inflammation of the metacarpal bones, accompanied by intense pain. His health and strength failed rapidly; and there being no prospect of restoring the joint to usefulness, it was deemed best to amputate, which I did by a flap operation, and applied the constrictor to the ulnar and radial arteries. The interosseous artery I endeavored to close by torsion, but the artery gave way, and I was obliged to apply a ligature; and being anxious to secure union by first intention, I selected an extremely delicate but strong silk ligature, and tied the vessel very tightly, hoping that it would not interfere with rapid union; and it seems it did not. The wound was brought together by silver wire, and bandaged. The wound united by first intention; the patient went out the day after the operation, and continued to go out every day after; calling at my office on the third day (a distance of five miles from his home). Dr. De Mund took charge of the dressing of the stump, and gives me the following particulars: "The day following the amputation of Mr. D.'s forearm I found him more comfortable than he had been for several weeks, the arm so easy that I did not disturb the dressing. The third day after the amputation I undid the bandage, but did not disturb the lint that was placed upon the stump, owing to the fact that there was little, if any, discharge. The fourth day I removed the lint, soaking it first with tepid water, and found that the parts had united by first intention with the exception of one place, where a ligature was placed, the artery being so small that you deemed it advisable to use one." In this case the delicate ligature placed upon the interosseous artery did not seem to interfere with the healing process as much as in some other cases. I have used the ligature and the artery constrictor side by side in several cases, for the purpose of determining the advantages of one over the other, when used in the same wound and under the same circumstances.

Amputation of the Forearm—Constriction of Ulnar and Radial Arteries—Union by First Intention.

Michael C——; 14 years old; Ireland; admitted September 12th, 1872, to the Brooklyn City Hospital, with a badly lacerated wound of the hand, and compound dislocation of the wrist-joint; soft parts of the lower portion of the forearm much contused. I performed amputation in the middle third of the forearm. The radial and ulnar arteries were closed by the artery constrictor, and the interosseous artery ligated with the ordinary silk ligature. The patient did very well after the operation, in spite of a strong tendency to "mania a potu," which was controlled by hydrate of chloral. There was some venous oozing, eight hours after the operation, from a large superficial vein which had bled obstinately during the operation. This was readily checked by a firm bandage. The wound healed by the first intention, except at one point, there being a slight discharge at the point of exit of the ligature. Ligature and sutures removed on the thirteenth day.

This history and the following are furnished by Dr. Gillett, resident surgeon of the Hospital.

Amputation of the Arm—High Bifurcation of the Brachial Artery—Artery Constrictor applied to the Larger Artery, and a Ligature to the Smaller Artery.

Fred. B——, aged 26; England; tinsmith; admitted September 16th, 1872, to the Brooklyn City Hospital, with compound fracture of the ulna and radius, and with extensive laceration of the forearm and arm. I amputated the arm twenty-four hours after admission. The bifurcation of the radial and ulnar arteries was high up in the middle arm. I applied the artery constrictor to the larger branch of the brachial, and a ligature to the other, which was smaller. There was some contusion at the point of amputation, and some swelling and inflammation of the arm followed for three or four days after amputation. Notwithstanding this, the wound healed kindly, uniting firmly without discharge from the side on which the constrictor was used, but presenting a continual discharge from the point of exit of the silk ligature. This ligature remained very firm until the twenty-first day, when it was removed, leaving a sinus from which there was a slight discharge for several days longer. The patient left the hospital at the end of the third week.

Constriction of Femoral and Profunda Arteries—Chronic Synovitis of three years' standing—Amputation in Upper Third of Thigh—Service of Dr. S. Fleet Speir, Brooklyn City Hospital.

Mark O'Malley, aged 23, Ireland, seaman, admitted January 24th, 1872. Patient fell down a flight of steps, striking his knee violently upon the sidewalk, from which time he has been troubled with pain in

the knee, which has continually increased in severity. The injury was received just before embarking on a voyage to China, and while in port, and during his voyage home he was confined to his berth for nearly five months. When admitted to this hospital he was very much exhausted, having been obliged by the pain to sleep in a sitting posture for nearly a month. Extension, by means of adhesive strips and pulleys, with weights attached, was applied, and the patient put upon tonics, and a hypodermic injection of morphia at night. He slowly improved up to the first of May, when a large abscess formed, which was opened by valvular incision. After this there was a continual discharge from the knee-joint, up to the time of the operation, October 5th, 1872.

A consultation of the visiting surgeons being called, it was decided that, as the disease appeared to be progressively attacking the bone, higher amputation should be performed.

The leg was amputated in the upper third of the thigh, by Dr. Speir. The bone was somewhat softened, and there was a good deal of hemorrhage from the nutrient artery, which was enlarged. The femoral and profunda arteries were tied by the constrictor, and the edges of the wound brought together by silver-wire sutures. On the fifth day some hemorrhage supervened, on the removal of a firm clot, which seemed to have been formed by oozing from the nutrient artery, and which was permitted by the looseness of the dressing. A firm bandage was applied; the hemorrhage was checked, but for several days there was a bad discharge, sanious in character, having the appearance of the breaking down of a clot. The patient has had a pulse ranging from 120 to 140 ever since the operation; has had repeated hemorrhages from the nose, but withal feels much stronger and better than before the operation.

October 29th.—The wound is nearly healed; no discharge. The sutures were removed on the 20th.

The above is the history as handed me by Dr. Gillett, the resident surgeon. I may add that in this case the femoral vein bled very profusely during the operation, and that I applied the constrictor to it with the same effect as upon the arteries. The nutrient artery was very large, and sent out a large jet of blood. Pressure only partly controlled it, and there was still some oozing from it when the wound was closed, but it was hoped that pressure on the stump would stop it, and I preferred to trust to this rather than keep the patient longer under the anæsthetic. There was a third artery of some size, which was closed by the use of the constrictor, but in a different method from that used on the others, viz.: I constricted this vessel until I was satisfied I had cut the internal and middle coats; and then, while the artery was still in the grasp of the tongue of the constrictor, I applied the torsion forceps to it and gave it several turns, in this way producing the invagination of the internal and middle coats, which, in the ordinary application of the instrument, the constrictor does of itself. I mention this as a method of effecting torsion with a certainty of dividing the inner coats at the exact point desired, with no risk of splitting them higher up than might be wished. It may be found of service to those who are partial to torsion.

Success in the application of the constrictor depends upon the invagination of the internal and middle coats of the artery. It is not enough to simply divide these coats; they must be thoroughly invaginated, and a constrictor which does not divide and thoroughly invaginate the internal and middle coats (tried upon a dead artery), should be returned to the instrument-maker as imperfect. The outer coat should be left uninjured. This last is not so important in amputations as for cases of aneurism, for if the invagination be complete, success is certain. The test of a good instrument, then, is its power to invaginate the internal and middle coats without injuring the external coat of the artery. I hope that any one desiring to make use of the constrictor will apply this test on a dead artery, and become familiar with its operation, before applying it to the living vessel, and thus make sure the instrument is a perfect one.

Temporal Artery closed by the Artery Constrictor.

Peter K——, aged 20; January 8th, 1872. Came to the "Brooklyn Tumor and Cancer Infirmary," with an encysted tumor of five years' standing, situated in the temporal region, covering over and involving the temporal artery. The tumor was at first supposed to be a simple encysted tumor, but on examination with the microscope it proved to be malignant. In the operation for removal I found the temporal artery so embedded in the tumor that it had to be severed. The artery constrictor was applied to it, and the operation terminated with but little loss of blood. The wound healed by granulation.

Amputation of Breast for Cancer, with Application of Constrictor.

Mrs. E. P——, aged 63; admitted June 24th, 1871, to the "Brooklyn Tumor and Cancer Infirmary," with extensive cancer of the right breast. The tumor began about three years ago, after a blow upon the breast. At first it was very small, but has been growing slowly until it has involved nearly the whole gland, and is very large, with a great deal of heat and pain, a bluish discoloration, and with a tendency to ulcerate at one point; nipple retracted, gland in axilla indurated and painful. Local and constitutional treatment was given her, but the pain continuing, and the disease progressing steadily, she returned to the Infirmary January 10th, 1872, to have the breast amputated. The breast was very large, and I found the vessels exposed in the operation correspondingly large. They were all closed by the artery constrictor, and the wound brought together by silver-wire sutures, and union by first intention occurred along the whole track of the wound, with the exception of one small point where a superficial abscess formed, and this healed by granulation.

I have used the constrictor in several other cases of amputation of the breast, two of which united by first intention; but it is not worth while to multiply cases in which the vessels can be so easily closed by torsion, or even pressure alone, when they are small.

Constriction of the Right Primitive Carotid for Aneurism at its Root (Brasdor's operation), performed by Dr. James B. Bell, *of Maine.*

December 29th, 1871, Dr. J. B. Bell, of Augusta, Maine, wrote me that a few weeks previously he had constricted the right primitive carotid artery of a lady, for aneurism at its root (Brasdor's operation). He says: "The operation was entirely successful, healing by first intention, although ten days afterwards there was, for two days, a little discharge of pus.

"I applied it (the artery constrictor) fifteen minutes, screwing it up until very considerable resistance was felt. This reduced the artery to a mere packing-thread. In this case the temporal artery did not lose its pulse at any time, and the next day there was pulsation in

the carotid above the wound, all, as I believe, through the basilar arteries, and perhaps the thyroid."

November 16th, 1872. Dr. Bell writes me that the case is still doing well. It appears to me that fifteen minutes was a longer time than necessary to leave the constrictor on the artery, and it is interesting to see that after so long an application there was union by first intention, showing that the external coat must have been left uninjured.

GLAUCOMATOUS INFLAMMATION OF THE FELLOW EYE,

RESULTING FROM

THE LINEAR EXTRACTION OF A TRAUMATIC CATARACT; EARLY IRIDECTOMY; CURE.

By O. D. POMEROY, M.D.,

NEW YORK.

Mrs. P., aged 40, on the 25th of September, 1871, was attempting to remove a carpet-nail from a stairway, when it suddenly flew out, and striking the left cornea, penetrated it, wounding the lens; the latter at once absorbed aqueous humor and swelled to a considerable size, with flakes of lens matter detached and falling into the anterior chamber, as is the case in a somewhat violent needle operation. I saw the patient four days after the injury (she being attended throughout by the family physician).

There had been considerable pain, and atropine had been used by the physician, with partial relief. Ordered warm water to bathe the eye, and the atropine to be continued. The case remained reasonably quiescent for about three weeks, when, noticing some symptoms of tension of the globe, I performed paracentesis, but on the next morning the tension was the same as at first, with increased pain. Three days after this date, feeling satisfied that this line of treatment was inefficient, I extracted the lens piecemeal through a linear wound made by a narrow Graefe's knife. It was removed pretty cleanly by pressure alone, without difficulty or undue violence, and a retentive bandage applied over both eyes. On each subsequent day until recovery, the lids were opened and atropine instilled.

On the fourth day after the operation, the right, or well eye, was uncovered, and the patient exclaimed that she could not see well; that the sight was clouded. I examined and found a dilated pupil, and, with the ophthalmoscope, discovered opacities in the vitreous humor, with vision about ½. Naturally I was somewhat surprised, as the patient had made no complaint of pain, or anything more than the uncomfortableness which a bandage might produce.

The tension was only slightly increased; there was some ciliary and conjunctival injection. Although the time was evening, iridectomy was at once done by the aid of gas, a kerosene lamp, and the forehead mirror. The next day the vision was as before; and there moderate reaction from the operation had taken place.

On the subsequent day the sight was reduced to the ability to counting fingers at ten feet ($=\frac{1}{100}$ nearly): the result of a hemorrhage from the iris. In two or three days this was nearly absorbed, when another hemorrhage occurred, somewhat smaller in quantity than the first, which, in its turn, was absorbed in about eight days. Since this period vision has gradually improved to about ⅓ (*i. e.*, from ½ previous to the iridectomy). The fellow eye counts fingers at one foot; a capsule in the lenticular fossa requiring removal to improve the vision. This case appears to be analogous to those cases of glaucoma in a single eye, where the operation seems to precipitate a glaucomatous attack in the fellow. The increase of tension in the injured eye might only have been symptomatic of a serous iritis—the result of the injury—or it might have been a true glaucomatous process. An accident of this kind is not of frequent occurrence, and is liable to overtake the surgeon if he neglect to fulfil all of the indications for treatment.

A TRAUMATIC CATARACT INDUCED BY A PENETRATING WOUND OF THE CORNEA, INFLICTED BY A GRANULE OF GUNPOWDER; ABSORPTION OF LENS AND RESTORATION OF VERY GOOD VISION.

A. B., aged 25, on the fourth of July, 1872, stooped down to fire a large-sized toy cannon, which was placed on the sidewalk. On exploding, some granules of gunpowder struck his right eye, quite filling the cornea and surrounding sclera.

I saw the patient about the second day of the injury, when the following state of things existed: Cornea and surrounding conjunctiva almost filled with grains of very coarse powder; iris attached to a cataractous lens, which was rapidly swelling; tension of eyeball not much increased; considerable pain. I at once placed the patient under ether, and proceeded to remove the granules of powder by means of a large-sized needle. About twenty granules of powder were removed from the cornea and conjunctiva. One granule more deeply embedded caused a perforation of the cornea, with obliteration of the anterior chamber, which, however, was only temporary. The retentive bandage and atropine were applied, and the pain at once lessened, until within a day or two it ceased to exist. The lens, however, swelled so as completely to fill the anterior chamber, and seemed on the point of jeopardizing the eye; but as there was very little pain, with only a moderate increase of tension, it did not seem necessary to remove lens matter, as it certainly would absorb, provided the health of the eyeball remained.

About October 1, 1872, the lens was mostly absorbed; with a cornea partly covered with punctate cicatrices. The patient counts fingers without a correcting lens, at eight feet. No further operative interference will be necessary.

There is one interesting point about this case: Where is the granule of gunpowder which penetrated the lens and produced the cataract? I infer that it is still in the region formerly occupied by the lens, and probably encapsulated in a mass of inflammatory material, unabsorbed lens matter, capsule, etc., and is, perhaps, in a state not likely to affect the eye. The rule, as is generally enough known, is, that a foreign body lodged within the eye sooner or later produces destruction of the organ by inflammation. But occasional exceptions occur, in which the foreign body has lodged in the lens and remained many years without inflicting mischief. I do not call to mind a case where a cataract has resulted from the penetrating wound, the result of a granule of gunpowder, except a single one occurring at the Manhattan Eye and Ear Hospital during the past year, the particulars of which I am unacquainted with.

The principal cause of the bad vision is the state of the cornea, the dioptric media being otherwise free from obstructions.

The optic nerve and retina are healthy.

A CASE OF TRAUMATIC CATARACT, WHERE THE LENS WAS EXTRUDED THROUGH AN OPENING IN THE CORNEA, ONE LINE IN DIAMETER, BY THE AID OF A NO. 2 BOWMAN'S PROBE, AND PRESSURE.

Mr. Hurley, aged 30, on September 1st, 1872, applied to me for an injury of the eye from a splinter which had penetrated the cornea near its superior portion, entered the lens, and produced a cataract.

There was little pain, and the usual treatment was instituted for about one week, when, the anterior chamber becoming filled with lens matter, the ciliary injection become more aggravated and the tension of the eyeball, which before was nearly normal, was now markedly increased, together with some pain; besides, the fellow eye was growing slightly irritable, with a disinclination to use the muscle of accommodation, when I determined to perform in some manner extraction of the lens. It was not convenient to use an anæsthetic; and as no assistant was by, I thought of reducing the operation to its minimum of pain and trouble. I therefore introduced Noyes' modification of Graefe's extraction knife, far enough to make a wound *one line* in diameter. Naturally enough, a little aqueous fluid escaped, but not a particle of lens matter. I then introduced a No. 2 Bowman's probe, moving the masses of lens matter towards the central stream of exit from the eye (which had been inaugurated by the separation of the lips of the wound by the probe), and by a continuation of the manœuvre, and pressure upon the eyeball by the finger, I succeeded in extracting the whole of the lens matter from the eye. It occurred to me that this operation was analogous to the procedure used in evacuating pus through a small opening by means of a probe, which is sometimes done when objections exist to free incisions.

The reaction from this operation was very moderate, there being no pain; and within two or three days a subsidence of the circum-corneal injection resulted. There is still a capsule in the lenticular fossa, requiring an operation.

The use of the probe in this manner was suggested by the directions given by Sodburg Wells in paracentesis of the cornea; which is to introduce a probe and thereby separate the lips of the wound to facilitate discharge of aqueous fluid.

It might be urged that a probe introduced into the eye added to the irritation more than the smallness of the corneal wound detracted from it; it is possible this may be so, although a probe passed into the anterior chamber of the eye is comparatively harmless.

Since writing the above the patient has returned, and now (Nov. 1st, 1872), after about two months, the capsule has been so far absorbed as to permit of $\frac{1}{10}$ vision, with a central movable pupil. I have no doubt but that vision will become normal without further operation.

Progress of Medical Science.

CARBOLIC ACID AND THE CARBOLATES IN PRURIGO AND PRURITUS.—In the treatment of these most obstinate affections, Von Rothmund, of Munich, believes carbolic acid to be the most efficient remedy. He recommends the internal use of about four grains a day in divided doses. If, however, the odor be objectionable, he would substitute the carbolate of soda. He has also had great success from hypodermic injections at the seat of irritation. In these cases more benefit seems to be derived from weak solutions of pure carbolic acid than from the carbolates. The formula he employs is:—

℞ Acidi carboli., gr. iv—vj.
Aquæ destillat., ℥ i.
M.

He has never observed pain following this latter method of treatment, nor has there been any subsequent inflammatory action.—*Bayer, Int. Blatt*, 1872.

TREATMENT OF DIPHTHERIA.—Dr. Goering, of Sobernheim, relates a case of diphtheria which was unrelieved by cauterizations, emetics, and vesicants, but showed marked improvement after the inhalation of bromine and bromide of potash. He employed these two remedies in the strength of one part each to one hundred and fifty parts of water. He further painted the throat occasionally with the same solution, and gave bromide of potash internally. At first the inhalations were repeated every half hour, though they seemed to produce suffocative attacks. In a few hours, however, the distressing dyspnœa was permanently relieved, and the patient subsequently made a rapid recovery.—*Memorabilien*, 10, 1872.

TREATMENT OF UMBILICAL HERNIA.—A novel method for the relief of strangulated umbilical hernia is described by Froumüller in his Notes of Hospital Practice. A patient who was under treatment for some lung disorder, took an active purgative. The medicine acted violently, and during the act of defecation an old umbilical hernia came down. Shortly after, nausea, vomiting, and enteritis set in. As he was extremely unwilling to allow any attempts towards reposition to be made on the part of his attending surgeon, he begged permission to try a plan of his own; leave was given him, and he succeeded admirably by the following procedure: Taking an ordinary cupping-glass of pretty large size, he exhausted the air and then applied it over the umbilicus. The tumor immediately rose into the glass, while the strangulated intestinal loop was left free and slipped back into the abdominal cavity.—*Memorabilien*, October, 1872.

DETECTION OF ARSENIC IN ANILINE RED.—Recent examination has been made to discover the particular coloring matter used in the fabrication of the so-called fruit syrups. A case of poisoning from eating large quantities of highly-colored candies coming under the observation of the authorities at Carlsruhe, led to the investigation of the syrups used by the soda-water venders, and especial attention was given to raspberry syrup, which is most extensively used. It was found that in every case the color was due to aniline red; and as it is known that large quantities of arsenic are used in its manufacture, the usual tests for that mineral were employed, and it was found to be present in every instance.

Dr. Meyer gives the following ready method for the detection of the artificial coloring matter used, and the arsenic which it contains:

"When merely a trace of aniline is present nitric acid immediately destroys the color, while it produces no change in the color of genuine syrups. Caustic ammonia also deprives aniline of its color, while carmine is unaffected. To detect arsenic in a suspected fluid, pour a small portion into a vial, add a little muriatic acid, and then throw in a small piece of zinc that is known to contain no arsenic. Then take a narrow strip of paper, saturate it in a solution of nitrate of silver, and attach it to the bottom of the cork. If arsenic be present arseniuretted hydrogen will be evolved and the silver acid be reduced, leaving the paper blackened."—*Memorabilien*, 1872.

Removal of Both Ovaries.—Robert Battey, M.D., of Rome, Ga. (*Rich. & Louis. Med. Jour.*, October, 1872), writes to Dr. Paul F. Eve, of Nashville, Tenn., that he has been bold enough, for certain reasons, to remove both ovaries from a patient, just as she was on the eve of her menstrual crisis, and has been privileged in the opportunity of holding between his fingers, and exhibiting to others, *the living human ovary in the very act of its most vital function, ovulation.* This he believes to be unique in the annals of surgery and physiology. He has succeeded most completely in his expectation of arresting at once the menstrual violence, and thus warding off an attack, which, in his judgment, would have caused her as much suffering and peril for life as would and has the operative procedure to which he subjected her.

Puerile Incontinence of Urine.—F. A. Stanford, M.D., of Muscogee County, Ga. (*Trans. Ga. Med. Association*, 1872), mentions the case of a boy, aged 14 years, with obstinate incontinence of urine, who was relieved by the introduction of a conical steel bougie. Since treating the above case, he has had an opportunity of testing the practice in four other cases of boys from the ages of four years up to nine, with the like result. He has not yet had an opportunity of testing this course in a female, but sees no reason why it should not be equally efficacious.

Muriated Tincture of Iron as a Styptic.—Prof. W. F. Westmoreland, M.D., of Atlanta, Ga. (*Trans. Ga. Med. Association*, 1872), recommends this preparation of iron as a styptic in secondary hemorrhages, the result of some constitutional or local defect, or in the ulceration or sloughing process, as in some forms of abscess and phagedenic degeneration of tissues. Cases are related confirming his views. In addition to the prompt arrest of hemorrhage under such circumstances, there are but few better applications to the diseased or relaxed tissue, as his experience has demonstrated the fact that in the majority of such cases the application of the styptic is followed by healthy granulations.

Purulent Aural Catarrh.—George C. Harlan, M.D., Surgeon to Wills Ophthalmic Hospital, Philadelphia (*Philadelphia Med. Times*, Nov. 16, 1872), relates a fatal case of purulent aural catarrh, occurring in a strumous girl, 22 years old, who had been subject since early childhood to occasional attacks of pain in the left ear, with slight discharge. The points of interest in the case were as follows: 1. It adds one more to the many recorded warnings against neglecting "a slight discharge from the ear." 2. The subject has an important bearing upon life insurance; and some English companies decline to consider the case of an applicant who has a chronic discharge from the ear. 3. The ophthalmoscopic examination affords an illustration of the great value of this means of diagnosis in cerebral disease. It is not yet so general, in this country at least, as it should be.

Hæmatoma of the Ear.—William Keller, M.D., Philadelphia (*Philadelphia Med. Times*, Nov. 16, 1872), in giving an explanation of the origin of hæmatoma of the ear (hæmatoma auriculæ, othæmatoma of authors), a tumor which grows from the inner side of the concha auriculæ, fluctuating to the touch, and containing fluid blood—relates the theory of Brown-Séquard, given in his recent lecture on diseases of the brain. According to this physiologist, the extravasation of the blood in the concha of the ear is caused by a lesion of the left posterior part of the brain, which may be produced in animals artificially by attacking this part of the organ. He thinks this will explain, in a reasonable and conclusive manner, a symptom whose real cause is so little known.

Vaginal Dilator.—Dr. Cutter, of Boston, Mass. (*Jour. Gynæcological Society*, Oct., 1872), at a recent meeting of the Gynæcological Society of Boston, exhibited a new form of vaginal dilator, which he had first employed in the following case, to which he had been called by Dr. Harlow, of Woburn: It was one of complete atresia vaginæ in a girl of fourteen. Five years before she had had an attack of diphtheria, and from this he was inclined to suppose the present disease had originated, by the false membrane becoming organized. Dr. Harlow had forced a small opening with a pocket-probe, with the discharge, of fetid pus. Fearing to occasion septicæmia, he did no more at the time, but applied to Dr. Cutter for a dilator. He was advised to use the one exhibited, which had been contrived for the larnyx. It was found to answer well. Washes of carbolic acid were employed, and the menses subsequently appeared for the first time.

Double Vagina and Uterus.—D. M. Edgerly, M.D., of West Newton, Mass. (*Bost. Med. and Surg. Jour.*), publishes a case of double vagina and uterus, occurring in an Irishwoman, 35 years of age, who had been delivered of her first child. On the right side he found a vagina of ordinary size, and a uterus rather larger than normal, involution not being yet completed. On the left side was a small vagina, not large enough to admit a medium-sized glass speculum, also the cervix of a rudimentary uterus; the body of the second uterus could be felt resting on the cervix of the one which had been impregnated.

Early Menstruation.—At a meeting of the Middlesex, East District, Medical Society, held at Lexington, Mass., Dr. Holmes (*Bost. Med. and Surg. Jour.*), mentioned the recent case of a birth of a child, in whom the "show" commenced on the fifth day after birth, continuing at the rate of two teaspoonfuls per day for two days, ceasing on the third. There were no abnormal appearances about the vulva or other parts of the child. Dr. Jordan, of South Reading, reported a similar case. Dr. Chapin reported the existence of a case of persistent menstruation at the age of one year.

Dysphonia and Aphonia.—Thos. F. Rumbold, M.D., of St. Louis, Mo. (*Med. Archives, October*, 1872), publishes eleven cases of these affections, with improvement, in the majority of them, after a systematic application of sprays thrown into the naso-pharyngeal space in connection with the induction current applied daily to the vocal cords by the Mackenzie throat-electrode. In the case of a lawyer, aged 43 years, with extreme hardness (occasioned by the utmost straining of the voice, while engaged in an exciting fox-hunt), attended with hyperæmia of the vocal cords, the pharynx and larynx were sprayed with about a drachm of the following mixture, recommended by Dr. O. F. Potter, of St. Louis: ℞ Tinct. muriate of iron, muriatic acid, āā f ʒ ij.; chlorate of potassa, ʒ ij.; simple syrup, water, āā ℥ ij. Only two applications were made, which completed the treatment, the voice soon returning; all appearance of hyperæmia having disappeared from the vocal cords.

The induction current in these cases was applied externally—the negative pole on the back of the neck, the positive on the vocal cords or on the pomum Adami. The strength of each application was always graduated according to the sensibility of the part

treated, always causing contraction of the muscles, but never producing much pain.

Replacement and Reunion of Portion of a Finger.—Edward L. H. Barry, M.D., Jerseyville, Ill. (*Med. Archives*, October, 1872), reports a case of reunion of a portion of a finger, which had been replaced a half-hour after its accidental amputation. The patient accidentally amputated a portion of the index finger of the left hand. The line of amputation was from a point an inch and a half from the end of the finger on its inner or proximate side, involving the joint. The piece of finger was finally found half an hour after the accident amongst some chips near the wood-block upon which he had separated it. Although this time had elapsed, an effort was made to secure reunion of the amputated part. It was thoroughly warmed by placing it in a bowl of moderately hot water, and having carefully cleansed the stump, he placed the parts in accurate apposition, and secured them thus by adhesive strips and careful bandaging, and then enveloped the whole hand in warm flannel, with directions to sustain the temperature by constant warmth, which was effected by placing his bed near the stove, and his hand on a piece of wood in the oven, the temperature of which, for two days and nights, was carefully regulated by an attendant.

On the fourth day suppuration commenced, when warm poultices were applied and continued for four weeks, using as a wash a weak solution of carbolic acid before applying the poultices. Not an unfavorable symptom presented. With the process of healing, sensibility was gradually restored; and in about two months from the occurrence of the accident there was complete reunion.

At the date of publication, the patient informed him that sensation in the part was perfect, but there was no voluntary motion. He could move the joint, however, by using the fingers of the other hand, but could not bend it otherwise.

Rheumatic Iritis with Polycoria.—F. D. Cunningham, M.D., of Richmond, Va. (*Virg. Clin. Record*, July, 1872), mentions an unusual case of this particular form of anomaly; he does not find a similar case recorded in the annual reports of several of the ophthalmic institutions. The patient, a colored male, was 26 years old, and presented a congenital anomaly in the form of a double pupil of the right eye.

Foreign Bodies in the Œsophagus.—Dr. Guersant, in a series of papers "On Surgical Diseases of Infants," etc., now being published in *The Medical News and Library*, lays down the following treatment for the extraction of foreign bodies in the œsophagus: There are cases in which extraction can be made by means of polypus, or cranesbill forceps. As a general thing, these means are very useful in extracting bones in the pharynx or in the upper part of the œsophagus. Generally, after having explored at first with the eyes, then with the finger or with the œsophageal sound, the indication is to perform certain extractions with the œsophageal forceps. When the foreign body is appreciable to the touch in the cervical region, the surgeon should hold the portion of the neck in which the substance is felt with the fingers of the left hand, which support it and prevent it thus from being pushed forwards with the forceps, which is directed with the right hand. When a hook has been swallowed, the extraction should be made thus: A steel ball is pierced at its centre, through which the thread is passed which holds the hook, and the ball is made to slide over the thread; then using a reed, the knots of which are perforated, this last is conducted by means of the thread as far as the ball. By drawing gently on the reed, the hook may be detached, and in drawing on the thread the ball, hook, and the reed may come up. The double-ring hook of Graefe is very effective, and has done good service to Dupuytren, Blondin, Bérard, and others, chiefly for the removal of pieces of money. A sponge fastened on a whalebone, which may be introduced without being moistened between the walls of the œsophagus and the foreign body, is very useful. The sponge is left several minutes beneath the foreign body to be extracted; it thus increases in volume, and when withdrawn the foreign body is brought away with it. When those various means of extraction fail, methods of pushing the foreign body into the stomach should be resorted to. As a last resort, perform œsophagotomy or tracheotomy.

Dislocation of the Ulna.—A case of dislocation of the lower end of the ulna forwards is reported by John H. Gilman, M.D., Harv., Lowell, Mass. (*Boston Medical and Surgical Journal*, October 31, 1872). It occurred while the patient was engaged in fixing a loom in the boot-mill of that city. The left forearm, being between the spokes of a wheel when the loom was set in motion, was violently turned outwards. On examination, the hand was found in a state of fixed supination; on looking at the back of the wrist, there was a marked depression of the ulnar portion, and an unusual prominence of the corresponding portion on the frontal aspect of the wrist. Reduction was effected by grasping the hand and making extension (counter-extension being made at the elbow), slightly pronating the hand and raising the bone into place with the right hand.

Reading Medical Works by Non-Professional People Dangerous.—Dr. Fordyce Barker, of New York (*N. Y. Med. Jour.*, Nov., 1872), in his paper on "Puerperal Mania," mentions, in speaking of *exciting causes*, a curious fact that had occurred in his experience. Since 1855 he has seen thirteen cases of puerperal mania in the wives of physicians, nine in New York city, and four in the adjoining cities. All but one were primiparæ. It seemed very extraordinary to him that so large a number should have occurred in one special class, and he thinks this is the probable explanation: All of these were ladies of education and more than usual quickness of intellect; and, beginning a new experience in life, and having access to their husbands' books, they had probably read just enough on midwifery to fill their minds with apprehensions as to the horrors which might be in store for them, and thus developed the cerebral disturbances, just as any other moral emotions may.

Puncture of the Bladder.—Dr. James L. Little, of New York (*N. Y. Med. Jour.*, Nov. 1872), records a case of puncture of the bladder by Dieulafoy's aspirator, with a description of the instrument. He suggests that, in using this instrument for puncture of the bladder, the following rules should be observed: 1st. The patient should lie on his back, and, if the bladder is not much distended, the operation will be facilitated by slightly elevating the patient's hips by means of a pillow placed beneath them. 2d. The punctures should be made on or near the median line, from one inch to one inch and a half above the pubes, and should be made each time in a different place. In the case described, the punctures were about a line apart, and extended over an area about half an inch in diam-

cter. Mr. Watchet recommends the No. 2 capillary trocar; but in cases where cystitis exists, and the urine is loaded with pus, mucus, or the phosphates, one of the larger trocars may be used with safety. 3d. The bladder may, when necessary, be washed out, by filling the cylinder with water from the basin, and reversing the action of the instrument, without withdrawing the trocar from the bladder.

Lime for Poisoning by Plants and Insects.—According to the *Boston Journal of Chemistry*, a standing antidote for poison by oak, ivy, etc., is to take a handful of quick-lime, dissolve in water, let it stand half an hour, then paint the poisoned parts with it. Three or four applications cure the most aggravated cases. Poison from bees, hornets, spider-bites, etc., is instantly arrested by the application of equal parts of common salt and bicarbonate of soda, well rubbed in on the place bitten or stung.

Bronchocele.—Dr. Fenwick, of Montreal (*Canada Medical Record*), read a lengthy paper on "Bronchocele," at the last meeting of the Medico Chirurgical Society of Montreal, and then detailed the case of a healthy girl aged twenty-one years, with an enormous fibro-cystic tumor of the neck, consisting of four lobes, two large lobes on the left side, one in the centre or isthmus, and one very large lobe on the right side, measuring seventeen inches in circumference; there was much pulsation through the mass, the veins being very large, and the whole was raised by the larynx in the act of swallowing. The whole was successfully removed, after the plan recommended by Prof. Green, of Portland, Maine. There was fearful hemorrhage, but the results of the operation were very satisfactory.

Nursing Sore Mouth.—In answer to a communication of Aug. Rhoads, M.D., of Papinville, Missouri, on this subject, Dr. N. S. Davis, of Chicago, Illinois (*Medical Examiner*), regards the affection as arising essentially from a deficiency of phosphatic salts in the blood. The woman, in furnishing from the blood the material necessary for the nutrition and growth of herself and child, does not assimilate these salts fast enough to supply the demand. The indication for treatment is chiefly to supply this deficiency; and no *tonics*, merely as such, which do not contain these salts as prominent constituents, will do any permanent good. As soon as the patient begins to feel the scalding and tender sensations in the edges of the tongue and mouth, she should be required to take regularly a fluid drachm of the compound syrup of the hypophosphites at each meal-time. In many instances it will be found necessary to keep up the supply of medicine during the whole period of nursing.

There are other prescriptions which will answer a similar purpose. One of the best is the mixture of extract of malt two parts, and compound syrup of hypophosphites one part, given in doses of a small tablespoonful at each meal. If the disease is neglected, or treated with ordinary tonics or stimulants, or both, until the mucous membrane of the mouth, fauces, stomach, etc., is already extensively ulcerated, and the blood of the patient extremely impoverished, no treatment may supersede the necessity for weaning the child.

Agoraphobia.—S. G. Webber, M.D., Harv. (*Boston Medical and Surgical Journal*), contributes a case of agoraphobia, having a partial resemblance of symptoms between it and the cases related by Prof. C. Westphal in the *Archiv für Psychiatrie und Nervenkrankheiten*, III., 1. He also alludes to a case reported in the *Cin. Clinic*, vol. 2d, No. 6, 1872. The peculiar symptom that the patient described, inability to cross a street, has led Dr. Westphal to give the name *agoraphobia* to the affection. The latter thinks it is clearly of cerebral origin, not epileptic nor epileptoid; has as little analogy with normal psychological phenomena, and is as little to be explained by them as other pathological conditions of the feelings, affections, ideas, and impulses. He does not undertake to settle the nature of the affection or symptom, or to decide as to the peculiar lesion giving rise to it, but recommends the careful analysis of such phenomena, in order to arrive at a decision as to their nature and cause.

Sudden Death in Puerperal Cases.—S. L. Jepson, M.D., of Wheeling, W. Va. (*Am. Jour. Obstetrics*), has an extended paper on "Sudden Death in Puerperal Cases," in which he accounts as causes for a very large proportion of sudden deaths that occur during or soon after parturition, the following: syncope; shock; embolism; pre-existing heart disease; hemorrhage; and entrance of air into uterine sinuses. Of the minor causes and conditions there are: pulmonary œdema; degenerative lesion of the kidneys; valvular heart disease, with dilatation; anæmia, with dilatation of the heart; general œdema of pregnancy. Rupture of a varicocele of the ovarian vein, rupture of a hepatic abscess during labor, peritoneal fissures on the uterus, rupture of a large aneurism, severe hæmoptysis or hæmatemesis during the violent throes of the second stage of labor, laceration of the right ventricle of the heart, are given by various writers as causes.

In closing, the following rules are appended in the *treatment of cases in which air has entered the veins:* 1st. Remove clots or other obstruction at the mouth of the womb which may prevent the free exit of any pent-up air. Resort to pressure, or any other proper means that may be necessary to bring about a firm contraction of the uterus. 2d. Resort to artificial respiration, which, by keeping up the action of the heart, may lead to the propulsion of the spumous blood through the capillaries. Electrization of the phrenic nerve has also been used. 3d. Always keep the patient in the recumbent position, which promotes the flow of arterial blood to the brain. Pressure upon the abdominal aorta, or iliacs, and upon the axillary arteries, has also been recommended for this purpose. 4th. Opening the right jugular vein is also recommended by surgical writers, in the hope of directly relieving the right side of the heart of an excess of venous blood. 5th. In addition to these means, brandy, diffusible stimulants, and all the remedies usually administered in syncope, are generally appropriate.

Preventive Measures.—Deliver the patient on her back. Give a good dose of ergot as soon as the child is born. Practise Crede's method in removing the placenta. Compress the uterus after the expulsion of the placenta, as directed, until the bandage is applied. Allow no clots to collect in the uterus. Direct the patient to keep the thighs approximated.

Excision of the Hip-Joint.—D. D. Bramble, M.D., Prof. Surgery in Cin. Col. Medicine and Surgery (*Cin. Med. News*, Oct. 1872), recently performed, with good result, the operation of excision of the hip-joint, on a male aged 21, with femoral coxalgia of five years' standing. Three inches of the bone, with nearly the whole of the acetabulum, were removed.

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, March 1, 1873.

QUARANTINE ON THE SOUTHERN AND GULF COASTS.

Assistant Surgeon Harvey E. Brown, U. S. Army, has transmitted a report to Congress by the Secretary of War in compliance with the joint resolution, approved June 6, 1872, providing for a more efficient system of quarantine on the Southern and Gulf coasts. To all interested in State medicine or sanitary reform this report will be welcomed as supplying a desideratum; for the subject of quarantine is not a beaten track. A practical acquaintance with the complications and difficulties which render the present system of quarantines in many cases inefficient and impracticable, and the failure to find, after a prolonged search in numerous standard medical works and cyclopedias, English, French, and German, any definite information on the subject, satisfies the latter assertion. Even in Appleton's Cyclopedia, which claims to have articles on all subjects, the word quarantine does not occur, and in various commercial dictionaries the subject is disposed of in a few paragraphs. Mentioning the meagre literature of this subject to a military friend, some time since, he remarked, "Perhaps the subject is not considered worth writing about." However that may be, Dr. Brown, after a careful examination of facts, and as a result of his inspections, begins a very readable report by enunciating the following propositions:—

1st. That in the vast majority of epidemics, if not all, that have occurred in the United States, the germinal principle of the disease was imported from elsewhere, and was not due to local causes.

2d. That a system of quarantine can be organized which will prove effective in preventing invasions of yellow fever.

3d. That a properly organized system, so far from interfering with the interests of commerce, will prove really beneficial to the commercial prosperity of ports where established.

4th. That the present quarantines at the South, being established by either State or municipal authority, lack that uniformity which is absolutely necessary to their efficiency, are not founded on rational views of the pathology of the disease, and are generally defective in their administration, and that, consequently, a system of a different character must be adopted to attain the end desired.

5th. That yellow fever needs to be planted in a favorable soil in order to become epidemic, and that, consequently, the danger from the disease is measurably lessened in proportion as attention is paid to the local hygienic and sanitary condition of those parts of the ports or towns which, by reason of the character of the inhabitants or other causes, are usually the habitations of the earlier cases.

Without attempting to criticise these conclusions (which surely cannot claim the charm of novelty), it may be remarked with regard to the origin, the geographical march, the nature, and prophylaxis of yellow fever, that no great question of medicine and of hygiene presents by the side of well-defined certainties so many mysteries and contradictions. The relations of this malady with the combined conditions, climatic, geologic, and economic, have been the subject of numerous and persevering researches, which have only furnished doubtful and contradictory results. In an historical sketch of yellow fever Dr. Brown alludes to its eastern origin, and to the prevalence of epidemical fevers of a malignant type at Darien in 1514. In relating these facts Dr. Brown might have mentioned the earlier occurrence of yellow fever; for history informs us with certainty, that between the years 1333 and the period of the discovery of America, that disease had prevailed epidemically twenty-two times at Barcelona.*

Having little temptation to dwell on these scanty and vague archæological researches, we pass them by to arrive the quicker at the discussion of the introduction of the yellow fever into the various ports of the Atlantic and Gulf coasts. The facts here adduced incline to the side of the extra mineral source of infection. Although bitter controversies have arisen as to the local or foreign origin of yellow fever, and very able articles have been written on both sides of the question, a good case is made out. Whatever may have been the reporter's predilections, the testimony seems to be taken fairly and impartially, and is concurrently arranged. Noticeable is the insanitary condition of the towns where the yellow fever prevailed, and the great similarity of meteorological conditions observed in the Texas towns during the prevalence of this epidemic. The town of Sabine (Texas) is thus described:—"Probably Sabine will carry away the palm for being the filthiest hole in the United States. Used

* Second Representation to the Spanish Cortes. Madrid, 1822.

chiefly as a cattle-port for shipping the beeves of Eastern Texas to New Orleans, the street bordering on the river and in the vicinity of the wharf was almost ankle deep in cow manure, and never cleaned, while the houses in the vicinity are old, rickety, and the yards filled with pools of stagnant water, filthy sinks, and everything that could contaminate the air."

After a brief allusion to epidemics in foreign countries, Dr. Brown leaves the domain of ascertained facts and views his subject in another aspect,—"the mode of existence of contagious matter." He mentions the generally accepted theories of different authors, which he handles with modesty; but he has not elucidated the question, and the nature of the yellow fever poison still remains a lugubrious mystery. We are informed that the facts are indisputable as to the development of yellow fever in the filthy holds of ships, and that among the personal conditions favoring pestilential propagation, psychical depression operates more powerfully than any other predisposing cause in affording a congenial resting-place for the germs of the disease. Perhaps the personal observation of most medical men who have witnessed epidemics will confirm the truth of the latter observation, as well as the fact that the best individual hygiene during such times is calmness and serenity of mind,—moral force here being of equal importance with physical health. On the question of the effectiveness of quarantine in preventing invasions of yellow fever, we find an unqualified answer in favor of quarantine. The discussion on this point is broad; among other things the writer says:—"The *point d'appui* of the quarantine of the future is to be the disinfection of the ship and her cargo and the care of the sick, and the well will be subjected to detention only so long as to insure their safety and avoid the possibility of their infecting the place of their destination." Next follows a brief abstract of the quarantine laws now in operation in the various States. Concerning the squabbles among the quarantine authorities, and the absurdities of these laws and their defective administration, the following remark occurs:—"It needs but a glance at the foregoing abstracts to be convinced how impossible it is to maintain an effective system of quarantine based on such heterogeneous enactments." In reply to the last inquiry of the joint resolution, "What system will least interfere with the interests of commerce at said ports?" the tenor of the report is strongly in favor of the adoption and control of quarantine by the General Government; and the adoption of precautionary measures at the port of departure and the perfecting of international arrangements with friendly powers is recommended. There is one remark on the necessity of quarantine being under the control of the Government that we cannot refrain from quoting:—"If the meteorological phenomena upon which storms depend and their effect upon commerce are deemed of sufficient importance to merit the attention of a government, how much more so are the phases of a disease which renders a large portion of the coast of the United States uninhabitable during several months, which in its periodical visitations sacrifices thousands of lives, paralyzes trade, diminishes immigration, and retards the progress of some of the most important cities on the continent?" An additional reason, we are told, why action should be taken by the General Government with a view to an international quarantine is the necessity for a vigilant quarantine at the mouth of the Rio Grande, which it is at present impossible to establish, on account of the extreme aversion of the local and State authorities at Matamoros to all quarantine measures.

Throughout the report a central idea seems to have been kept in view; but the remarks as to the War Department being the safest and best director of quarantine affairs, and the weather reports affording presumptive evidence of the fidelity of the Medical Department, although prudent and judicious, will be regarded by many as entirely gratuitous.

Concluding what we have to say, and taking a general view of the whole subject of quarantine, it is manifest that the present system is not one that can be enforced with adequate security to the public service, and without unnecessary severity upon individuals, and that the administration of quarantine at the port of arrival is comparatively useless, so long as the provisions desirable at the port of embarkation and the sanitary means to be enforced during the voyage are neglected. Only by a cosmopolitan code of regulations can a proper quarantine be enforced; the question is perhaps one of the most serious difficulties of sanitary police and of international hygiene. We have had a Geneva Arbitration, why cannot diplomacy be brought into effective operation in quarantine affairs? No legislator will hesitate to admit that the best government is one that brings the greatest good to the greatest number, and no physician will acknowledge that cure is better than prevention. Comparing the relative merits of these two branches of medical knowledge with the first proposition, the inference is obvious. It is to be hoped, that the moral aid of public opinion and the material assistance of science may be the means of inducing the National Legislature to adopt some comprehensive measure, by which the confused mass of sanitary laws of the different States may be arranged and codified, the good offices of international arrangement secured, and ample opportunities afforded workers in a direction where the greatest triumphs of medical science are to be achieved.

THE MEDICAL RECORD'S NAMESAKE.

SINCE our editorial of last month, relative to the cool plagiarism of the name of this Journal by an English periodical recently begun, we have seen three numbers of said periodical, and find that not only our name, but the size and shape of page, column, and

ype, have been copied as nearly as possible by our *honorable* cousins, who have been so fond of reminding us of American shortcomings of this character heretofore. With considerable curiosity, but in vain, we have searched the three numbers referred to in hope of finding some allusion to ourselves, partly that we might learn what our own name was to be in the future. Perhaps, in our American ignorance, we have not known that our real name was "The New York Medical Record," or "The American Medical Record," or some other kind of Medical Record, and not *simply* "The Medical Record." We cannot believe, however, that the large number of eminent gentlemen whose names are printed as collaborators will countenance the discourteous plagiarism of which Mr. Earnest Hart and his publishers, Smith, Elder & Co., have been guilty, and we desire to call their attention to the subject.

THE ALTERATION OF PRESCRIPTIONS.

In another part of the Record is a communication bearing upon the subject of alteration of physicians' prescriptions by pharmacists. It will be recollected that some time ago we took occasion to ventilate the subject somewhat, founding our remarks upon some statements made in a communication by Prof. Barker of this city. The College of Pharmacy has deemed the subject of such importance, that it has taken pains to investigate the matter, and has given us the report of its committee. We are glad of the opportunity of setting the College right in the matter, and of commending its determination of punishing any convicted offenders against its Code of Ethics. The latter, in our opinion, embodies in its provisions everything calculated to entitle the institution in question to the unqualified confidence and respect of the medical profession.

Reviews and Notices of Books.

Transactions of the American Medical Association. 1872. Vol. 23.

This volume contains both good and evil. The prize essay of Dr. Percy, on *Phosphorus;* the papers of Dr. Muzzy, on *Electrolysis in Cancer;* of Dr. Richardson, of Dr. Seguin, of Dr. Knapp on *Recent Advances in the Operation for Cataract;* and the address of President Yandell, and some of the reports of committees, and other papers also, are worthy of preservation in a permanent form, and ought to be published in some widely-circulated medical journal. But between these really valuable papers is sandwiched a vast amount of trash.

The reports on the climatology of the different States are miracles of dilution. Ideas and facts that ought to be compressed in a few pages are expanded and attenuated until they become as thin as a comet's tail. And yet there is much in these reports of genuine worth; but it is so buried under mountains of words and figures that it will be lost to science and humanity.

We would make this suggestion to the managers of the American Medical Association:

First. Let the transactions be confined to the reports of committees, abridged by the committee of publication, the lists of members, minutes of the meetings, and other miscellaneous matter. A volume thus constituted would be small and compact, and valuable for reference.

Secondly. Let the papers read in the sections—if they have any value—be recommended for publication in some medical journal. Such a recommendation would be an indorsement, and would give the papers so recommended a dignity and prestige. Under the present custom, papers of decided value, as in the present volume, are but little more read than if they were shut up in one of the vaults of Greenwood.

Injuries of Nerves and their Consequences. By S. Weir Mitchell, M.D., etc. Philadelphia. 1872. pp. 377.

Those who have studied Dr. Mitchell's earlier contributions to the surgical pathology of nerves must feel grateful for the summing up of his vast experience, and for the re-statement of his opinions constituting the volume to which we desire to call attention.

The first four chapters of the book treat of general considerations touching the anatomy, normal and pathological physiology of nerves. In the chapter upon anatomy, we were somewhat surprised to find no mention of Van der Kolk's law of distribution of the sensitive and motor filaments of one nerve trunk—a law which affords great aid in the diagnosis of the seat of nerve lesions. Under the head of neuro-physiology, Dr. M. gives much space to the question of trophic nerves, and while apparently not believing Samuel's assertion of the existence of such nerves, does not frankly deny its truth. He points out the circumstances under which real alterations of nutrition (beyond mere atrophy) take place, and holds to an opinion formerly expressed by himself, that the lesion in such cases is an irritative one, and not a simple severance of nerve fibres. He does not believe that lesions of the vaso-motor system give rise to alterations of nutrition. Neither is Dr. Mitchell willing to admit that there are separate conductors for the various modes of sensibility—contact, pain, temperature, etc. While speaking of continued activity of nerves in the midst of considerable organic change in their sheaths and myeline, our author inclines to the opinion that the axis cylinder is the essential part of nerve fibres; a view certainly sustained by phenomena observed in disseminated and columnar sclerosis of the nervous centres. In the fourth chapter are tolerably full accounts of congestion of nerves (experimentally studied), acute and chronic neuritis. The fact is stated that chronic neuritis tends to advance centripetally along nerve trunks; and it is further observed, that in this disease the secondary atrophy of nerve fibres is never complete, healthy fibres being met with in nerves which to the naked eye resemble tendons. For the treatment of congested or inflamed nerves, Dr. M. recommends ice in bladders, rest, counter-irritants (secondary faradic current), and such sedatives as morphia and atropia, used hypodermically. The chapter ends with a good account of the Wallerian degeneration, and of the regeneration of nerves. A misprint makes Waller's researches date 1862, whereas the correct time of publication is 1852.

In Chapter V. incised, punctured, contused, and lacerated wounds of nerves are spoken of in detail and illustrated by cases. Dr. M. almost despairs of obtaining union in the simplest cases of division of nerves in man. Compression of nerves receives more attention, and some ingenious experiments of the author add interest to the section. In these it was found that nerve trunks (in rabbits) would bear twenty inches of mercury before losing their physiological properties; which fact, taken with the other, that an extreme weight (108–116 lbs.) is required to break the sciatic nerve in the human cadaver (p. 22), illustrates the wonderful power of resistance possessed by nerve trunks. Chapter VI. treats of the symptoms which immediately follow injuries of nerves, such as local sensations, shock, distant reflex loss of function; and Chapter VII. of the remote symptoms, tetanus and chorea being disposed of with little more than a mention, while trophic changes in parts supplied by the affected nerves—atrophy, cutaneous eruptions, glossy skin, loss of hair, alterations in the connective tissue, in joints, changes in temperature—are most thoroughly and ably detailed. Chapter VIII. is devoted in greater part to the study of various alterations of sensibility, a great deal of space being taken up with an account of the burning pain so characteristic of irritative nerve lesion, and called *causalgia* by Dr. Mitchell. A vivid portrait of the sufferer from causalgia is presented on pp. 197–8, a description the accuracy of which is corroborated by our own experience. Paralysis and spasm, consequent upon lesion of motor nerves, form the subject of interesting paragraphs. In Chapter IX., Dr. M., speaking of diagnosis and prognosis in nerve injuries, records his doubt as to our ability to diagnose the nature of the injury from the symptoms. Diagnosis between peripheral and spinal cord lesions is rightly insisted on, and Stich's plan of testing reflex action is adopted. It is but justice to state that, three years before Stich, Dr. Brown-Séquard* pointed out the value of this means. As regards prognosis, Dr. Mitchell is not sanguine of obtaining a cure after nerve section or laceration; but he adds that in the worst cases remarkable improvement occurs in the course of two or more years. Chapters X., XI., and XII. give details concerning treatment. Among the means which tend to cure muscular atrophy and paralysis, we have faradic electricity recommended as the best, together with exercise, shampooing, etc. For the relief of anæsthesia nothing has appeared so efficacious to the author as the use of the wire brush connected with the secondary faradic current, and applied to the dried skin. For the diminution of neuralgia (causalgia in particular) a variety of agents are well spoken of: counter-irritants (as extensively applied as possible), cold applications, the hypodermic use of morphia and atropia, and lastly resection of nerves above the seat of injury. This operation has often afforded relief, and occasionally has brought about a complete cure. The concluding chapters treat of wounds of special nerves (sympathetic and cranial), and of neural maladies of stumps.

This most original volume cannot but prove a storehouse of facts which can be utilized by the surgeon and the physiologist. The scientific temper of the work, the masterly descriptions of cases and of symptoms, the moderation in drawing conclusions, and the erudition exhibited, are all worthy of Dr. Mitchell's exalted reputation. We cannot close without expressing the hope that the author will be able at some future time to give us the results of his experience and researches in the more obscure field of central neural pathology.

* Brown-Séquard, "Experimental Researches applied to Physiology and Pathology." New York, 1853. p. 73.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, January 16th, 1873.

DR. AUSTIN FLINT, PRESIDENT, in the Chair.

ADDRESS OF RETIRING PRESIDENT.

DR. E. R. PEASLEE, the retiring President, made the following remarks:

Fellows of the New York Academy of Medicine: The moment has now arrived which relieves me of the office which your generosity gave to me two years ago, but nothing will ever deprive me of a full appreciation, and a grateful recollection of the honor thus conferred.

I entered upon my official duties with misgivings, being aware that I have no special talent in that direction. I have performed them according to my ability in the midst of other pressing duties, and not seldom—as any one else would—to the neglect of the latter; and I now relinquish them with a two-fold pleasure. In the first place, I need the time for other pressing demands; and in the second, I have the great satisfaction of seeing next in this chair, one whom I have long recognized as a friend, and who will, I know, perform its duties both efficiently and conscientiously.

I know you will extend to him the same generous support which you have accorded to me. It must always be the fact in an organization like this, that the scientific labor is performed by a comparatively small number of the members—much smaller indeed than should be the case. I have aimed to bring new laborers into the field, but there are still many others who, I hope, will no longer delay to take prominent parts, but will respond to the call to do so by my successor.

On the other hand, the members of the Academy may very much embarrass the presiding officer, though without any such intention; and I now speak from experience. The President must of course have a definite programme for at least three or four meetings of the Academy in advance; and though the Academy has the undoubted right to substitute or interpolate any other proceedings, as it may see fit, it may also sometimes by introducing a trivial matter to occupy the time, or by voting to adjourn fifteen minutes too soon, entirely break up the arrangements of the President, and embarrass him and those he had engaged to read papers, for several weeks afterwards.

For example: It must be admitted that the discussion of a paper should occur—unless it is thought necessary to wait for its publication—on the evening of and immediately after its reading. It is therefore to be assumed that it will not be postponed without a sufficient reason. But sometimes a member wishes to go home immediately after the reading, and looking at his time-keeper finds it is already late, *i. e.*, 9¼ or 10 o'clock, and therefore he moves that the discussion be deferred to the next meeting. There are several gentlemen present who are prepared to discuss the paper, but who will probably not be able to be present at the next

aeeting. But the Academy votes, almost as a matter f course, to adjourn, and the consequence is that few f any remarks are made on the paper at the next aeeting. As a matter of course also the same injustice s done, and the same discourtesy committed to the ıext reader, *i. e.*, the discussion is again deferred to the ollowing meeting, and under these circumstances actu-lly for want of time.

Now this may be avoided in two ways: *First*, if ny member wishes to go home after the paper has ·een read, he may quietly do so, without moving that nybody else shall also be sent home; or, *secondly*, the 'resident may be asked whether his arrangements for he next meetings will be interfered with by the post-ıonement, and if so the Academy may vote down the ıotion. In my own judgment the former course would e much the most beneficial to the Academy; since I ave observed that the person who moves the postpone-ıent of the discussion is almost sure not to manifest ny further interest in it, and sure to be absent when it oes come off. But if the motion be made it remains or the Academy to decide.

One illustration more. Your President has previously rranged for matter enough entirely to fill a particular vening to a late hour, in consequence of the intro-uction of some extra subject which could not be eferred; when some individual comes here without ny previous notification, with a patient he wishes to how to the Academy—the case being one of interest o himself at any rate, and to the Academy perhaps—erhaps not. The President cannot give him the ime without injustice to those already engaged, nd states this fact, and requests the gentleman o defer his case till the next meeting. The latter ıen appeals to the Academy, asking for a very ıort time only, since he does not wish to trouble is patient to come again; the Academy grants the rivilege; the gentleman takes such time as he pleases, nd the consequence again is that the principal paper deferred, and its reading ended so very late that ıe discussion must be put over to the next meeting. gain the discussion fails, therefore, and the whole rogramme is again disturbed for the three or four sub-quent meetings.

Of course a President will treat with courtesy and onsideration all the members of this cademy; but oth courtesy and consideration are due first of all to ıe reader of the paper for the evening; and no other ıember's claims or convenience should be allowed to onflict with his, or can do so without injustice to im. I trust, gentlemen, that you will pardon me for ıese remarks, since they do not demand an increase of ower for your presiding officer, but only such an mount of discretion as the best good of the Academy emands.

Turning to the President-elect, he further remarked: nd now, my friend, will you allow me to induct you o the chair to which you have been elected with such n unusual degree of unanimity. You need no special ıtroduction here. Your name, indeed, suggests a ature and constitution very hard and very unimpres-ble; but we know it is a misnomer in these respects, or though too rough a friction would certainly make ıe fire fly, we have always found you the highminded ıd sympathetic man, and the genial gentleman as ell as the finished scholar, the distinguished author, ıd the skilful practitioner.

The Academy has honored you by its preference. I now you, being such, will not fail to honor the Acad-ny in the chair to which you are now inducted; and present to you for your guidance the Constitution and y-laws of this Association.

INAUGURAL OF THE PRESIDENT-ELECT.

Dr. Austin Flint, Sr., in responding to the remarks of Dr. Peaslee, said, that as the future presiding officer, he should imitate his example, and hoped the action of the *flint* would not end in a *flash in the pan*. He then spoke as follows:

Fellows of the Academy of Medicine: A biennial election offers a fitting occasion for bringing before us the objects of our association, in order to see if anything can be done to give greater efficiency to the means for their accomplishment. These objects are expressed in the constitution thus: The cultivation of the Science of Medicine; the advancement of the character and honor of the profession; the elevation of the standard of medical education, and the promotion of the public health. First, and chiefly, the means for the accomplishment of these objects, are the communications, discourses, and discussions at the stated meetings of the Academy. These means constitute the important purpose for which the meetings are held. To endeavor to secure for the successive stated meetings able papers which, in addition to their intrinsic value, will be useful in calling forth profitable debate, is the most prominent of the duties pertaining to the office which I am to enter upon to night. It is obvious that success here must depend on the co-operation of the Fellows of the Academy. I shall enter upon my official duties with the belief that I may count upon this essential co-operation. I will add, I have had already abundant reason to anticipate that I shall not be disappointed in this respect.

It is well for us to keep constantly in mind the fact that the great purpose of our meetings relates to the accomplishment of the objects for which the Academy was instituted. All the time devoted to the deliberations on irrelevant matters, and on the needless or unduly prolonged considerations of questions which are trivial or of merely personal interest, is a deduction from the limited period which should be devoted to the great purpose of the meetings. This may seem to be a common-place truth; but when our conduct is to be regulated by common-place truths, they can hardly be kept too constantly before us.

I will venture a few remarks with respect to our debates. It is notorious that in almost all assemblages there are some who are over-ready to talk, and there are others who are over-reluctant to have their voices heard. The natural consequence is, the former talk too much, and the latter too little, if at all. It would be strange if the meetings of the Academy were entirely exceptional in this respect. A very simple rule of action, if strictly followed, will prevent redundancy of debate. It is to keep before the mind the inquiry, Have I anything to say which will promote the great purpose of the meetings, by the addition of facts, the citation of opinions for the elucidation, in any way, of the topics under discussion? A modification of this inquiry will render it alike a rule of conduct for those who either habitually abstain from speaking or speak too little. Can I say anything which will promote the great purpose of the meetings? Whenever any Fellow can answer this inquiry affirmatively, he is bound to speak. Keeping in view the objects of the Academy is here important. Our organization is not for polemical practice or display. The Academy is not a mental gymnasium, or a "Debating Society." Hence there should be but one motive in entering into the debates, namely, to contribute facts or opinions, and to eliminate the topics under discussion. It is hardly necessary to add, but the fact seems through modesty to be lost sight of by some of the Fellows, that the

duty, not to say privilege, of participating in debates belongs to the younger as well as the older of those who may be in attendance at the meetings. The importance of making preparation beforehand for engaging in debate is a point to be considered. To be able, without preliminary reflection or study, to do justice to a scientific or professional subject, one must be very familiar with it. In general, it may be said, that such a degree of familiarity can only be the result of the attention incident to authorship or oral teaching. With reference to this point, it seems to me desirable that, whenever practicable, ample previous notice should be given of the subject which will come up for discussion. The custom of submitting views in writing, whenever the previous notice is sufficient to admit of it, should, as it seems to me, be encouraged. They who have had personal experience in the matter, and all who have had their observations directed thereto, must be satisfied that the pen is a most useful instrument in restraining immature utterances, and also, in other ways, promoting accuracy, precision, and clearness in the enunciation of facts, opinions, and arguments.

In furtherance of the objects of the Academy, it is of course important that the meetings should be well attended. How is this to be secured? Undoubtedly neither by entreaty nor by scolding. It is certain that a large representation of the Fellows at successive meetings can never be effected by importuning them, severally or collectively, to come, or by reproaches for non-attendance. Nor would it be desirable, were it feasible, to obtain full meetings by such methods. If the meetings can be rendered sufficiently attractive by the papers which are presented and the discussions which follow, many Fellows will come; if otherwise, few will be present. Largely attended meetings, therefore, while they are highly desirable with reference to the objects of the Academy, are also evidence of the value of the work which is done for the accomplishment of these objects.

Another point may be touched upon in this connection. It is the desirableness of a punctual attendance at our meetings. Unless the meetings commence at the appointed hour, not only are some subjected to the annoyance of delay, but discussions are sometimes prevented or prematurely ended, owing to the lateness of the hour. The by-laws require that twenty-one resident Fellows shall be necessary to constitute a quorum. Not infrequently there is considerable loss of time in obtaining the registration of this number. Anticipating this, some are accustomed to come late in order to avoid waiting for the business of the evening. Let it be considered that if they who do this will come punctually, the probability is that the work could begin promptly at the appointed hour, and none would be exposed to the annoyance of waiting.

The publication of papers of interest and value has always been a feature of this Institution; and all must admit that important contributions to medical literature are contained in the printed bulletins and transactions which have emanated from the Academy. These publications, however, have had a very limited circulation beyond the Fellows of the Academy; and this has been a serious drawback in the way of their usefulness. A recent improvement consists in having but one publication, namely, the "Transactions," into which the "Bulletin" has been merged. I submit for consideration the inquiry whether it would not be a further improvement to issue the "Transactions" in a yearly volume. Among the contributions during a year, if those were to be selected for publication which were especially deserving of preservation, they would form a volume which could hardly fail soon to be in request by the members of the medical profession throughout this country and in other countries. Under these circumstances, to be ranked among the contributors to the volume would become an honor to be coveted; and herein would be an additional inducement to contribute elaborate and able articles. It is certainly a matter of reproach that the metropolis of our country is wanting in a serial of this description; and, with proper efforts, why should not the "Transactions of the New York Academy of Medicine," after some years, form a series of volumes of which the American Medical Profession would be justly proud? Why should we not in this respect emulate the Royal Medical and Chirurgical Society of London? Any one who has had occasion to consult the long series of volumes which have emanated from this Society cannot fail to appreciate the pertinency of citing its labors in this direction, as affording to us an example and encouragement. With all due respect to the Medical Periodical Press, were we successful in emulating this Society in the character of an annual volume of Transactions, it would not be the case, as it now is, that contributors of papers read at the meetings of the Academy care but little for their appearance in the printed "Transactions," preferring rather that they should be given to the medical public in the columns of a medical journal.

There is a matter of no little importance to which I should not fail to make reference. It is the possession of an appropriate building. This has been considered a desideratum from the organization of the Academy. The by-laws require, as one of the duties of the Trustees, that they take charge of the "Building Fund." A considerable sum for this fund is already acquired. No one can doubt that from the possession of an appropriate building many advantages would accrue—advantages not limited to the Fellows of the Academy, but enhancing the interests of the profession at large, both in New York and throughout the country. I shall content myself with this simple reference to the matter, the more because it will be entered into by those far more competent to enforce its claims on the attention of the Academy.

Finally, the Academy of Medicine is one of several organizations in this city for similar or kindred objects. Between these several organizations there should be maintained relations which involve only a spirit of honorable rivalry. It is a well established axiom that an individual never raises himself by efforts to depreciate a competitor; and this maxim is equally true as applied to associations. Not only are different organizations laboring for essentially the same objects, but, to a considerable extent, they embrace the same laborers for these objects. To my mind it reflects great credit upon the medical profession of this city, that these organizations are carried on actively without antagonism, each apparently being pervaded by the catholic spirit of our motto, *Una fides, altare commune.*

Thanking you for the honor which you have been pleased to confer on me, and believing that true gratitude is expressed better in actions than by words, I pledge my earnest efforts in behalf of the important objects of the Academy.

The following Resolutions moved by Dr. Wm. C. Roberts, and simultaneously seconded by Drs. Oliver White and Fordyce Barker, were unanimously passed, and ordered to be published in the medical journals.

Resolved, That the New York Academy of Medicine, in separating from their late President, Dr. E. R. Peaslee, upon the expiration of his term of office, beg to convey to him their high sense of his faithful, urbane,

and zealous services while in the chair; their warm appreciation of his great attainments as a classical and medical scholar, physiologist, pathologist and practitioner, and assure him of their affectionate regard, and best wishes for his future health and prosperity.

Resolved, That this resolution be entered on the minutes, to remain a lasting record of the sense of the Academy.

CAUSES AND TREATMENT OF ABORTION.

Dr. A. S. Church then read a paper on "The Causes, Treatment, and Prevention of Abortions," of which we give a full synopsis:

An abortion is understood to be the expulsion of the fœtus from the uterus before it has attained the degree of development necessary to render it viable. This period is usually fixed at about the end of the sixth month of pregnancy, although cases are reported where fœtuses born at the fifth month, and even at the fourth, have lived, but they are exceedingly rare, and there is usually the possibility of error in calculation. It is not uncommon for a fœtus to be born alive any time during the fourth month, and live for several hours, and occasionally a case occurs where life is prolonged until the third or fourth day, but well authenticated cases of viability occurring previous to the end of the sixth month are rare. An expulsion of the fœtus after the sixth month, and previous to the completion of the full term of gestation, is called a premature delivery.

Statistics of the frequency of abortions vary largely by different authors. Collins gives one in 66 births, Beatty 1 in 57, Churchill 1 in 26, La Chapelle 1 in 89, Deubel 1 in 12. During the last ten years to my obstetrical practice, careful notes have been kept, and I find about one miscarriage to 25 births recorded. Statistics of private practice only are reliable, as only those far advanced in pregnancy enter hospitals and lying-in asylums. Statistics also vary greatly in the different walks of life. About 4 cases occur among women who are engaged in hard work to one in a higher scale of society.

Abortions occur more frequently during the early months of pregnancy than at any subsequent time, and it may be laid down as a rule that the shorter the period of pregnancy the greater the liability to an abortion. The twentieth day after conception has taken place—that is about the time the menses would have returned, and at every subsequent period of four weeks, spontaneous abortions are particularly liable to occur, the danger growing less as pregnancy advances.

It is a popular opinion that a larger proportion of aborted embryos is of the male sex rather than female, and some authors coincide with that opinion. The difficulty of distinguishing the sex in early embryonic life, and the frequency with which the ovum is lost, render statistics unreliable; and public opinion in judging of the sex of an expelled embryo, although considerably advanced, is often in error, for in early embryonic life the clitoris and vulva are disproportionally large, and might easily be mistaken; the former for a penis, and the latter for a scrotum.

The general causes of abortion are as follows: 1st, Accidental; 2d, Constitutional; 3d, Diseases of the uterus and appendages; 4th, Abortions from habit.

In regard to *abortions from habit*, we meet with women who are in good health, who conceive readily, apparently have no uterine disease, who use all necessary care to preserve the ovum, and still have abortion after abortion occurring always about the same period of gestation. They come on without any apparent exciting cause, and are very properly termed abortions from habit. I am fully aware that this cause is not admitted by many whose opinions I highly respect, but careful observation for many years has convinced me that abortions from this cause solely are not infrequent.

An abortion occurring early in pregnancy either from habit or from causes destroying the ovum, other than violent, is not usually attended with much trouble. The ovum slips away with a few pains more or less, and without any more loss of blood than attends an ordinary menstrual flow, and with but little inconvenience to the patient.

Provoked abortions are usually very troublesome. The constitutional symptoms are prominent, the pains are hard, and continue for a day or two, sometimes for several days, the hemorrhage is profuse, often dangerous, the placenta is frequently retained, metritis, metro-peritonitis and death often follow. The explanation (independently of direct injuries to the patient), why this kind of abortion is attended with such unpleasant results, perhaps may be that the embryo, its attachments, and the uterus are in a perfectly healthy condition, and the uterus is not easily provoked to expel that which is in no way a foreign body, and as the embryo is not usually destroyed until it is expelled and the pains then cease, a portion of the placental attachment remains for some time, allowing a hemorrhage that is difficult to control.

A complete cessation of the movements of the fœtus, after they have been distinctly felt, absence of the beating of the fœtal heart, a cessation of the enlargement of the abdomen, or a diminished size, a feeling of coldness and weight in the hypogastrium, with flaccid breasts, indicate a dead fœtus, and signs of its expulsion may be encouraged.

The three important symptoms which demand consideration, are pain, hemorrhage, and an escape of the amniotic fluid.

When called to a patient that has symptoms of threatened abortion, our first duty is to decide whether the patient is really pregnant; second, whether the symptoms are those of abortion; and, if so, is an abortion inevitable? To settle the first point will sometimes require quite as much tact and shrewdness as medical skill. If the pains are without distinct remissions, and precede the hemorrhage, and are relieved by an increased flow, the cause probably is uterine congestion. If, on the contrary, the hemorrhage precedes the pains, and the pains gradually increase in severity, with distinct remissions, a miscarriage is imminent. If on making a digital examination the cervix is found to retain its normal length and thickness, and the ovum cannot be felt, and the liquor amnii has not escaped, no matter how great the hemorrhage, there is hope that an abortion may be prevented; but if the neck has become short and the os patulous, and if during the pain the membranes can be felt to be tense and protrude, the probability is that the ovum will escape in spite of efforts to prevent it.

The treatment should be preventive so long as there is a reasonable prospect of success. Nervous fears should be quieted, the patient directed to assume the recumbent posture, and such symptoms should be controlled as early as possible. Pains should be quieted by anodyne enemata, repeated as often as necessary. When the uterus shows a tendency to cast off the ovum at each pregnancy, owing to abnormal conditions within itself, it may become necessary to use an anodyne enema or suppository every night for two or three weeks, in the mean time giving attention to the general health of the patient, and the condition of the bowels. Hemorrhage should be controlled by astrin-

gents applied to the vagina or os uteri. A soft sponge saturated with alum water or tannin, squeezed nearly dry, and applied against the os, is far more effectual than astringents administered internally. Their internal administration seems to do but little good in arresting hemorrhage, and considerable harm in disturbing digestion and constipating the bowels. The only internal remedy that I have used with any satisfaction to arrest uterine hemorrhage is ergot. When the bleeding seems to come from a congested os or cervix, and is not profuse, and even slight disturbance of the placental attachment is suspected, from 10 to 20 drops of Squibb's Fl. Ext. of Ergot may be given three or four times a day with satisfactory results. If the patient is plethoric, has been accustomed to a pretty large menstrual flow, and is in the early month of pregnancy, the flow had better not be checked with astringents. A moderate bleeding from the arm will do more to preserve the ovum than anything else. The recumbent posture should not be insisted upon for more than two or three days. Confinement to the bed soon deranges the health, the appetite is lost, the patient becomes nervous, and I think is much more likely to abort than if she is allowed to be up and take moderate exercise. It is not necessary to enjoin perfect rest until hemorrhage is controlled. A patient can wear a sponge of the size of an egg medicated with alum, and be around the house without losing a drachm of blood a day, when several ounces would be lost without the use of this application. I always keep ready for use sponges soaked in a solution of alum, tannin, or acetate of lead, and then moderately compressed. I find them convenient both for vaginal and uterine application. Those intended for introduction within the os need to be more firmly compressed, smaller, and with the addition of a small quantity of gum acacia to prevent a too rapid expansion, and thereby consequent failure of introduction. Hemorrhage may be so alarming as to require not only the sponge, but a thorough tamponing of the vagina. This of course will be likely to cause the death of the ovum by a separation of the placental attachment, if the bleeding comes from the placenta, but there seems to be no choice in the matter, and there is the possibility that a clot may close the bleeding vessels, and the ovum be preserved. A tampon does not necessarily cause the destruction of the ovum.

The hemorrhage may not come from a separation of the placenta or any portion of it. It may come from an open vein just within the os or from an injury to the vagina, and in either case the tampon would be successful in arresting the hemorrhage without much risk to the ovum. We are not always sure, when called to a case of uterine hemorrhage, that a knitting needle intended to be introduced into the uterine cavity, may not have caused simply a vaginal wound, and the ovum has not been injured by either the instrument or the hemorrhage, and will not be by its arrest.

In the latter months of pregnancy, if it becomes necessary to tampon the vagina, the effect should be watched, for internal hemorrhage may take place and endanger the life of the patient. As hemorrhage is not usually very troublesome during the early months, and if it is decided that an abortion is inevitable, it had better be allowed to come unassisted, for the ovum may be expelled entire, while any assistance with the finger is pretty sure to rupture the membranes, allowing an escape of the fœtus, with a retention of the placenta, and a troublesome hemorrhage. An abortion after the third month is usually accompanied with a rupture of the membranes, after which the fœtus escapes readily enough, and the placenta is commonly retained for several days, if no assistance is rendered. If it can be hooked down with the finger and removed at once it is well to do so, but this is not always easily accomplished. If it is detached, it is advisable to make pretty persevering efforts to remove it, and if the finger fails, Dewees' blunt hook or a pair of placental forceps may be found very useful. No harm need be done with either. In some cases the placenta remains attached to the uterus, and immediately after the fœtus is expelled, the os closes so firmly as to render it impossible to introduce the finger except by a tiresome and painful process of dilatation. The hemorrhage ceases, and the uterus shows no disposition to expel its contents for several days. Under such circumstances it seems better to wait, than to use the force necessary to remove the placenta. I am well aware of the supposed danger of such a course. Hemorrhage may come on at a time when assistance is not easily obtained, and the life of the patient be jeopardized, or septicæmia may result from a putrid placenta. I have never seen harm from such delay, and think the danger considerably magnified. I have for the last two or three years, when I found it necessary or advisable to leave the placenta undelivered, introduced a carbolized sponge-tent into the os and tamponed the vagina, and on removing the tent a few hours after have succeeded with but little trouble in getting the placenta, or if I still found it attached, introduced another tent and waited a few hours longer, in the meantime giving a few doses of ergot. In removing the placenta either with the finger or an instrument, that has not been cast off, there is great danger that a portion will remain attached, and keep up a constant hemorrhage for days and weeks, and cause far more trouble and danger than to adopt the plan just proposed. I think there is far more danger both of hemorrhage and septicæmia from the retention of a portion than a whole placenta: in fact, so long as the placenta remains entire and attached, there is no danger from putrid absorption, for there is no decomposition. If the placenta is not expelled within twelve or eighteen hours, it will usually remain about a week, when hemorrhage will set in and the placenta will be found in the neck and can be hooked down without any trouble. Occasionally a placenta will be retained for several months without hemorrhage or any unpleasant symptom. I remember one case when it was retained for three months, and when expelled bore no evidence of decomposition. In one case recorded the placenta of a five months' fœtus was never expelled. This patient had no hemorrhage, no lochia, but was troubled with a tolerably profuse leucorrhœa for several months and general debility. Her health became completely restored, and she has borne several children since.

Besides the danger from hemorrhage and septicæmia, a retained placenta may undergo hydatid degeneration, or if small, it may become the nucleus for a polypoid growth; therefore, if not expelled within reasonable time, it is better to dilate the cervix by tents, and remove it, than to risk the dangerous consequences of its retention. Ergot used for this purpose will be unsuccessful, except the cervix first be dilated, then no doubt it will assist both in controlling hemorrhage and expelling the contents of the uterine cavity.

The treatment by preventive measures I have only alluded to in cases where symptoms of abortion are already present. The time for successful treatment is in the intervals between gestations, and after pregnancy has taken place, before symptoms have manifested themselves.

To be successful, a thorough knowledge of the history and causes of previous miscarriages is essential

it depends upon the bad condition of the patient, ch measures as will improve her general condition ould be prescribed. If from syphilitic influences, propriate treatment of both husband and wife may come necessary. If from uterine disease either of e os, cervix, or body, it should receive special atten- on, and an important part of the treatment consists requiring total abstinence from cohabitation for sev- al months, not only to avoid the irritation and ex- tement caused by the act if the patient is already egnant, but to avoid pregnancy and thereby give e organ complete rest, and a system reduced by pre- ous abortions time to rally. If from displacements, ey should be remedied by appropriate measures. If om excessive sensibility and contractility of the ute- ne fibres, it is particularly necessary that the organ ould have a long rest, and the advantages of change f air, sea bathing, and the use of arsenic should be nployed. When conception has taken place, there is ill time for much to be done both by treatment and dvice.

The plethoric patient can lose a little blood from the m every month with benefit, at the time when the enses would have appeared. If there is general ple- nora it is very necessary; if local, although the gen- al appearance of the patient may contra-indicate it, small bleeding will be well borne, and the danger of miscarriage very much lessened. Patients who have periodic discharge of blood from the uterus for the rst three or four months seldom miscarry. Nature elieves them of the local plethora.

I am not quite prepared to accept nature's suggestion nd apply leeches to the os after pregnancy has com- enced, but I once had the good fortune to carry a atient safely through her pregnancy, who had been ubject to numerous abortions, by applying leeches to he os after pregnancy had advanced two months, to elieve what I supposed was a local plethora—being nconscious at the time of her pregnant condition. The feeble anæmic female needs mild exercise in the pen air, and the long continued use of iron; and if she uffers from leucorrhœa and a soft relaxed os, daily stringent injections, or the use of astringent vaginal uppositories. The chlorotic patient will be benefited y the use of iron and the chlorate of potash. An ir- itable condition of the uterus may need frequent ano- lyne enemata per rectum. Irregularity of the bowels, ither constipation or diarrhœa, needs attention. Syphilis either in the man or woman requires a care- ul and long continued mercurial course of treatment. I have no knowledge of, or faith in, any special reme- lies to prevent abortion, except mercury in syphilis. Sautn highly extols the use of savin in 15 grain doses, hree times a day, for three or four months, to correct he pernicious habit; and Simpson and subsequently Barker of this city are equally as sanguine in the use of the chlorate of potash in large doses and long con- inued. I have given the latter remedy a thorough rial several times, but it has failed to meet my expec- ations. The quantity recommended is so great that I find difficulty in getting my patients to persevere with it. The only cases in which it seems applicable are nnæmic females. To such I still give the chlorate in smaller doses, and in conjunction with iron, with be- nefit. I am well satisfied that many cases of threat- ened death of the fœtus from defective nutrition, caused by impoverished blood or by defective placen- tal circulation, either from too small a placenta or fatty degeneration, have by the use of this treatment been carried safely to the full term.

Dr. Fordyce Barker exhibited a specimen of in- terest, a perfect and entire ovum, expelled at about the fifth month of gestation, with the placenta attached. The mother, 42 years of age, had had four children, the eldest 16, the youngest 7, since the birth of which she had not been pregnant until the present time. She menstruated Aug. 3d, and supposed that her period recurred again Oct. 3d, missing Sept., but in Oct. the loss was slight for two days only. Nov. 15th, she again had a loss of blood for two days. As the symptoms which accompanied former pregnancies were absent, she did not believe herself to be preg- nant, but supposed that she was suffering from irre- gularities which were due to a "change of life." Her husband has been seriously ill for ten days past, and she had endured great fatigue and anxiety from this cause. Five days since, she began to lose some blood and complained of pain in the back, but with no symptoms of uterine contraction. She was advised to go to bed, and camphor and hyoscyamus pills were given to induce sleep, as opium produced in her the opposite effect. At hast-past eight yesterday morning, the entire ovum was expelled after an hour and a half of severe labor. The duration and intensity of pain she described as being quite as severe as the labors at full term of gestation. Her husband, who is convales- cing from severe illness, when giving his consent to have the specimen taken away, facetiously remarked, that he supposed that the doctor wished to add to his medical bill his services as undertaker.

Dr. Barker then discussed, with some minuteness of detail, certain points in the paper of Dr. Church. He was firmly convinced that a healthy ovum is not easily separated from a healthy uterus. One of the very few points, in which he should feel obliged to dissent from the author of the paper, was that abortion was ever due to a "habit of the system." The term only cov- ered our ignorance of the real cause of the death and expul-sion of the ovum, at a given period in repeated pregnancies. In the progress of science, in those cases where the cause of these repeated abortions cannot be explained by any known condition of the maternal system, constitutional or local, or by any known patho- logy of the ovum itself, we may yet discover what the real disease of the ovum is. The pathology of the ovum and the placenta is yet to be fully studied. In the five years which had elapsed since he read a paper on this subject which was published in the Medi- cal Record, June 1st, 1868, he believed that he had acquired some additional knowledge from a careful study of the cases which had come under his observa- tion, but all must admit that the symptoms indicating dis-ease of the ovum are very obscure and the diagnosis of these diseases very difficult. He related one case illustrating this point. A lady, who had five times mis-carried between the sixth and seventh month, came to this city from San Francisco, with the anxious hope that she might give birth to a living child in her sixth pregnancy. She was first seen by the doctor on the 16th of September. She had the appearance of perfect health, and the most careful investigation failed to elicit any information which would explain the cause of her previous miscarriage. She was now, as she sup- posed, about six months pregnant. The sounds of the fœtal heart were very distinct. There seemed no in- dication for treatment, and the patient seemed some- what disappointed when told this by the doctor. On the 28th of Sept. he was again called to see her and found her extremely despondent, saying that she felt exactly as she did when her previous miscarriages oc- curred, but she had no symptoms indicating such a danger, except that her countenance was anxious and worn, her pulse was quick, and her temperature 100°. The sounds of the fœtal heart were distinct. The next

morning her moral depression was great, her pulse 112, her temperature 103°, and her tongue white. The sounds of the fœtal heart were feeble and too rapid for him to count. But she had no hemorrhage, no uterine pain, but an obscure, ill-defined pain and weight over the lumbar region. Abdominal palpation gave entirely negative results. The urine had been examined by Dr. Flint, Jr., and pronounced normal. A vaginal examination revealed no abnormal condition of the cervix, but pressure upon the posterior wall of the uterus caused pain, and the rectal touch gave a peculiar boggy sensation to the finger and caused faintness and nausea. These were absolutely all the signs and symptoms that could be ascertained. Placentitis was suspected, and the patient was with some difficulty persuaded to submit to venesection. About 16 ounces of blood were taken from the arm, and it was to him very interesting to remark, that after the bleeding the sounds of the fœtal heart were much more distinct and were easily counted as 140 per minute. She was kept in bed for a few days, but afterwards she was advised to go out and take exercise as much as possible short of great fatigue. She was given chlorate of potash in twenty grain-doses, three times a day. She took eleven ounces of the chlorate between this time and the period of the labor. Dec. 28th she was delivered of a perfectly healthy girl, weighing 6½ pounds. It was very thin, but vigorous, and has grown fat rapidly since birth. On examination of the placenta, there was a colorless fibrinous deposit, nearly two inches in diameter, in the centre of the placenta. There had evidently been a circumscribed centric placentitis.

As to other points in the paper, Dr. B. could not speak from personal experience as to the use of ergot as a prophylactic against abortions, but many writers concurred with the author of the paper in recommending it for this purpose. He never used the ergot to facilitate the expulsion of a portion of retained ovum, but chiefly used it to promote involution in those cases of passive hemorrhage which are sometimes met with after abortion. He had used the ergotine hypodermically for this purpose. His experience had not been favorable in using this agent in alcoholic solutions as recommended by some German writers, as Hildebrandt, Drasch, Langenbeck, as the injection caused severe local pain, and in two instances was followed by troublesome abscess. Dr. B. used ergotine ℈ij; aq. puræ, glycerine, aa ℥ij.—six drops then contain one grain of ergotine. But on the whole, he was disposed to believe that he got just as good results from the ergot, when used as rectal enema, two drachms of Squibb's fluid extract with an ounce of thin starch or arrow-root—thrown and retained in the rectum. He agreed with the author of the paper in the belief, that the mistake was sometimes made of keeping the patient too long in the recumbent posture, to prevent a tendency to abortions. Everything which enfeebles the general health increases the liability to abortion.

He referred to the error of assuming that the ovum is dead from the amount of blood lost, to the use of opiates, astringents, the tampon and other measures, and concluded by expressing his assent to most of the doctrines advocated in the paper which had been read, and his appreciation of the author's honest, conscientious work.

The Academy then adjourned.

THE WATER TREATMENT OF CHOLERA.—M. A. Netter, M.D. (*Gazette des Hôpitaux*), has a paper on the treatment of cholera by the administration of water in large quantities.

Correspondence.

A REMEDY FOR INFLUENZA.

TO THE EDITOR OF THE MEDICAL RECORD.

ALLOW me, through the columns of the RECORD, to give to my professional brethren a simple remedy for a prevailing disorder which causes a large consumption of pocket-handkerchiefs, and an ineffectual use of strong language by the patient. I have found the following combination to cut short an attack of severe influenza in ten hours:—

℞ Carbolic Acid. . . .gtts. x.
Tr. Iodine }
Chloroform } . . . .āā ℥ij

A few drops of this mixture are to be put in a test tube, and the same heated by a spirit lamp; when volatilization occurs the mouth of the test tube should be held beneath the nostrils. This operation is to be repeated every two or three hours. A violent fit of sneezing occurs at first, which is afterwards succeeded by a diminution of the symptoms.

ALLAN MCLANE HAMILTON, M.D.

114 East 30th street. February 17th.

BENNETT'S METHOD OF REDUCING DISLOCATION OF THE SHOULDER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—A writer in the October No. of the *American Journal of Medical Science* for 1872 scouts entirely the idea of the originality of my method of reducing a deep glenoid dislocation of the humerus, and says it was taught and practised by Dr. Physick as long ago as 1790, and that it is mentioned by Prof. Hamilton in the fourth edition of his exhaustive treatise on Fractures and Dislocations, page 553. It may have been so taught and practised by Dr. Physick, but though I have at least a respectable surgical library, I do not find any mention made of it, and certainly Dr. Hamilton does not mention it, if I can understand the English language. It is true that Dr. Physick did recommend fixing the scapula in the way I propose, and fixing the scapula by pressure against the acromion is recommended by Dr. Hamilton, and this is all there is in common with my process. But what next? Neither recommends the extension in the manner practised by me. Prof. Hamilton proposes to fix the scapula by pressing against it with the foot, and then extending—how? Not downward in a line with the body, as recommended by me, but by carrying the arm outward. Dorsy and Hayes also speak favorably of thus fixing the scapula, but do not, so far as I can learn, make extension downward in a line with the body, as practised by me. Others, it is true, recommend traction in a line with the body, with the patient flat on his back, with the heel in the axilla; but under such circumstances, no fixing of the scapula is done by pressure on the acromion, and therefore it is nothing like my process. Moreover, any surgeon who attempts to reduce a dislocation in this manner shows most conclusively that he has not studied the anatomy of the shoulder-joint, or, if having studied, has failed to profit by such study; for of all the different methods resorted to in reducing this dislocation, I consider this the worst, being the least likely to succeed, and the most liable to do lasting injury to the joint. I therefore claim that, taken as a whole, no such method was ever devised or practised by Dr. Phy-

ick, or recommended or described by Dr. Hamilton; nd that, taken as a whole, I still claim it as originally ine; and I shall continue to claim it until the gen- leman, whoever he may be, shall adduce more proof o the contrary. I suppose it is wanting in etiquette or a country surgeon to claim to know anything, but I ave yet to learn that city limits contain all the nowledge in the world. "Tall oaks from little acorns row."

Truly yours,
E. P. Bennet, M.D.

Danbury, Ct.

THE ALTERATION OF PRESCRIPTIONS—A REPLY FROM THE COLLEGE OF PHARMACY.

To the Editor of The Medical Record.

N the January number of your Journal, a communi- ation appears from Dr. Barker, accusing some of our raternity of altering the prescriptions sent them by ubstituting other things than those ordered, or reduc- ng the quantities of expensive remedies when ordered. At once the public press (only too glad to seize the op- portunity) raise the "hue and cry" of "new dangers rom druggists."

While it is conceded that in our own profession, as vell as in the medical, legal, and editorial, may be found some who are incompetent, dishonest, and un- principled, yet it is proper that a reply should be made o Dr. Barker's article.

The College of Pharmacy of this city, at its meeting of Trustees in January, appointed a committee to wait upon Dr. Barker, and obtain definite information as to the complaints made, in order that the offender, if a member of the College, should be punished. The committee called upon Dr. Barker, and informing him of the object of their call, he stated that he could not name the person who reduced the quantity of quinine, &c., in prescriptions, as his authority was from a med- ical student, and not from a clerk employed in the store, though he had at the time no reason to doubt the veracity of the informant, while the person who made the error in dispensing "Tully's Powder" had been dismissed by his employer, and he thought that should end the matter. The committee reported the result of the interview with Dr. Barker at the Trustees' meeting in February, but from their inability to give any positive information as to whether there was any informality on the part of any member of the College, the subject was necessarily dropped. This will ac- count for the delay in replying to the article of Dr. Barker.

The committee believe that but very few, *if any*, would descend to such paltry and disreputable means of enlarging their profits. In regard to "Tully's Powder," they would say that it is an article unknown to many druggists, and the formula for its preparation is not in any of the text-books usually to be found in the library either of the druggist or physician. By this statement, the committee do not, however, wish to appear as exculpating the offender or palliating the of- fence. It would be well if such formulæ were written in full in prescriptions, and not designated by a "local" name or a formula unknown to many druggists.

The attention of the medical profession of this city is called to the fact, that if they *know* of any dereliction of duty on the part of any druggist of this city, who is a member of the College of Pharmacy, by mak- ing such fact known to the officers of the College it will be at once investigated, and, if true, the offend- ing member will be punished by expulsion. If they know of incompetent assistants who have not been ex- amined by the Board of Pharmacy, then that Board should be informed of the fact, and it will do its duty. There are better remedies for the troubles alluded to by Dr. Barker than rushing into print, and writing bitter things against those whom, as a body, they will find desirous to faithfully execute the wishes of the physician. Appended will be found a copy of the "Code of Ethics,"* to which the attention of physi- cians is called.

The closing paragraph of Dr. Barker's communica- tion we reprint: "Our only safety is in sending our prescriptions to those druggists whom we have found to be thoroughly competent and trustworthy, and in a careful examination of the medicines after they have been prepared."

To the first portion of the paragraph we heartily assent, and if the profession would adhere to this, our city would be freed from some who are a source of annoyance to both the medical and pharmaceutical professions, while the worthy and competent would reap a better reward for their services. This is the true remedy; but let the physician remember that "com- petent and trustworthy pharmacists" are as likely to be found in the humbler and less decorated stores of our city, as in those of "marked pretensions as to ex- ternal display." In regard to the "careful examina- tion of the medicines after they have been prepared," it is safe to say that not one physician in ten could prepare a majority of his own prescriptions, nor be able to judge properly as to whether it is correctly dispensed. It would be well if the medical students of the present day could devote some of their leisure hours to the practical details of the drug-store, or attend lectures on practical pharmacy. Then they may be able to judge whether their prescriptions are accurately dispensed, but hardly otherwise.

On behalf of the Board of Trustees of the College of Pharmacy.

By the Committee.

---

* Code of Ethics of the College of Pharmacy of the City of New York, adopted at the meeting, October 18th, 1871.

Preamble.—The members of the College of Pharmacy of the City of New York, considering it necessary that some mutual understanding should exist in regard to the moral principles guiding them in their profession, hereby agree upon the following Code of Ethics:—

1. We accept the U. S. Pharmacopœia as our standard and guide for all officinal preparations, and recognize a variance from its rules only in exceptional cases, where sufficient authority has proved some other process more reliable to attain the same end.

This section is not intended to interfere with the dispensing of Prescriptions or Medicines ordered in accordance with foreign Pharmacopœias.

2. Although not a legitimate part of our business, custom and the necessity of the times warrant us in keeping the proprietary medicines of the day, yet we earnestly recommend Pharmacists, when called upon for an opinion of their merits, to discourage their use.

3. We discountenance all secret formulæ between physicians and pharmacists, and consider it our duty to communicate such to each other when requested.

4. We distinctly repudiate the practice of allowing physicians a percentage on their prescriptions, as derogatory to both professions.

5. We will endeavor, as far as lies in our power, to refrain from compromising the professional reputation of physicians, and we expect the same comity from them.

6. Since the professional training of the pharmacist does not include those branches which enable the physician to diagnose and treat disease, we should, in all practicable cases, decline to give medical advice, and refer the applicant to a regular physician.

7. The growing demands of the age require that those who follow the profession of pharmacy should be educated up to a higher standard. Therefore, we consider it our duty, individually and collectively, to encourage the advancement of knowledge in our profession generally, and particularly by stimulating our assistants to attend the lectures of the college, and by aiding and assisting them to do so.

8. Considering it expedient that some rule be adopted to enforce the provisions of our Code, we hereby agree, if any just cause of complaint of its violation be found against a member of this college, to bring the case before a special or the next general meeting of the college, when the accused, after being heard in his own defense, may be expelled by a two-thirds vote.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of Medical Department, United States Army, from February 5, 1873, to February 18, 1873.

SUMMERS, JOHN E., Surgeon.—Granted leave of absence for 15 days, from 12th inst. S. O. 23, Department of the East, February 6, 1873.

BILL, JOSEPH H., Surgeon.—Leave of absence extended 30 days. S. O. 30, War Department, A. G. O., February 8, 1873.

Medical Items and News.

JAMES LIVINGSTON BROWN, M.D., lately deceased in this city, was born in New Jersey in April, 1831, and moved with his parents to New York City while he was an infant. The intelligence, perseverance, and integrity which have made him so highly esteemed in his professional relations, were also characteristics of his youth, and secured for him even then many friends. One of these friends furnished him the instruction requisite to enter Columbia College, from which he took his degree in Arts in 1852. He immediately commenced the study of Medicine with Dr. Alfred C. Post, and in 1856 graduated at the Medical Department of the University of the City of New York. During his course of study, in both Arts and Medicine, he supported himself by playing the organ, on which he had become an accomplished performer, and the same resource served to defray, in part, his expenses during the earlier years of his practice.

In 1861 he became an attending physician to Demilt Dispensary, holding in succession positions in all but two of the departments, and for several years before his death had attended to that of "diseases of women."

In 1867 he became attending physician at the New York State Woman's Hospital, and continued in this capacity until his resignation in the spring of 1872.

At the establishment of the Strangers' Hospital, in 1870, he became the assistant visiting physician to the lying-in department and the department of diseases of females. He was also visiting physician to the St. Luke's Home for Indigent Christian Females.

In 1869 he became clinical assistant to the department of obstetrics and diseases of women and children, in the College of Physicians and Surgeons, Medical Department of Columbia College.

He was a member of the New York Society for the Relief of Widows and Orphans of Medical Men; of the New York Pathological Society; of the New York Academy of Medicine; of the New York Obstetrical Society; and of the Medical Society of the County of New York.

For a few days preceding his illness he was attending a case of typhus. On the 1st of February he was attacked with a chill followed by high fever, and until two days later his symptoms were obscure; then, however, pneumonia became evident, and the typhoid symptoms becoming more intense, he died four days from the date of his attack.

NEW YORK ACADEMY OF MEDICINE.—At a stated meeting of the Council of the Academy of Medicine, held January 28th, 1873, Bradford S. Thompson, M. D., was elected Statistical Secretary of the Academy for a term of five years from this date.

POUCHET.—M. Felix Archimede Pouchet, the renowned zoologist of Rouen, and the great advocate of spontaneous generation, died recently, aged 74 years.

DEATH OF HOLMES COOTE, F.R.C.S.—This senior surgeon to, and lecturer on surgery at, St. Bartholomew's Hospital, London, died with paralysis, December 22d, 1872. Mr. Coote was an excellent teacher, a clear-headed anatomist, and accomplished surgeon. Holmes' "System of Surgery" has much of his valuable writings.

MEDICAL LIBRARY AND JOURNAL ASSOCIATION OF N. Y.—At a session of this Association, held January 10, 1873, Dr. John C. Peters, President, in the chair, Dr. Bradford S. Thompson read a paper on "Scarlet Fever," dwelling principally on the *history, pathology, propagation, prevention* and *treatment*, based upon the latest researches of home and foreign authors, and his own observation. The paper will be published in full elsewhere. It was fully discussed by the President, Drs. Burrall, Hubbard, Foster, Garrish, Messenger, and others. Dr. Peters related unique cases illustrating its contagiousness, spoke of the importance of inunction, which should be observed from the first day, and the danger of carrying and propagating the disease by the physician; only in cases of convulsions with a fully developed rash would he employ cold affusions, and then at a temperature of not less than seventy degrees. Dr. Burrall particularly referred to cases of the fever in which the only symptom exhibited was a sore throat, showing that sore throats should be carefully watched. He advocated, as a gargle, the following combination: Bromo-chloralum, glycerine, each a teaspoonful in a tumbler of water. Dr. Hubbard approved of the tinct. perchloride of iron and digitalis in dropsical cases, and would discard blood-letting and the use of leeches in the general treatment, and showed the importance of good air, isolation, and open grates in the sick-room for ventilation. Dr. Foster relied mainly on the sustaining treatment from the first, and orders plenty of milk. In dropsical cases he would rely on gallic acid and tinct. ferri chlorid. As an unguent he advocated leaf-lard. Dr. Garrish was pleased to learn that New York was not the most unhealthy city in the world. As a rule his patients were carefully isolated from the wall, and fed on brandy and milk. He thought many cases were originated through the carelessness of the physician and defective disinfection.

LACERATION OF THE PERINÆUM,

INVOLVING THE SPHINCTER ANI, AND OPERATION FOR SECURING UNION OF THE MUSCLE.

By THOMAS ADDIS EMMET, M.D.,

ATTENDING SURGEON OF THE WOMAN'S HOSPITAL, STATE OF NEW YORK.

(Read before the New York County Medical Society, January 27th, and State Medical Society, February 4th, 1873.)

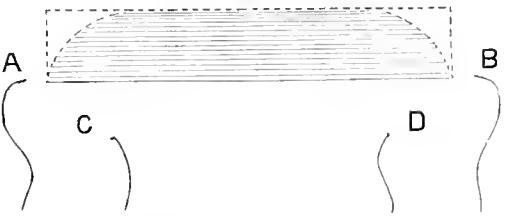
It is not my purpose to enter at length into a consideration of the causes of laceration of the perinæum. It is, however, of no little interest to determine how far a difference in shape and depth of the pelvic outlet, meddlesome midwifery, or other causes may render women liable to a lesion from which other animals are, as a rule, exempt in giving birth to their offspring. When the laceration has been so extensive as to involve the sphincter ani and a portion of the recto-vaginal septum, it is the result generally of instrumental delivery. While this accident is the exception, and may occur in the hands of a most skilful operator, we have too often the evidence to doubt its frequent occurrence from untimely interference, faulty instruments, and a lack of skill. Many of the profession attach but little importance to a loss of the perinæum, and regard a laceration, to a greater or less extent short of involving the sphincter, as a natural consequence of child-bearing. If this be so, woman has not been favored.

Laceration of the perinæum down to or involving the sphincter, sooner or later must affect the normal position of the uterus, by allowing a prolapse of the posterior vaginal wall, that of the anterior wall being secondary to a change of position in the organ. When a female is standing upright, a perpendicular line drawn from in front of the sphincter ani will intersect the os uteri, if the organ is in its normal position. By the use of Sims' speculum, or any other perineal retractor, we demonstrate the relative position of the uterus, for the cervix is exposed in this perpendicular line. Were a female to stand on her feet with the perinæum thus retracted, the uterus would drop through the vulva, were it not retained by the tonicity of the vaginal walls and the connective tissues of the pelvis. There are causes at work to explain the fact that often a long period of exemption exists, after extensive laceration, without any marked evil consequences following, while on the other hand we can trace directly to a want of proper perineal support results not always in keeping with the extent of injury. So long as the vagina maintains its integrity, due indirectly to its pelvic connections, there may be no symptoms presenting themselves for interference, the female remaining only liable to the occurrence of some future difficulty as a consequence. While the uterus remains in position and the vagina retains a natural size, the walls of the latter lie in close contact so as to exclude the atmospheric air. As the vagina becomes relaxed, with its outlet unnaturally open or patulous, the external air is drawn within the canal to a greater or less extent with every movement of the body.

This is a source of great annoyance, for on making any quick movement of the body, as turning suddenly in bed, the air retained within the canal becomes forcibly expelled, as the escape of flatus from the anus. Should there have been no previous indication of trouble, it would be now unwise to delay longer closing the perinæum sufficiently to give a firm support to the posterior wall of the vagina, without reference to other treatment which may be called for. As I wish to direct the attention of the Society more particularly to the mode of securing a union of the lacerated sphincter, it will be unnecessary to enter into detail of the more simple operation for closing the perinæum, and which would be in part but a repetition.

When the perineum and the muscular ring forming the sphincter ani has been divided, a gaping triangular opening is left, the base of which would be formed by the lacerated muscle and the apex by the limit of the laceration in the recto-vaginal septum. For the convenience of demonstration we will describe the shape of the divided sphincter as a parallelogram. Gradually the muscular fibres retract in proportion as they have been freed. Consequently the fibres which have formed the inner surface of the circle, when in its integrity, will have shortened more than those on the outer margin which still remain attached to the surrounding tissues. A glance at the diagram will show

Fig. 1.



the corners rounded off, so as to present a convex surface, by this shortening of the inner fibres from the dotted outline representing a parallelogram, the original shape of the muscle just after the rupture. This shortening of the fibres has been overlooked by the profession, and in cases of long standing is the cause, after an operation, of failure in gaining entire control over the escape of flatus and the contents of the bowels when in a fluid state. As the operator only extends the denuded surface from above to A B, the apparent limit of the laceration, but a small portion of the ends of the muscle can ever be brought in contact. In a large number of cases not a fibre of the muscle is united, although the perinæum may have been restored and the laceration through the recto-vaginal septum closed by the operation. To unravel the cause of failure and to devise the means of obviating it has occupied my attention for years. To appreciate so simple an explanation has cost me more thought than any other point in the whole field of the branch of surgery to which I have devoted myself.

The success of the operation is due to the point at which the first suture is introduced in relation to the edges of the divided muscle. If the first suture be entered on the line and a little outside of A B, Fig. 1, at the point which would seem most appropriate, but a small portion of the muscle could be approximated, as shown in Fig. 2, and incontinence to some extent must be the consequence.

Introduce the suture, however, at some distance behind the muscle, toward the coccyx, at the points C D, Fig. 1, and we see at a glance, by Fig. 3, that on securing the suture the divided edges of the sphincter must be turned up and brought in perfect apposition.

I will now briefly describe the operation. The patient should be placed on the back, with the legs flexed on the abdomen, and held by an assistant on each side. The surfaces which have been lacerated, and to

be denuded, are generally well mapped out by a slight cicatricial glaze, and under ordinary circumstances,

Fig. 2.

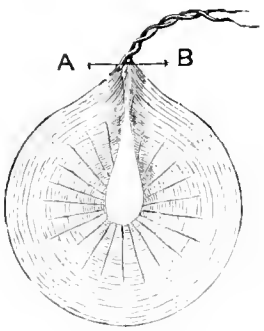


Fig. 3.

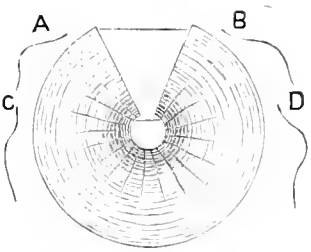

without sloughing has occurred, there can be but little difficulty in determining the extent. I prefer the use of a pair of slightly curved scissors to the knife; the surfaces can be removed with greater despatch and with less loss of blood. The denuding should be commenced from the most depending point, and extended upward so as to be free from the annoyance of blood flowing over the surface to be freshened. If we examine carefully the extremities of the lacerated muscle, we will find a slight pit or depression at each end, which has been caused by the contraction of a portion of its fibres. It is necessary to freshen these surfaces, for by doing so we denude the ends of the muscle, and on that side of the depression go over to a great extent the surfaces included between the dotted angles shown in Fig. 1. At the commencement of the operation, seize with a tenaculum a portion of the tissues at one of these points, with the scissors remove a narrow strip entirely around the laceration to the opposite end of the muscle, and as close to the edge of the rectal mucous membrane as possible without wounding it. One strip after another is to be thus removed until we reach the neighborhood of the caruncule above. If there should be a partial prolapse of the posterior wall, it will be necessary to extend backward the denudation on the vaginal wall sufficiently to turn in the excess of tissue and gain a firm support with the perinæum. I have long since exhausted my ingenuity in devising hollow needles of various curves to convey directly the wire and needles of different shapes and size. I have settled down to the use of an ordinary stout needle, about two inches in length, straight, or with but a slight curve near the point. A needle with a large curve would be best adapted for this operation, but without it be made square towards the eye it is apt to turn in the grasp of the forceps or break by bending. If a hollow needle is used, shaped as an awl, but with a larger and a double curve, it is as difficult to direct its course without greatly increasing its diameter. This is objectionable, for, in such vascular tissue, the risk of thrombus, and abscess afterwards, is greatly increased if the calibre of the passage made by the needle is much larger than necessary for the reception of the silver wire. If a simple needle is used it should be armed with a double silk ligature, secured from slipping by a half-knot at the eye.

With the index-finger of the left hand in the rectum to serve as a guide, the needle is introduced behind the muscle to the left, at the point D, and made to sweep around the angle of laceration in the septum to the point of exit at C, by gradually rotating the forceps. As the point punctures the skin in its exit, the index-finger is withdrawn from the rectum to aid the passage of the needle, by sliding back the tissues sufficiently for it to be seized by the forceps and drawn through. The second suture is introduced just outside of the end of the muscle, and in the same plane with the divided rectal edge. The third suture is to secure the vaginal edge of the laceration. It should be made to include the tissues liberally, and to sweep around the angle at some distance beyond the first and second suture, as this one is most liable to cut through the recto-vaginal septum.

The third and fourth suture would bring together the portion denuded on the posterior wall of the vagina, with the view of increasing the depth of the perinæum. Should the prolapse have been more extensive, so as to need the operation for rectocele, the denuded surfaces on the septum should be secured by interrupted silver sutures extending within reach of those intended to form the perinæum. If these sutures in the vagina are properly bent flat to the surface, they may remain undisturbed twelve or fourteen days. They can then be removed while the patient lies on the back, using a small-sized Sims' speculum introduced under the arch of the pubes. If the necessity does not exist for making the perinæum unusually thick and strong, the fourth and fifth sutures are merely passed through one labium and across through the other. A portion of silver wire is to be twisted to the end of each silk loop, and drawn through in turn. It is necessary to secure first the lowest suture, C D. This is done by seizing the ends of the wire at a proper distance, so that the index-fingers may be used to slide the tissues firmly down on the suture, as moderate traction is made with the hands. The suture is then secured, without relaxing the traction, with several half-turns made by reversing the position of the hands from one side to the other. Each suture is thus in turn secured from below upward. Experience can alone indicate the proper amount of tension to be made, and success to a great degree will depend upon this manœuvre. The parts should be just brought in apposition, and no more, for in a few hours there will be sufficient swelling to force the tissues in close contact. If the sutures have been twisted too tight, and especially if they have been introduced in too superficial a manner, they will cut out from behind forward, so as to leave a recto-vaginal fistula, or the tissues in front will have become sufficiently strangulated to set up some inflammatory action, resulting afterwards in a labial abscess. I am in the habit of twisting the sutures, and cutting them off some three or four inches in length. These are then secured together, as the radii of an open fan, by twisting a loop of wire around their ends. This loop is prevented from slipping off by bending over and backward a portion of one of the sutures, and the ends of the others are cut off at an equal length. This arrangement keeps the sutures stationary and guards against a common source of inflammation from violence, to which the separated and unprotected ends would be constantly exposed, when

too short. The patient is placed in bed on the back, with the knees tied together and a pad between them. The after-treatment may be summed up in a few words.

If the bowels have been thoroughly acted upon previous to the operation, they may remain undisturbed for twelve or fourteen days without discomfort. The diet should be so regulated, and opium administered when needed in sufficient quantity, to keep the bowels quiet. The chief care is in emptying the bladder, so that the urine is not allowed to drip from the catheter on the uniting surfaces below. If the urine, even in small quantity, is permitted to pass backward into the vagina, it will find its way readily between the denuded surfaces, and when the sutures are removed it will be found that but little or no union has taken place. With an inexperienced nurse, I have the bowels moved by castor-oil on the sixth day, and remove the sutures a day or two afterwards. With a nurse accustomed to the operation, I withdraw the sutures in a week and have the bowels moved a few days after, for the nurses learn to support the parts with their fingers while the bowels are acting, so as to relieve the recently-united surfaces from all strain. It is a good plan to have a small quantity of warm olive-oil gently thrown into the rectum just before the bowels are moved. When the sutures are to be removed, the precaution should be taken to draw them out across the buttock, on that side of the loop which has been cut, so that the parts will be kept in contact by the suture until its withdrawal. It is necessary that the knees of the patient should be kept tied together for several days after the sutures have been removed, and always at night for some time longer. A few days after the operation the position may be changed from the back to the side, provided that the sutures are protected, and the move can be made by the nurse without effort on the part of the patient. Between the second and third week the union will be firm enough to allow the patient to sit up, but she should be instructed to keep her limbs together as much as possible, for although there may now be but little fear of laceration, yet absorption will rapidly take place if a sufficient amount of traction is exerted.

It is important that we should consider more in detail the action of the first suture, on which so much depends. As this suture runs backward, obliquely across the diameter of the rectal extremity, it seems impossible that it could be secured without shutting up the anus. This, however, is deceptive, for the ends of the muscle must be drawn upward on tightening the suture passed above through the recto-vaginal septum, which is a fixed point to a certain extent. The relative position of this suture is shown in Fig. 3 to be above the anus when twisted, and as the rectum turns immediately backward into the hollow of the sacrum, the outlet is in no manner encroached upon. When this suture is secured, its tendency is to roll upward and outward the tissues from the rectum towards the vagina, and to bring below the edge of the laceration a portion of undenuded mucous membrane of the rectum in contact throughout its course. This suture therefore, along the rectal portion, acts as a safeguard in relieving the second suture from tension, and is a protection against the tendency of flatus to force a passage through into the vagina. In my former operations, this second suture, passed on a line with the edge of the laceration through the rectum, was the first and main stay. I then frequently noted as the other sutures above were secured, that the tissues were forced downward with the effect of springing apart, as it were, the loop of this the first suture, and a large portion of denuded tissue became rolled out into the rectum. The result was the frequent occurrence of a smal recto-vaginal fistula at the thinnest point in the septum. This opening was generally just behind the sphincter, and difficult to close from the constant action of the muscle, so that I generally divided anew the recently united perinæum and sphincter, denuded thoroughly the edges of the opening, and closed the parts again as in the first operation.

It is now some two years or more since I appreciated fully and have practised this method of operating. In this time I have had eleven cases with more or less extensive laceration of the septum beyond the sphincter. I am happy to state that I have not had a failure out of the whole number; they were all, however, patients in public or private hospital practice, where I have had the advantage of thoroughly trained nurses. Two out of the number at least have borne children since and were patients in private practice. One was a patient of Dr. J. B. Nelson, of the city of New York, who was present at the operation, with Dr. T. G. Thomas. This lady had married late in life and had been delivered by forceps of her first child in Florida, a few months before she came under my care. There was yet but little prolapse of the posterior wall or of the uterus; but it was an unusual case, for the laceration was double beyond the sphincter, leaving a long tongue of tissue between, which was cicatricial in character from sloughing. The parts were brought together in the usual manner; three sutures were made to traverse the flap, but when these were secured there existed an unusual amount of tension. Union however took place throughout, leaving a good firm perinæum. She was delivered without difficulty, by a natural labor, of a large child about a year after the operation, and has since been well.

The other case was a lady sent me by Dr. G. F. Carmichael, of Fredericksburg, Va. The laceration extended an inch beyond the sphincter, with a rectocele and the os uteri presented at the vaginal outlet. She had been delivered nearly a year before by forceps of her first child, which was of an unusual size. I was obliged to devote several months, while she was under daily observation, to reducing the size of the uterus and healing an extensive erosion with endometritis. The operation was successful, and shortly after her return she became pregnant.

Dr. Carmichael has since informed me that she was delivered, after a natural labor, of a large child, that not the slightest laceration took place, and that she has since been in excellent health. I have no doubt pregnancy has occurred in some of the other cases, but if any bad result had followed the delivery I am certain that I would have been informed of the result. In my experience, from previous operations, not a single instance of laceration has occurred in the line of union. I have had several instances where partial laceration has recurred from the same exciting cause which has existed, but it has always been to one side or on the other of the line united by the previous operation.

One point more, and that in reference to the proper time when the operation should be performed. When the laceration has extended through the sphincter, my conviction is that in every instance where it is possible to do so the parts should be brought together immediately after delivery. It is true, observation has taught us that the lochial discharge is poisonous to a healing surface, yet a large number would be successful with a little additional care. The operation would then be comparatively a simple one, as the muscular fibres have not become atrophied, and it would be unnecessary to pass the suture behind the muscle. Something would be gained in every case, and support would be given

to the uterus, for a while at least, until it had become somewhat reduced in size, and time gained for the overstretched vaginal tissues to recover in part their tone. A week thus gained, in giving a proper support to the parts at this time, may be the means of saving the patient from the necessity of undergoing treatment for months to reduce the size of the uterus,—this she may be spared, even if the operation itself should prove a failure.

At the reception of the injury the rent through the septum is more extensive than after the edges have cicatrized. If proper care has been taken by injections to keep the parts free from irritating discharges, the edges will generally unite to within a short distance of the sphincter. My experience has been confined almost exclusively to the treatment of cases some time after the parts have healed, and I have met with but few instances among them where the fissure remaining in the septum could not be included within the deep sutures passed as I have described. When the exception has existed, I have denuded the edges and brought them together down to the sphincter with a sufficient number of interrupted sutures. I have then afterwards closed the perinæum by a subsequent operation, or performed both operations together. For some years past I have followed the latter plan, passing the deep perineal sutures at a right angle to, and between, the three or four lower interrupted ones. The condition of the patient after delivery may be too critical to admit of the additional operation for bringing together the edges of an extensive laceration through the septum. Under these circumstances I should deem it advisable to introduce the deep perineal sutures, to include as much of the septum beyond the muscle as possible. If a union of the perinæum is thus gained, with a portion of the septum beyond the sphincter, but a small recto-vaginal fistula will remain. This may prove a discomfort, but its closure can be safely deferred. When an operation cannot be resorted to immediately after the injury, the knees should be kept tied together and the greatest care given by cleanliness to free the parts from irritation. Before the patient is allowed to assume the upright position, some mechanical support must be resorted to for the purpose of lifting the uterus from the floor of the pelvis, and keeping the organ partially anteverted, so that there may be no prolapse of the vaginal walls. After she has recovered her strength, if the child has been still-born, the operation should be performed without further delay. For the welfare of the child, if she be nursing, the operation should be deferred until it is old enough to be weaned with safety, provided the condition of the mother will admit of the delay by giving sufficient support to the uterus.

PERCY'S SO-CALLED ALKALOID HYPOPHOSPHITE.*

By EUGÈNE PEUGNET, M.D.,

NEW YORK.

It is certainly most gratifying to observe the rapid progress we are making in practical therapeutics by means of physiological chemistry—but we must not nullify it by adopting either preconceived ideas or an unsupportable hypothesis. Dr. S. R. Percy has again placed the profession under obligations to him, by presenting it with what may prove to be a valuable therapeutical preparation of phosphorus. I am well aware that some may cavil, as has been done in reference to his previous essays on digitalis, veratrum viride, etc.; but it must be admitted, that if those essays did not yield any practical results, still they were the basis of further researches, which have led to substantial ones.

Dr. Percy in his prize essay, "What Physiological Value has Phosphorus as an Organismal Element?" has given us an almost complete chemical history of phosphorus down to the present time; but we regret that he did not enter more fully into its toxicology. The essentially original part of the essay is that which relates to his so-called alkaloid hypophosphite. Basing himself on the well-known existence of lecithine, a neutral phosphoretted fatty matter which is found in the nervous tissue, fibrine, blood, bile, and yolk of egg; which is composed of nervine with one atom of each of the following acids: the oleic, margaric, and phospho-glyceric, is, therefore, an acid phosphate alkaloid, and not, as the Doctor asserts, a hypophosphite, for the phospho-glyceric ($C^6\ H^7\ O^7 + Ph\ O^5$) is composed of glycerine and phosphoric acid.

He has endeavored to form an analogous substance, an artificial lecithine, by dissolving phosphorus in a mixture of cocoa butter and Valentine's beef-juice, then by the action of pure oxygen to so oxidize the phosphorus as to form hypophosphorous acid, believing that each atom of it would, whilst in its *status nascentium*, combine with two units of the oil and one of nitrogen from the beef extract. This result would no doubt have been very gratifying, but I do not believe that the Doctor succeeded. As he was out of his alkaloid hypophosphite, I requested M. Ferd. Spangenberg to prepare some according to the Doctor's formula, which I know was accurately followed.

When prepared, I exhausted the preparation with water just warm enough to melt the theobroma, consequently much below the boiling point, 212° Fht.; the liquid thus obtained was of a pale sherry wine color. On subjecting it to the nitrate of silver test, the reaction indicated the presence of hypophosphorous acid, whilst the chloride of barium, acetate of iron, and acid nitrate of mercury tests failed to indicate the presence of a trace of phosphoric acid. In order to obtain a more positive result, I digested the liquid with animal charcoal, the purity of which I previously tested, as it frequently contains phosphoric acid, with a similar result. The exhausted theobroma was then subjected to Misterlich's distillation test, and utterly failed to indicate the presence of phosphorus. It is therefore evident that this preparation is *not an alkaloid*, but that *it is anhydrous hypophosphorous acid* dissolved in cocoa butter, which it would be utterly impossible to combine by any other known process.

Chemists have been heretofore indefatigable in their researches and efforts to prepare compounds of phosphorus, which they presume will be efficacious, and a few of which have, no doubt, a certain efficacy. *But in preparing their various combinations they obviously forget that the organism is a vast and complete chemical laboratory*, in which certain processes are constantly going on, and that it is not so much compounds that are required, as organismal elements for it to work on, and effect the chemical changes necessary for the process of assimilation. But there are certain conditions of the organism in which this process cannot be properly carried on; therefore the sound therapeutist, fully appreciating it, endeavors to meet the indications, and he is frequently at a loss for a proper preparation of phosphorus. The oleum phos-

* Prize Essay of the American Medical Association, 1872.

phoratum does not always answer. 1, its oxidation is but partial; 2, its administration is not always free from danger. The acid phosphates are certainly beneficial in certain gastric disorders accompanied with nervous depression, but are of little use in the more serious disorders of the nervous system. Phosphoric acid is the most effectual officinal preparation, and I believe far superior to the acid phosphates. The phosphite of zinc is excellent, owing to the rapidity of its action; but is objectionable on account of its odor and luminous properties when rubbed. Hypophosphorus acid has only been administered as a hypophosphite, but I doubt its efficacy when thus administered.

I believe that the preparation given to the profession by Dr. S. R. Percy will prove to be very efficacious. The cost of preparing it is small, it can be readily administered, and its odor can be disguised by capsules; but the most important advantage is, that it is given in an anhydrous form, and more readily absorbed when thus combined; and is no doubt decomposed, in the process of chylification, into phosphoric acid and phosphoretted hydrogen (the latter is a serious objection, owing to the eructations it may give rise to), readily combining with the oleic and margaric acids, and glycerine then acting upon the nervine or lecithine, that alkaloid which is the *sine qui non* of a sound nervous system.

The Doctor has also suggested that a liquid preparation similar to the first can be made with lard-oil. I have not experimented with it; but, reasoning *à priori*, I do not believe that the Doctor's hypothesis is more tenable than in the other; for it would be necessary to first decompose the olein into oleic acid and glycerine, and the margarine into margaric acid and glycerine; then the hypophosphorous acid in *status nascentium* would combine with the glycerine by decomposing itself into phosphoric acid and phosphoretted hydrogen, the former of which would with the glycerine constitute phospho-glyceric acid. Finally, the three acids would act upon the beef extract, take up its nitrogen, and form an artificial lecithine, which, it must be admitted, *is rather hyperbolical*.

It might be suggested that this lecithine could be extracted in its natural form from the brains of lower animals and fish. This is apparently plausible, but the same process which develops, forms it in their organisms, is also carried on in the human species. It is not absorbed as such, but is the result of chemical actions and changes constantly taking place in the organism, which we have been unable to fathom out as yet. Would it not, therefore, be much more *rational* to endeavor to introduce into the system its organismal elements in a form in which they will be readily assimilated? It is undoubtedly true that, in some cases, this process cannot be carried on; then, *à fortiori*, it is not probable that this alkaloid can be absorbed as such, for its very composition militates against it, unless the laws of digestion and absorption have been *misinterpreted*.

Proceeding beyond hypothesis, the Doctor has resorted to experiments which certainly demonstrate that this preparation of phosphorus is easily assimilated, and my own observations lead me to concur with him as to its great therapeutical value.

Case I. A gentleman, æt. 40, engaged in active business, involving great responsibility, and requiring a constant overstrain of the mental and physical powers, was affected with loss of memory, insomnia, inappetency, and vertigo; his urine was loaded with the oxalate of lime. His family history showed a tendency to brain disease in a marked degree. I gave him ten grains of Dr. Percy's phosphoretted cocoa butter three times a day; his improvement was so great that he indefinitely postponed a contemplated sea-voyage. About a year previously he was similarly affected, and the *phosphite of zinc* had as beneficial an effect. But the acid phosphates failed entirely.

Case II. A married lady, suffering from anæmia and nervous depression, with inappetency, insomnia, and a constant feeling of lassitude, rapidly improved under ten-grain doses administered three times a day.

Case III. A lady, æt. 73, had been suffering for six months with chronic diarrhœa of a malarial origin which had resisted all treatment. She was very much depressed, insomnia, inappetency, and marked tympanitic condition of the intestines. As the diarrhœa was evidently due, in a great degree, to the atonic condition of the intestinal tract, I combined one-twentieth of a grain of strychnia with six grains of the phosphoretted cocoa butter, three times a day; the strychnia was gradually increased to one-tenth of a grain. The improvement in her case was marked and permanent.

The Doctor administers this preparation in five-grain doses. I believe that it can be given in ten-grain doses, as each ten grains contains one-tenth of a grain of hyperoxidized phosphorus.

As there are no doubt many who would like to try this new preparation, they can procure it at Spangenberg & Boettcher's, corner 3d Avenue and 34th street, and at Spangenberg's, No. 1165 Broadway.

Original Lectures.

THE TREATMENT OF UTERINE DISEASE.

A LECTURE BY

PROF. A. J. C. SKENE, M.D.,

AT THE LONG ISLAND COLLEGE HOSPITAL.

Gentlemen—I shall make a few remarks at this hour upon the general *treatment* of uterine disorders. Heretofore I have spoken more particularly of their pathology and symptomatology. I begin with *corporeal endometritis*, and you will observe, if you follow me closely, that the treatment of this affection involves about all that is requisite in the management of the cognate malady, *cervical endometritis*. Before settling upon a plan of treatment, we naturally inquire what course the disease is likely to take if left without any treatment at all. In the present case, we have no difficulty in finding an answer to such an inquiry. Go into the hospital wards; watch the out-patient service of this institution; and you will gather abundant reasons for declaring, that neglected cases of corporeal endometritis do not, of themselves, tend to recovery. On the contrary, the constitutional symptoms generally increase in gravity, and not unfrequently the local trouble gets worse also. At the "change of life," when menstruation ceases entirely, and the final involution of the uterus takes place, benign diseases usually disappear; but under no other circumstances can we look for such a favorable termination. Active treatment, then, is necessary in order to relieve the hyperæmia, quiet the irritation, and restore the normal function of the organ. A few years ago, the teachers of medicine would have puzzled you with conflicting dogmas, and left you undecided whether to depend upon *local* or

constitutional measures of treatment. Happily to-day you are not to be placed in any such *limbo of doubt*; the judgment of the profession is that you shall make your treatment both *local* and *constitutional*.

Turning our attention to the constitutional treatment first, we naturally inquire if there can be found any medicines which, when introduced into the general circulation, will act directly on the mucous membranes of the uterine cavity, arrest morbid action, and restore the natural condition of the part. In other words, can we rely on any specific uterine medication in the case under consideration? This question must, I think, be answered in the negative. In your books you will find a host of remedies for menstrual derangements, leucorrhœa, and other uterine troubles; but you will discover sooner or later, I fear, that their virtues are greatly exaggerated; such, at least, has been my experience. Dr. Matthews Duncan, in treating of the hemorrhage that occurs in cases of uterine fibroma, declares positively that no medicines will control it; and the same statement may be made, with but little modification, in regard to menorrhagia arising from endometritis.

The great number of remedies employed in the treatment of this trouble is almost proof positive that none of them are reliable. A few years ago the iodide of potassium was greatly lauded in Germany by some who believed that it had a peculiarly curative influence in uterine leucorrhœa. From what we know of the action of this drug on mucous membranes in other localities, we might readily infer that it would act favorably in uterine disease; but, after having given it a fair trial in many cases, I must say that my hopes have been disappointed; I have not observed any very favorably marked results from the treatment. It may be worth trying, as an auxiliary, in cases of persistent leucorrhœa when the patient is of full flesh. Fat people, as a rule, bear this remedy best. But beyond this class of cases little benefit can be expected from the remedy.

We must not, however, discard *constitutional* treatment because it is not more direct and specific in its action. There are remedies which, by acting indirectly, aid especially by relieving congestion of the uterine mucous membrane, and are too valuable to be lost sight of in the treatment of uterine disease.

A patient with endometritis, who has, for instance, a coated tongue, constipated bowels, and impaired appetite, and loaded urine,—all indicating that her digestive organs are acting sluggishly,—would be benefited by appropriate general remedies. A dose of calomel, followed by some mild saline cathartic, while it would improve her digestion, would perhaps do more indirectly to relieve congestion of the pelvic organs than any other remedial means at your command. This you can clearly comprehend, when you remember the direct connection of the portal and pelvic veins. Where the portal vessels are engorged, there is necessarily a sluggish condition of abdominal circulation, which sooner or later communicates itself to the pelvic organs.

Now, in such cases, we must secure, if possible, freedom of abdominal circulation. Without it our best directed efforts are often unavailing. No remedy accomplishes this better than occasional mercurial cathartics, followed by salines. I desire to press this point, because the enemies of scientific medicine have created, in my judgment, an unfounded prejudice against the use of mercury, which is liable to deter the physician from using one of the most valuable remedies which we possess for the relief of abdominal and pelvic congestion.

In other cases, where there is marked debility, a rapid, thready pulse, and much nervous restlessness, you may, to some extent, control the profuse menstruation by the use of digitalis, aromatic sulphuric acid, with or without small doses of morphine. Beyond these means I have not much faith in constitutional medication for the arrest of hemorrhage, not even in the much vaunted ergot.

During the interval between the catamenial periods, every means should be employed to improve the general health and strength of the patient, such as exercise in the open air, followed by periods of rest in the horizontal posture; or as Dr. Wright has tersely expressed it: "exercise should be enjoined, exertion forbidden."

Good nutritious food, with tonics suitable to each individual case, should also be prescribed. The blood is apt to become impoverished in all this class of cases; hence ferruginous tonics are called for; and you will find that judgment and skill are required in adapting these remedies to the capricious stomachs of your patients. The more agreeable chalybeates usually answer best, such as *ferri pyrophosphate* or *ferri et potassæ tartrat.* And you should always see to it that your patients do not suffer from constipated bowels while taking iron.

From the fact that uterine disease tends greatly to debilitate the nervous system, you will have to give special attention to that, and you ought always to employ the more restorative nerve tonics, rather than anodynes, because this class of people, above all others, are exceedingly prone to acquire the habit of opium-eating. The possibility of this result should never be lost sight of when prescribing for this class of cases.

The comp. syr. of the phosphates, or the phosphates given in connection with cod-liver oil or the syr. of the iodide of iron, taken after meals, will answer well in many cases. They are food for the nervous system. I must not fail to mention also strychnia, iron, and *arsenic*. These are among our most valued remedies in sustaining the flagging powers of exhausted nerve energy.

We have other valued resources in a class of *nervines*. Uncomfortable symptoms of a nervous character, known by the vague terms of "nervous irritability," "nervous hyperæsthesia," etc., are often relieved by the valerianate of ammonia, or the bromide of potassium, of ammonium, or of lithium. Of drugs employed to relieve excessive irritability of the nervous system, perhaps the bromides are our most reliable agents. I have used them with most satisfactory results. We should never lose sight of the fact, however, that their continued use tends to anæmia, and that in some cases of anæmia of the nerve centres they depress the nervous system and intensify the nervous phenomena.

To sum up the *constitutional* treatment of uterine disease, I may briefly state, that the general principles which govern us in the management of the various forms of *general debility* apply in the case under consideration.

Bear in mind the important therapeutic fact, that the treatment which most improves the general nutrition and increases the supply of rich, well oxidized blood, will do most towards improving any local disease. Before leaving this subject I must call your attention especially to the use of *quinine* in the treatment of uterine disease.

Those of you who practise in malarial regions will make but poor headway in the treatment of uterine disease without this most valuable agent. I have re-

peatedly observed cases of uterine disease, when menorrhagia and amenorrhœa were prominent symptoms, which had resisted the usual treatment, improve very markedly under the free use of quinine. I have no words of explanation to offer as to its mode of action, but of the therapeutic fact there can be no doubt.

Local treatment should be employed with the view of accomplishing two objects: *first*, to remove the disease; and, *second*, to restore the organ to its normal condition. You will at once, perhaps, infer that, if we attain the first object, the second will follow as a natural consequence; but it may or may not, according to the character of the treatment employed. I am satisfied that, in times past, and even at present, much of the treatment of uterine disease, while it arrests the inflammatory trouble, proves so destructive to the normal structure of the organ as to render the last condition of the patient worse than the first.

Local treatment should be employed principally, if not wholly, during the interval between the menstrual periods. We are rarely called upon to make local applications during the catamenial flow.

If there is only a slight excess of the menses we are not called upon to do more than keep the patient at rest. Indeed, in cases of endometritis, free menstruation is undoubtedly conservative. It is a natural effort to relieve the local congestion; and, if the general strength of the patient does not greatly suffer, we need not try to arrest the flow.

We should rather endeavor to remove the *cause* of the profuse discharge before the recurrence of the next period.

Regarding local treatment there is perplexing diversity of opinion, perhaps more than in any other department of medicine.

Disregarding much of the confusing and contradictory literature of the subject, I shall endeavor to fix your attention upon a few points which I regard as well established and likely to be of service to you hereafter.

The three important questions which come up for our consideration on this subject are: 1st, to what part of the diseased organ shall we make our applications? 2d, what curative agents shall we employ? and, 3d, how shall we apply them? If you turn to your text-books or the current literature of the profession in search of an answer to the *first* question, you will find the greatest diversity of opinions and will likely be most thoroughly perplexed. The pioneer gynæcologists of Europe, such as *M. Gendrin*, *M. Jobert de Lamballe*, *Bennet*, and *Simpson*, rarely, if ever, made applications beyond the os internum; believing that uterine inflammation could be cured by treating the *cervix* and *cervical canal*.

On the other hand, we find that *Aran*, *Scanzoni* and *Gantillon*; and, in our own country, *Dr. Henry Miller* (who was, by the way, the first to employ intra-uterine medication in this country), *Kammerer*, *Nott*, *Paulee*, and many others, rely, to a very great extent, on intra-uterine applications for the relief of endometritis and uterine catarrh.

Many more names might be mentioned to show the want of harmony among physicians on this point; but no useful knowledge could be gained thereby.

The only point of interest which we can learn from this review is, that, so far as I can judge, intra-uterine medication is more extensively employed now than formerly. Believing, then, that time tends to drift us to correct therapeutics, we may infer that local applications to part or to the entire lining membrane of the uterine cavity are often necessary, if not indispensable in treating endometritis.

In seeking an answer to our *second* question, we encounter a variety of medicinal agents, ranging from the actual cautery to the blandest anodyne lotion. Reviewing the nature and effects of the various remedies used in the treatment of uterine disease, we could in no way be guided thereby in making a selection.

Bearing in mind, however, the second object to be gained, viz.: to restore the organ to health, and leave the uterus *uninjured in structure*, we are bound at once to reject all the more powerful and destructive agents, such as strong nitric and chromic acid, caustic potash, the actual cautery, etc., etc. All these have been used, and are now, though less extensively, I trust, than formerly, in the treatment of simple chronic endometritis, or hyperæmia of the mucous membrane of the cavity of the uterus.

Leaving out of account the value of these potent agents in the treatment of *malignant* diseases of the uterus, I desire to be distinctly understood as opposed to their use in the treatment of *benign* uterine disease. I readily admit that inflammation of a mucous membrane can and may have been "cured," as the expression is, by such means. I cannot doubt but that a surgeon can "cure" a gleet by burning out the whole mucous membrane of the urethra with caustics or fuming nitric acid! There would be nothing left, in time, but a cicatrix which could not of course secrete the glairy mucous discharge of gleet; but most men, I am inclined to think, would prefer the disease to such treatment with such results.

The oculist could "cure" a chronic conjunctivitis in the same way; but I fear the eye would hardly be presentable afterwards, and it would surely fail to perform its normal function. Still, there are those who treat the same affections of the mucous membrane of the *uterus* with these destructive agents, and the results which follow can be easily imagined.

It may be argued, I am aware, that *strong* caustics are being used less and less by the profession in the treatment of uterine disease; and I am glad to believe that such is the case. The nitric acid and chromic acid and other caustics are being laid aside, but only, I fear, to give place, in many cases, to a new, but none the less destructive, agent;—I allude to *galvano-cautery*.

This, as you know, is becoming the "fashionable" caustic or cautery of the day; and I trust I most thoroughly appreciate its value in the treatment of *malignant* disease, when the destruction of tissue is called for. But in the treatment of benign inflammation it cannot fail to work a great and uncalled for destruction, like the other agents used in the past. I can see no argument for or against it that may not be urged in the case of the caustics mentioned.

In the management of uterine disease, we may be guided by some of the generally accepted rules laid down by surgeons for the treatment of inflammation generally, such as: place the diseased organ at *rest*; quiet irritation by sedatives; and relieve the congestion by depletion, astringents, and alteratives. To accomplish these objects we must employ all the improved means brought forward by modern investigation, changing and adapting them so as to meet the peculiarities of each case. First, then, secure rest by having the patient abstain from long-continued standing or walking, and from the excitement of coitus.

If the uterus is displaced, replace it, and sustain it in its normal position by the support of a well-fitting pessary.

To relieve pain and quiet the irritation, a vaginal or rectal suppository (made of extract of belladonna

and sulphate of morphia, one-eighth to one-half a grain of each with cocoa butter) used at bed-time, will often give great relief. Belladonna or stramonium, without opium, will answer in many cases.

I desire to call your attention specially to the next agent, namely, *depletion*, because I regard it as incomparably the most potent agent we possess. In making this statement, I am aware that I encounter much professional prejudice. Blood-letting has ceased to be the fashion of the day. The lancet is condemned as a "little instrument of mighty mischief;" few of the younger portion of the profession have ever seen a patient bled. Local depletion held its own some time after general venesection was, to a great extent, abandoned. But even this has gradually given way to the popular prejudice of the day. Nevertheless, the fact in surgical therapeutics remains true as ever, that the removal of blood directly from the vessels of an inflamed or congested organ is the most potent means of relief we possess, and in nothing do we see its virtues so signally displayed as in the treatment of *uterine disease*. Upon this point I speak with great confidence, for my observation has been large and varied.

Depletion is accomplished in various ways according to the effect desired. When menstruation is scanty and irregular, a leech applied to the cervix in a day or two after the flow has ceased will frequently relieve the engorgement, and, in time, establish the normal uterine function. But leeching should seldom be practiced more than once a month, and that soon after the menstrual flow. This should be followed by scarification at intervals of six or seven days throughout the interval between the menstrual periods. A number of very superficial incisions, made around the external or internal os, or both, will generally answer the purpose.

But when there is much swelling of the cervix there is no substitute for leeching or puncturing, as I shall describe hereafter. When menorrhagia is present, of course leeching is not to be thought of. Free scarification will then answer better, and may be resorted to soon after the flow stops. The incisions, in such cases, should be made from within the os internum outward. This will, in some cases, prevent a recurrence of the menorrhagia. If it fail to do so, it should not be repeated. *Persistent menorrhagia* indicates the existence of certain conditions of the mucous membrane of the uterine cavity which will not be relieved by depletion. In such cases dilatation with sponge tents becomes necessary. A succession of graduated sponge or sea-tangle tents must be employed, and in case of any undue irritation occurring in the uterus while this process is going on, the treatment should be interrupted till it passes off. The free distention of the cervix, thus obtained, enables us to get more exact knowledge regarding the state of the uterine cavity, and prepares the way for the use of astringents, or such other local treatment as may be required. The pressure of the tent is sufficient, in some cases, to reduce the swelling of the mucous membrane and lessen the circulation of the vessels disposed to bleed. Dilatation often reveals the fact that the mucous membrane is hypertrophied wholly, or in patches, looking as if exuberant granulations were sprouting up. A distended gland is occasionally found which looks like a miniature polypus. This condition is most promptly disposed of by the uterine *curette*. The instrument is carried up to the fundus and then carefully withdrawn, pressure being made at the same time so that the cutting edge shall hug or scrape the mucous membrane. This manœuvre is repeated until all irregularities of the mucous surface are removed. The *curette* which I prefer is that represented in the accompanying cut. The two sides of the triangle are rounded, so as to prevent the cutting portion at the upper end from going too deep. Such an instrument will only take hold of irregular elevations, and will slip over the smooth mucous membrane without doing any harm. Some pain and tenderness may be expected to follow this operation, but will require no treatment except a short period of rest. When the operation has been well performed, it seldom needs to be repeated. The menorrhagia due to the conditions just alluded to is promptly relieved by this mode of treatment. So far as my observation extends, the operation, if carefully made, is not attended with any great danger. No marked constitutional disturbance occurred in any of my cases, and the slight uterine tenderness soon disappeared. Few patients, however, require this kind of treatment; the majority get well under the use of astringents and alteratives. This brings us to the consideration of *intra-uterine medication*; and as this kind of treatment involves great danger at times, we must carefully note the conditions which are most conducive to safety.

The principal rules for our guidance are:—That intra-uterine applications should not be used until we have thoroughly tried and failed with other means;

The uterus should be in or near its normal position;

The cervix uteri should be sufficiently dilated to allow the fluid to escape from the cavity of the body;

Such a syringe should be used as will aid in effecting a free reflux or regurgitation;

The injection should be made *very slowly*, because the uterus will not tolerate rapid distention;

The blandest fluid ought to be tried first, in order to test the tolerance of the uterus;

And no agent whatever should be used which might *permanently injure the mucous membrane*.

In some cases the canal of the cervix is sufficiently open to permit the application of intra-uterine treatment; but it is often necessary to produce dilatation as a preliminary step. You will find the sea-tangle tent very useful for this purpose; better, I think, than the sponge. It dilates more slowly, causes less pain, and does not produce so much irritation of the mucous membrane as the sponge tent. Drs. Peaslee and Kammerer employ bougies for dilatation; but I have not been fortunate in using them, and cannot, therefore, recommend them. In order to carry the bougie through the canal some force is necessary, and to counteract this the uterus must be firmly held with forceps or tenaculum; and, with your pushing and pulling, you inevitably cause pain and bruise the tissues—at least that is my experience. The sea-tangle is easier and safer, and I therefore prefer it.

Now, having opened a free passage to the uterine cavity and back again, we have to consider what medication we shall carry into it, and how? Well, we may inject the chosen medicament by some form of syringe, ordinary or extraordinary; or we may ingest the same by means of a swab, hair-pencil, probang, Dr. Miller's lint pledgets, or some such vehicle. You will find injection the most convenient, the most thorough, and, if you are careless, the most *dangerous*. The danger can be avoided in great measure, by the observance of the rules already given. To facilitate the injection and subsequent outflow, many devices have been offered to the profession. Gantillon uses an ordinary syringe, having the tube pierced with holes directed backward towards the operator. Dr. Nott, of New York, has constructed a catheter, which I believe is very good. I have found the syringe used by me to answer nicely. The tube in the centre

through which the fluid is injected is very small;—parallel and external to it, are four grooves which afford an ample outflow.

With this instrument the uterine cavity can be injected—in most cases requiring it—very thoroughly and without causing severe pain.

We are indebted to Dr. Peaslee for some valuable hints guiding us to safe methods of intra-uterine medication. He shows that the tolerance of the uterus is quite variable, and that careful trials of injections or ingesta of the least irritating character ought to be made before resort is had to any powerful or irritating application. He would have us begin with salt and water as being most like the normal secretion of the mucus membranes. When that is well borne, some astringents may be tried. Previously, however, the canal of the cervix must be cleansed of its secretion. Some authors direct that the cavity of the body be cleansed also, but I am sure that, as a rule, you will find but little secretion there. The tenacious secretion, to say the least, is limited principally to the canal of the cervix. The agents to be used vary according to the conditions. In menorrhagia, when we desire to arrest the bleeding, I prefer the salts of iron,—the subsulphate being the best. The *Liquor Ferri Subsulphatis*, either of full strength or diluted, is a favorite with many. I generally use the powder, rubbed up with simple cerate and olive oil, after this formula:—

℞.

Ferri Subsulph Ex sicc.....ʒj.
Cerat Simplic.,
Olei Olivæ.....āā ʒss.
M.

About one-third of this, or much less, according to the size of the cavity, may be used at a time. An ordinary urethral or uterine syringe will answer every purpose, care being taken to inject as slowly as possible. Iodine may be employed in the same way, using the "iodine ointment" sufficiently diluted with oil to make it flow through the syringe. I claim for these applications that they are less liable than more limpid fluids to enter the oviducts; and, as they act slowly, they do not produce shock or violent uterine colic. Pain is usually set up after a time; but not of that alarming character which is sometimes observed to follow injections of caustic fluids.

When the object is simply to relieve hyperæmia, or subacute inflammation, the mildest astringents or alteratives will answer all the requirements. A saturated solution of the chlorate of potash, or ten grains of borax to the ounce of water, may be used with the reflux syringe. Weaker solutions than these will prove beneficial, and will be borne when the stronger might cause pain.

If the reflux is perfect, and no distress is experienced by the patient, the injections may be continued for three or four minutes at each application. Nitrate of silver, sulphate of copper, sulphate of zinc, and chloride of zinc may also be used; but I urge you not to employ more than a grain and a half of either of these to an ounce of water. If you begin with a stronger solution you run a good deal of risk; whereas with a mild preparation you can feel your way, and continue the application till you get the desired effect, or until you make sure that you have thoroughly bathed the entire mucous membrane. Whenever any of the stronger preparations are called for, I prefer to use them, as before stated, in the form of unguents.

You will usually succeed in relieving hyperæmic and inflammatory diseases of the body of the uterus by some form of the treatment already indicated; but troubles in the cervical walls will be more incorrigible. Long after the establishment of regular and normal menstruation, and the disappearance of all the signs and symptoms of disease in the cavity of the body, you will have to continue waging battle with the hyperæmia of the cervical mucous membrane, the consequent leucorrhœa. To overcome this, scarification, as already described, should be practised once a week. If there is much swelling and congestion of the cervical walls, a few punctures made around the os with the point of the scarificator will answer a very good purpose. This practice is highly commended by Dr. M. S. Buttles, of New York, Dr. John Scott, of San Francisco, and others. I think it holds an intermediate position between leeching and scarification of the mucous membrane; it gives us more depletion than the one, and less than the other.

When all evidence of congestion has disappeared, and nothing of the disease remains except hyper-secretion or leucorrhœa, then some special application to the cervical mucous membrane is indicated. Of the many agents that have been tried for this purpose, the nitrate of silver has stood the test of time better than any other. My observations, while acting as assistant to Prof. Chapman some years since, fully impressed me with the value of this article. He applied it in solution (30 to 40 grains to ʒj.) about once a week. I am satisfied, however, that a weaker solution, say 15 or 20 grains to the oz., will answer just as well. Sulphate of zinc in a solution of 2–4 grs. to the oz. is also useful. Many other articles may be used, such as tr. iodine, tannin, sulphate of copper, sulphate of iron, acetate of lead, carbolic acid, etc.

Before using any of these applications to the cervical canal, care must be taken to remove the tenacious secretion, so that the medical agent may come in direct contact with the mucous membrane. If this is neglected, the medicine used may be neutralized by the secretion, and do very little, if any, good. The reflex catheter, already described, will accomplish this; carry the instrument up to the internal os, and inject warm water freely; this will wash out the secretion, and leave the mucous surface clean and ready for the application.

Various modes of making applications to the cervical canal are practised. Wrapping a piece of new cotton around the point of a probe or piece of whalebone, a swab is thus formed, which, being dipped in the agent to be used, is carried along the canal. Brushes of various forms have also been used. The objection to these instruments is, that you cannot carry enough of the solution into the canal with the swab or brush at *one application*, and, if you use it again and again, you are likely to cause irritation of the mucous membrane. They also get soiled, and do not answer for more than one or two applications. I much prefer a glass rod of small size well rounded at one end, and curved like a uterine sound. To the other end a small rubber bulb is attached. By compressing the bulb or little bag the air is exhausted, and by dipping the open end into the solution to be used, enough will be drawn up for an application. The tube is then carried up to the internal os, and by pressing on the rubber bulb the fluid is gently injected into the canal.

I usually keep a number of these glass tubes on hand, bent at various curves to suit different cases. These tubes answer perfectly well, and the only objection that can be raised against them is that they are easily broken; but they cost very little, and can be replaced more conveniently than a swab or brush.

These applications should be made about once a

week, care being taken not to employ this kind of treatment immediately *before* the time for menstruation.

It is well to suspend all local application for four or five days before menstruation, lest that function might be deranged by the treatment. On the second or third day after the menstrual flow stops, the treatment should be resumed.

After all evidence of disease has gone, the patient should still be kept under observation for a time.

About a week after each of the two or three succeeding menstrual periods, an examination should be made, and if any return of leucorrhœa is observed, an application should be employed.

During this treatment of the uterus some attention to the vagina and vaginal portion of the cervix may be necessary. When vaginitis accompanies the uterine disease, it should be treated according to the directions given on a former occasion.

The mucous membrane around the os uteri, when denuded of its epithelium and presenting an appearance resembling a granulating ulcer, should be managed similarly to the lining membrane of the uterine cavity. The papillæ of the mucous membrane around the os should be scarified thoroughly once a week until the hyperæsthesia is relieved. Daily injections of water in large quantity is very efficacious in all such cases. Not only will it relieve the congestion and irritability of the mucous membrane with which it comes in contact, but it will, if used *very hot*, produce the same effect on the uterus, and indeed on the whole pelvic contents.

Hot water, when persistently applied, is one of the most valuable antiphlogistics which we possess, and may be used with marked advantage, not only in the uterine disease now under consideration, but in all other affections of an inflammatory or hyperæmic character. The best result is gained from its use in hospital, when it is used by trained nurses; but by instructing your private patients how to use it, they can accomplish much by it.

Place the patient in a horizontal position, with the pelvis slightly elevated; put a bedpan under her to receive the water as it flows away; then, with a Davidson's syringe, inject gradually a large quantity, say a gallon or two at a time. I direct my patients to begin with lukewarm water and increase the temperature every day until they get it as hot as they can comfortably bear it. I find that, in time, they will use a temperature of 108 to 110°, and experience great relief from pelvic symptoms.

It is claimed by some, who use water in this way, that it first produces an increase in the congestion of the vagina and the vaginal portion of the cervix; but, after continuing the applications for a time, the blood-vessels contract, the circulation in the part is increased in activity, and hence the hyperæmia is relieved.

Water alone is all that is necessary as an injection in most cases of endometritis: but when there is vaginitis, the water should be medicated. Among the many agents recommended you will find borax will answer more generally than any other— ℥ j.— ℥ iij. to a quart of water answers very well. When there is much relaxation of the vagina and mucous membrane of the lips of the cervix, a solution of alum should be used occasionally. Dr. J. Marion Sims uses, for a similar purpose, a roll of cotton saturated with glycerine, which is introduced into the vagina and changed daily. This answers admirably in many cases; the cotton keeps the inflamed surfaces apart, and the glycerine causes free secretion, or possibly exosmosis from the mucous membrane, which, by that form of depletion, relieves the congestion. The same authority commends the use of a concentrated extract of *pinus canadensis*, to be used in the same way as the cotton and glycerine. I have had no experience with this agent, and can therefore say nothing about it.

There are many points in the treatment of uterine disease which yet remain to be considered; such as the local use of iodine, mercury, cupping, blistering the cervix, electricity, etc.; but these agents are of most value in the management of other forms of uterine disease, and may be omitted in the consideration of the therapeutics of *endometritis*.

Newark Medical Association, N. J.—This Association has elected the following officers for 1873: *President*, Charles Young, M.D.; *Vice-President*, R. M. Sutphen, M.D.; *Secretary*, Aaron K. Baldwin, M.D.; *Treasurer*, J. A. Cross, M.D.

Graefe.—Appleton's Journal is responsible for the following: The late Dr. von Graefe, the renowned German oculist, leaves in his posthumous papers the remarkable admission that he frequently performed dangerous operations when he despaired of success, merely to gratify the patients and their relatives.

New Lying-in Hospital.—On the 1st of January, 1873, a new Lying-in Hospital was established at the West End, Boston, Mass. The medical officers are Drs. Francis Minot, John P. Reynolds, and Chas. E. Buckingham, *Consulting Physicians*; Drs. Henry Tuck and Wm. L. Richardson, *Visiting Physicians*.

Reports of Hospitals.

BELLEVUE HOSPITAL, N. Y.

NOTES OF PRACTICE, AND PECULIARITIES OF TREATMENT.

The following items are not without interest to such as are debarred the opportunity of visiting our metropolitan hospitals, and informing themselves of the small matters, the knowledge of which is often the turning-point in the treatment of the most important cases.

In the present article Bellevue Hospital is selected as the institution to furnish material for notes; at a future time, and as opportunity offers, we shall give the results of our visits to similar charities in this city, and do our best to give everything of practical value which may offer itself.

MODIFICATION OF THE PLASTER-OF-PARIS SPLINT.

There has been recently devised a modification of the plaster-of-Paris splint. It consists in laying strips of tin or wire gauze, about three-fourths of an inch in width, lengthwise of the limb. The flexibility of these strips is such that they readily accommodate themselves to any unevenness upon the surface, and yet strongly resist any lateral displacement. The advantages derived from these strips are, that an equally firm splint is obtained as when the plaster alone is used, and a very much lighter one; and that the morals of the juniors are so much the less liable to be perverted by not being obliged to cut through so heavy a covering when it is desirable to remove the fixed apparatus.

SKIN GRAFTING.

This has come to be an ordinary method of restoring cutaneous covering to extensive ulcerating surfaces. In transplanting the little grafts, it is said to

be necessary that they should be cut of such size and thickness as to prevent their turning up at the edges. To prevent the eversion of the edges the pieces are cut small and thin, embracing scarcely more than the epithelium, and very often the most successful grafts are those which are removed from the healthy flesh without producing hemorrhage.

ULCERS.

The old, chronic ulcers, with indurated edges, are sometimes immensely benefited by making numerous free incisions through their indurated tissues, even down to and through the periosteum, if that structure is thickened. This is followed by firm strapping with adhesive plaster. The result is a reduction of the congestion which has long existed in the parts, and the production of an alterative action in the tissues, which renders them more healthy. Some wonderfully obstinate cases are cured by this method of treatment.

DROP WRIST.

A case of "drop wrist" has been under treatment by the use of galvanism and hypodermic injections of strychnia—$\frac{1}{75}$ of a grain of the sulphate twice a day. This patient had received various kinds of treatment before his admission to the hospital, but without benefit. The ordinary iodide of potassium treatment has given him no relief whatever, but from the date of the commencement of the treatment by the use of the strychnia and galvanism, he began to improve rapidly.

TAPPING FOR THE RELIEF OF TYMPANITES.

A poor fellow was suffering with his abdomen immensely distended by gaseous accumulation. It was proposed in his case to tap the colon with a fine needle, convenient for the purpose, and thus permit the escape of the gas. The needle of the ordinary hypodermic syringe could be easily used for this purpose. The operation is not regarded as a new one, and is not disapproved of by the visiting physician. It is said to be simple in its nature, easily performed, and unattended by serious results.

TREATMENT OF PNEUMONIA.

A large number of cases of pneumonia this season are complicated by bronchitis. This complication is quite uniform, and with it is associated an alarming fatality.

The treatment which cases of pneumonia receive in this hospital varies somewhat. With some, the favorite method of treatment is by the use of quinine from the beginning, in 10 gr. doses three times a day.

The particular idea entertained in relation to its effect is, that it is anti-cell-producing that it, diminishes the amount of cell material effused into the air-vesicles in the progress of the disease.

Some cases receive no quinine at all, and have whiskey altogether. One man, who had been brought in with the bronchial complication, was in a condition that demanded the immediate and free use of stimulants, and under their administration he was getting well.

The general principles of treatment, however, are to reduce the pulse and temperature and give tonics and good diet. To reduce the pulse, aconite is more commonly used than veratrum viride. Fleming's tincture is a favorite preparation. If the temperature rises to 102° or 103° means may be employed to reduce it. In many cases simple sponging is sufficient, and gives the patient much relief.

Quinine is believed to have the power of reducing the temperature of a fever, and is used with this end in view, as well as the one already mentioned. When given, it is in full doses, whichever may be the object. The oil-silk jacket is not much resorted to, being of doubtful efficacy.

SCIATICA.

Some cases of this disease which had resisted a variety of treatment—such a variety as a patient is liable to receive who has been afflicted with the malady for three or four months, and gone from one doctor to another—were cured, *almost at once*, by the hypodermic injection of morphine over the seat of pain, plunging the needle deep into the tissues, perhaps to the depth of one or one and a half inches.

TREATMENT OF ACUTE ARTICULAR RHEUMATISM.

The alkaline treatment is the one usually employed in the treatment of this affection. Local applications to the joints are not much employed. Sometimes the joints are wrapped up in cotton; sometimes nitrate of potassa is sprinkled into the cotton before it is applied; and sometimes anodyne lotions are employed. The patients receive opium sufficient to allay pain and secure rest.

The presence of chorea as an intercurrent affection in cases of rheumatism, was noticed in two cases.

The opinion has been expressed by some distinguished clinical teachers and writers, that there is a pathological connection between the two diseases; and one writer has published a monogram in which he produces a large number of cases in support of his theory. Some of the prominent clinical instructors here advocate this doctrine, while others regard it as a view which can hardly be sustained.

PLEURISY WITH EFFUSION.

These cases are treated regularly by the use of diuretics. The use of counter-irritation seems to be regarded either as conditional or non-essential. While the inflammatory action exists in its subacute form, blisters are recommended to subdue it. Some patients are up about the wards who have a pleural cavity filled with fluid, are receiving their diuretics, good diet, and that is all.

Some of these cases amend by the use of diuretics alone, some by the addition of counter-irritation, and some only by the addition of paracentesis. With some men this is *the* plan for removal of the fluid. There is one thing to be said concerning this operation, which is practical; that is, when a pleural cavity is very full of fluid, it is very beneficial in many instances to tap at the *beginning*, and remove a portion of the fluid, for by so doing the absorbent vessels may be so relieved from pressure that they will go to work under the influence of diuretics and accomplish all that may be desired; whereas, without this operation, they would have been able to accomplish but very little. In one patient five pints of fluid were drawn off, when he was placed upon acetate of potassa and the use of counter-irritation in the shape of blisters, and there was soon a manifest improvement in his case. When he was first admitted his left chest was completely filled with fluid.

A very fashionable method of removing fluid from the pleural cavity, and other closed cavities, at the present time, is by the use of what is known as the aspirateur (Dieulafoy's).

The briefest definition of the instrument which I have heard is that "it is an instrument acting upon nearly the same principle as the stomach-pump, and costing sixty dollars."

This instrument was very successfully used a few days since for the removal of the urine from the bladder of a patient who was suffering from retention on account of a traumatic stricture.

A fine trocar was plunged into the bladder about one inch, the bladder being distended above the pubes in the median line, the aspirateur attached, and twenty ounces of clear water drawn off, to the great relief of the patient. This operation was repeated, and thus the patient was placed in a much more favorable condition for the subsequent operation for the relief of the stricture, than he otherwise could have been had he not been relieved in this manner. The operation for removing fluids from such closed cavities are nothing very new, but the aspirateur is said to be a most excellent assistant in carrying out the operation.

NIGHT SWEATS OF PHTHISIS.

For the relief of this exceedingly troublesome symptom in this disease, a comparatively new remedy is being used somewhat.

It is the sulphate of atropia. Some of the patients are taking $\frac{1}{60}$ of a grain in solution *ter in die*; some are taking $\frac{1}{100}$ of a grain at bed-time, and all are giving very good results.

The success in this direction has already been sufficient to entitle it to a trial at least.

A very excellent plan of managing these night sweats is also practised, which consists in sponging the patient with hot water, as hot as they can comfortably bear.

If a patient is found sweating profusely in the night, take him out of bed, sponge him thoroughly with hot water, wipe him dry, replace his flannels, and put him back to bed.

Sometimes a single sponging will arrest the sweating for two or three days.

TAPE-WORM.

Many remedies have been vaunted as being exceedingly efficacious in ejecting this most troublesome partner. Without doubt the success attending the administration of any remedy depends very much upon the method in which it is administered. A patient here has been treated in the following manner with success. The remedy used was the Male Fern.

℞. Liquid Ext. Male Fern,
Syr. Gum Arabic, āā
M.

The patient took nothing for supper, and in the evening took a full dose of castor-oil. In the morning she took no breakfast, but took a dessert-spoonful of the mixture, and repeated it every four hours until an effect was produced upon the bowels, or the stomach ceased to tolerate it.

In general, the remedies for the removal of this parasite are to be taken fasting; and doubtless in many cases success has been denied on account of a want of specific directions in regard to manner of employing the remedy employed.

NITRATE OF AMYL.

This is a remedy which is used somewhat for the relief of dyspnœa. An old lady, the subject of emphysema and chronic bronchitis, has her vial of amyl upon her stand, and when she feels her attacks of dyspnœa coming on, she allays them very readily by dropping a few drops upon some lint—5 is the usual number directed—and inhaling it.

It is of benefit in the dyspnœa of bronchial asthma, the dyspnœa of that peculiar grouping of symptoms which go to make up angina pectoris, and dyspnœa form any similar cause.

GALACTO-POETICA.

The following mixture was administered t. i. d. to promote the secretion of milk:

℞ Tr. Ferri Muriatis gtts. x
Potassæ chlorat. grs. x.
M.

This prescription was witten for a patient who had been suffering from pelvic cellulitis, accompanied by a marked diminution in the quantity of milk secreted.

Progress of Medical Science.

OBESITY A CAUSE OF DISEASES OF THE FEMALE SEXUAL ORGANS.—According to H. Kirsch, of Prague (*Centralbl. f. d. Med. Wis.*, No. 34), diseases of the sexual organs in women are not unfrequently dependent upon the presence of an abnormal amount of adipose tissue. He bases his assertion upon the examination of 215 stout women. Of these, irregularity in the menstrual function presented itself in 208; and of these, 146 had leucorrhœa, 116 complained of scanty menstruation, and 56 of chronic metritis; 47 suffered from hysteria, 48 were sterile; 39 exhibited anteflexion and anteversion of the womb, and 11 retroflexion. The writer avers that most of these affections improve without further treatment when the obesity has been made to disappear. A course of diet somewhat like that advocated by Banting, combined with a moderate use of the waters of Carlsbad and Marienbad, is recommended.

THE LYMPHATICS OF THE SKIN.—Dr Neumann, of Vienna, has been making a careful study of the lymphatic system in the skin, and has arrived at the following conclusions:—

1. The lymphatics of the skin may be regarded as a system of closed tubes, whose walls are independent of the surrounding tissues, and are lined internally with flattened epithelium; these tubes have no orifices whatever, and consequently do not communicate with the so-called serous canaliculi, or any other similar network in the interstices; no openings exist between the epithelial cells, not even when the vessels have undergone pathological changes.

2. Of the blood and lymphatic capillaries, the former are always nearest the surface of the skin; in the deeper parts of the cutis, the branches and networks of each system intercalate with one another in an intricate way. No invagination of one lymphatic vessel within another was observed.

3. In the two series of lymphatic networks that exist in the cutis, the deeper one is made up of broader and stouter vessels. No valves or stomata are found in this situation, though in the subcutaneous tissues they occur occasionally. Lymphatic tubes or loops are supplied to the papillæ.

4. The sweat-glands, hair-roots, and follicles are furnished with lymphatic capillaries. The fat lobules are similarly provided.

5. The distribution of the lymphatics varies in the different parts of the body. They are most numerous in the labia majora, scrotum, palms of the hands and soles of the feet.

6. Sometimes dilatation of these vessels is observed in parts that have undergone pathological change.

7. In ulcerative processes, when lymphatics are destroyed, they may be regenerated; when observed in cicatricial tissue, they are diminished in size.

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

THE ALUMNI ASSOCIATIONS, AND THEIR INFLUENCES FOR GOOD.

It is only within the past few years that the alumni of our different medical colleges have claimed for themselves any existence in fact. From originally small gatherings, these organizations have so increased that active members are scattered all over the country, and will travel scores of miles to attend the stated reunions. There are many reasons why we should congratulate ourselves on such a state of things. Aside from the good which these meetings do to the members, individually and collectively, in affording opportunities for social enjoyment and professional encouragement, there is much more that can be done for the colleges, and through them for the educational interests of the profession at large. It must not be denied that the alumni associations are becoming foci of immense power and influence; that they are capable, by the very circumstances of their formation, of creating a healthy professional sentiment for reform which could not be done by any other means. They can in reality be the powers behind the throne, and, if they make proper use of their opportunities, can insist upon changes in the schools, which in the end will redound to the credit of all interested parties. The college must be poor indeed which, after an existence of a score of years, cannot count among its graduates men who have by sheer diligence risen to the front ranks of their profession—men who have obtained for themselves positions which, if their former teachers care not to envy, they must at least respect. These successful men are earnest in their endeavors to lessen those difficulties in their successors which their own hard-earned experiences have verified—they are actuated with the commendable disposition to prepare the future generations of medical men to combat these obstacles more successfully. In such a work they can afford to be independent of mere selfish considerations, with perhaps the single exception of a jealous pride in the success of their alma mater.

The alumni should always have a special influence with their alma mater on this very account. They must be presumed to be the best friends to their own college. There is no element but partiality towards an institution from which they have received their diplomas, and all the suggestions for reform should be so considered by the faculties. If the associations are outspoken in their convictions as to what is right, their opinions should receive all the weight which this acknowledgment of friendship to the governing powers should entitle them.

Already we have had evidences of their influence with their respective teachers. On more than one occasion these very associations have taken up the discussion of matters pertaining to the colleges which even the faculties, from purely politic motives, did not dare to touch upon. They have borne the odium of adverse criticism with that independence which a conviction of being in the right alone can give, and have at last come off victorious, generously sharing the palm with a misguided but repentant faculty. Not only can the alumni of any institution step in at times to maintain a good name, but they are able and willing to increase the reputation and usefulness of these seats of learning. It is within their power to do for a college what it may in a pecuniary sense be incapable of doing for itself. In the shape of endowments, for instance, it can give a practical turn to the suggestions for reform in the shape of extra professorships, increased time for study, and the like, which assistance we can never expect to gain from any other quarter. In more than one of our colleges the initiative in this respect is already being taken with the promise of very gratifying results. This is one of the means to an end which gives us a pivot upon which to turn many of the time-worn suggestions of years past, and will give every one interested in educational matters a real and abiding interest in alumni associations. There are many other reasons why these organizations should prosper, but in our opinion this is the principal one, and if the alumni continue to take an interest in this matter the results cannot fail to satisfy the most sanguine. In order to smooth the way, however, we claim that the alumni association of each college should have a representation in the council: this is simple justice, and in many points of view the smallest possible compensation on the part of the faculties for the ultimate good to be attained.

The alumni associations of our colleges in this city are all in a prosperous condition—are, so to speak, permanent institutions. They number among their members some of the most influential men all over the country, men who know what is wanted in the way of reforms in medical education, and who are capable of

backing up their convictions in a practical manner. We cannot believe that when the proper time comes for initiating the necessary changes any one of them will be found in the background.

A RELIABLE METHOD OF INSURING PROFESSIONAL SUCCESS.

At the time when a large number of fresh doctors are thrown upon the tender mercies of the world, and are in need of advice to insure their professional success, we are reminded of the method adopted by the late Valentine Mott, and which he was in the habit of repeating to his class. He would always advise them first of all to work hard, to thoroughly ground themselves in their profession; but he would say that they needed something more:—"With all this, gentlemen, you require a little *judicious pushing* in the crowd. When I commenced practice I was as bad off as any of you will be; but I made up my mind, after waiting a reasonable time, to push a little. I first tried my finger, I then thrust in my hand; next I got one elbow in, next my head, next the other elbow, and finally my whole body"—"and," with the characteristic shrug of his shoulder, his peculiar smile, and the expressive twinkle of his eye, he would say, "that is the way, gentlemen, I managed to get practice." We have no doubt that if every graduate has as good a preparation for this elbowing process as Valentine Mott he will meet with a like success. The attempt "to paddle your own canoe" is not so successful in the abstract as the poet would lead us to believe; few if any can make any progress, in a professional sense at least, without occasionally relying upon a *skull*.

INSANITY IN THE FRENCH ARMY.

We referred in a previous issue to the alarming prevalence of insanity in the French army. This fact is worth recording. It is established in a recent number of the *Annales Medico-psychologiques*, that not only is this dreadful disease on the increase, but that it is becoming more intractable to treatment.

Three forms of insanity flourish in that army: From 20 to 30 years, mania takes possession of the young soldier, reduced to despair by a mode of living without occupation or issues; from 30 to 40, melancholy eats up those whose sense of honor is broken by base obediences; from 30 to 40, general paralysis seizes upon the strongest organizations. The nervous system of those who have been raised to high commands becomes as constricted, from head to foot, by the constant imbibition of alcohol, as anatomical pieces are in a solution of bichromate of potash. By this continuous saturation they first deaden the feeling of remorse when killing their fellow-countrymen, and they gradually come to lose the feeling of their own natural functions (gâteux).

The asylums of Charenton, of Auxerre, of Nevers, of Armentières, of St. Trond, of Bordeaux, etc., are the hiding-places of these broken instruments of an odious policy, and will soon open their doors to receive those who fire, and those who command the fire upon the would-be communists, in the plain of Satory.

The statistics of these unfortunates is full of interest. We have said that the proportion of insane is greater in the army than among the other classes. The proportion of the cures of insanity is less among the military than among the other classes. The proportion of the deaths from insanity is greater among the military than among the other classes. The proportion of the insane is greater among the officers than among the privates. The predominance of general paralysis over the other forms of insanity is infinitely greater among the officers than among the privates.

Insanity, too, presents in the army an intensity of character which one is not used to observe in other classes. The military life, in France at least, is prolific of insanity.

To sum up: insanity in the army has been constantly increasing in the number of its victims, in the acuteness of its symptoms, in the gravity of its prognosis, and in its fatal issues, from 1838 to 1872.

In regard to *its causes*, the author of the article "De la folie chez les militaires," in the *Annales Medico-psychologiques* of July, 1872, expresses himself thus:

As for the causes, they have not been noted with exactness. Therein he can be readily believed; for the French physician for the insane, who would note with exactness the causes of demoralization and *déraison* of the army, would soon be *noted* too; and upon the report of one of his confrères—of the one, for instance, who invented the "folie des grandeurs et des persécutions"—he would be quickly transferred from the parlors of the Direction to the cell of a lunatic.

Of the causes of the insanity of the French military everybody knows, but nobody dares to tell them, for the simple reason that they have too much in them to regret.

Every year the strongest young men are taken away from the family influence and submitted to an implacable police, which breeds defiance among themselves, hatred for their free fellow-citizens, and makes them considert he ultimatum of shooting working-men as a rich sport—the reward of tedious garrison servitude. If their young blood boils at these teachings and prospects, make them drink; if they long for a useful employment of their time, force, or skill, let them smoke; if they grow conscientious and reflective about the immorality of their calling, and entertain the idea, dear to the young soldier, that some day they may use their arms in support of their country, lead them to shoot the rabble, their very brothers and sisters.

Who could be surprised that the first *impression* produced by this moral *pression* marks the soldier for suicide by despair or by mania, with its multiform de-

lusions; that the second impression, produced by the turpitudes of garrison life, brings on melancholy and suicide by depression; and that the third impression, swifter than old age, nails the unfortunate (altogether a victim and a culprit) in a motionless stupor, at which an idiot could laugh.

After this exposition of the moral and medical condition of the French army by a physician saturated with Bicêtrian sympathies, one can represent the French working-man as a Prometheus, chained and eaten up, yet covering the world with the products of force and genius; and the military as a bottle of absinthe, whose neck comes out of red trousers.

Reviews and Notices of Books.

A Hand-Book of Post-Mortem Examinations and of Morbid Anatomy. By Francis Delafield, M.D., Curator to Bellevue Hospital, Pathologist to the Roosevelt Hospital, etc., etc. New York: William Wood & Co., 27 Great Jones Street. 1872.

We have long been in need of a manual for post-mortem examinations. Our information on this subject has always been scanty, and could only be gleaned with great pains from the bulky volumes of Medical Jurisprudence, or the abstruse treatises on Pathological Anatomy. For these obvious reasons they are not accessible to the ordinary practitioner, nor do they supply exactly what he needs.

In the book before us, the author has aimed to supply this deficiency. In doing so, however, he does not enter very deeply into the medico-legal aspects of such investigations, nor does he describe very minutely the microscopic appearances of diseases, but reserves both these subjects for larger books. The greater portion of the work is taken up with gross morbid appearances, and they are described in such clear and precise language that they may usually be recognized by any ordinary observer.

In the first forty pages we are told of the methods for making post-mortem examinations in adults and young children. The thoroughness and system which the author urges cannot be too highly prized. This is the only way by which we can hope to contribute anything to this department of science. We should be extremely cautious in forming conclusions as to the amount of disease that may produce death, for we have no definite standard of comparison. In one case a mild attack proves fatal, while in another a much severer one is borne with impunity. There are many cases, too, in which the most careful examination fails to find any assignable cause for death.

The following two hundred and fifty pages are devoted to the morbid anatomy of the organs. In the third division of the book, the author discusses the lesions of general diseases and the results to be observed in death from drowning and poisoning.

He concludes with a short description of the tumors. The pathology of wounds, fractures and dislocations, and subjects especially connected with surgical pathology, are omitted.

Among the chapters that are particularly good are those on the methods of examination and on the lungs and kidneys. They are all very valuable contributions to our present knowledge. The latter deserves special commendation for its precision and conciseness. The classification seems the most simple and rational of which we know.

The nomenclature of the tumors is about the same as was proposed by Virchow, and is the one now generally accepted. It is based on the character and relations of anatomical elements, and this is doubtless the only safe standard. Changes will be introduced from time to time as our knowledge of histology increases, but they will not seriously affect the present system.

We are glad to be able to recommend this book very highly. The author has brought to bear a large amount of experience and a mind that is logical and acute in its reasoning, and he has furnished us with a thoroughly safe companion for pathological study.

The facts that are regarded as definitely ascertained are stated with force and perspicuity, though sometimes with an unpleasant abruptness.

There is no effort made to cover our ignorance on subjects that are still obscure. In discussing doubtful points, the author usually gives the views held by leading pathologists, but he avoids mere theories as far as possible.

We are glad that New York has taken the lead in labors of this kind.

Contributions to the Pathology and Therapeutics of Variola. A Report made to the Berlin Medical Association, Nov. 13, 1872. By Dr. W. Zuelzer, Physician to the Charity Hospital, and Tutor in the University. (Separate sheets from the *Berlin Klin. Wochensch.*, 1872.)

This memoir is based upon the study of 326 cases of small-pox, received into the Charity Hospital between July, 1871, and April, 1872. It is principally devoted, however, to the cases of pure hemorrhagic variola, which represent the most severe grade of the disease, and are to be carefully distinguished from certain forms of the confluent pustular variety, in which slight hemorrhages occur in the pustules. The true hemorrhagic variola has been described under many names. It is the black small-pox, or variola nigra of Sydenham,—the purpura febrilis et variolosa, the black death (Hebra), etc.

35 among the 326 cases were examples of this grave form of disease, in which the pustules were absent, and replaced by cutaneous hemorrhages. The patients were generally robust, well nourished persons, in good hygienic conditions,—only 7 acknowledged alcoholic habits. The disease began suddenly with a severe chill, followed for two or three days by headache, pain in the loins and limbs, vertigo, insomnia, vomiting, and a diffused scarlet coloration of the skin more suggestive of scarlatina than of small-pox. The fever was moderate, an important circumstance for the prognosis. In only 6 cases did the temperature reach 40° (Cent.)

On the 3d or 4th day appeared the phenomena connected with diffused hemorrhages. The skin became swollen, principally at the face, and the erythematous blush spread further, and assumed a darker hue, often violet, in many cases black. Maculæ and petechiæ appeared,—not raised above the level of the skin,—with here and there vesicles filled, not with pus, but blood. The mucous membranes changed color with the skin,—hemorrhage as a rule making its first appearance in the subconjunctival connective tissue, that swelled and formed a prominent ring around the cornea. At this stage the appearance of the patients was frightful; the face darkened and swollen, the

eyeballs staring, with lurid red conjunctivæ, the entire expression in the highest degree anxious.

On the 4th or 5th day, rarely earlier or later, occurred profuse hemorrhages from the nose, urinary passages, vagina, rectum, lungs, sometimes also from the stomach, which lasted till death, and could be arrested by no kind of treatment. The temperature then fell, even below the norme; the heart and pulse were more rarely affected.

The organs of circulation, however, presented characteristic conditions throughout the disease. The cardiac impulse was powerful and heaving,—the sounds loud,—the pulse less frequent, full and hard. The arterial wall was very resistent: the veins, frequently observed in operations for venesection or transfusion, were incompletely filled, but their walls so stiffened that after section they often remained gaping and extremely friable. Nearly all the patients complained of præcordial anxiety and intense pain about the heart.

The respiration frequently presented curious irregularities of rhythm; being interrupted from time to time by a complete pause, this followed by a succession of shallow respirations, that gradually deepened to dyspnœa;—then came the pause again.

Nervous symptoms were prominent. Hyperæsthesia of the skin, or anæsthesia, paralysis of one or more of the limbs, deafness or amaurosis, were observed in various cases. The consciousness was usually intact, but sometimes coma set in a few hours before death.

Multiple hemorrhages were the principal lesions discovered at the autopsy. These were found constantly in the cutis and subcutaneous connective tissue, the respiratory and intestinal mucous membranes, the parenchyma of the lungs, the voluntary and cardiac muscular fibres, the sexual organs, and in the sheath of the great nerves. This last locality explained many anomalous nervous symptoms, especially the alteration of the respiratory rhythm, by hemorrhage around the vagus. The cardiac neuralgia was similarly explained, since, according to the researches of Goltz, the heart receives its sensitive nerves from the vagus.

These symptoms and lesions appear at first sight to remove the hemorrhagic variola very far from the confluent pustular small-pox.

But cases of the first only occur during epidemics of the second variety, and may communicate that second form by contagion. There are, besides, many cases that establish intermediate degrees between the two.

The author recalls the microscopic researches of Auspitz and Basch, Ebstein and Wagner, on the formation of the variolic pustule, which was shown to be an inflammation of the derma, and then inquires into the cause of this inflammation. This is evidently some specific chemical irritation, which the author thinks is unquestionably due to the presence of Bacteria. Certain form-elements have long been noticed in the pustule, that appeared to possess a definite relation to the morbid process. The first observations were made by Gluge in 1838. They have been extended by Hallier, Keber, Klebs, and Wagner. Of great importance for the author's thesis in regard to the essential identity between confluent and hemorrhagic variola is the fact, that these same elements have been discovered in the corium in cases of the last disease, by Erismann, Weigert and himself. Finally, Cohn (Virchow's Arch, 1872) has demonstrated that these "form-elements" are really Bacteria, which, in the fresh lymph, appear as extremely small, granular, colorless corpuscles, possessed of molecular but not independent movements.

The resemblances and differences between pustular and hemorrhagic variola are explained by the different situations of the bacteria in the two cases, as actually demonstrated by the microscope. In the first form they are found in the lymph of the pustules; in the second are accumulated in the terminal arteries in masses of sufficient size to constitute emboli. At the same time the walls of the arteries are found to be in fatty degeneration. The two conditions together explain the hemorrhages. Moreover, this extensive formation of emboli implies that an enormous excess of Bacteria exist in the blood in the hemorrhagic small-pox, and this excess corresponds to the singular fatality of this form of the disease.

The author lays no stress upon the decomposition of the blood which must also exist in these cases, and which is evidenced by the rapid march of fatty degeneration in the arteries. He utilizes the facts above related, in some interesting explanations in regard to certain details of the hemorrhages; *e. g.*, their absence in the liver and spleen, and their first appearance on the face and especially the forehead. Leaving these points from want of space, we will dwell in conclusion upon the author's remarks on the therapeutics of this frightful Disease.

After pointing out the unsatisfactory results obtained from ordinary treatment, he selects three substances as alone responding to the antiseptic indications that must be the basis of all rational treatment in all forms of small-pox. These substances are benzol, toluol, and xylol.* The benzol is extremely diffusible, and rapidly eliminated from the lungs. The toluol and xylol become oxidized in the blood, the first to hippuric, the second to toluric acid—the last more difficultly decomposed. It is on this account preferred by the author. Doses of 10-15-20 drops are given in a mucilaginous potion with essence of peppermint and sherry-wine.

The most essential result of this treatment, freely employed in pustular variola, is a coagulation of the contents of the pustule. If a pustule be opened after several days' treatment, the base seems to be covered with a solid fibrinous deposit, which often forms concentric layers (the débris of dead Bacteria?).

Hence the pustules rarely burst, and the period of drying is hastened and freed from complications, especially those of purulent absorption. Very little influence was exerted on the temperature.

The author only speaks of the application of xylol to pustular small-pox. We can only infer the theoretical utility of its administration in the initial stage of the variola hemorrhagica, as an attempt to diminish the number of Bacteria in the blood, that otherwise so soon become overwhelming.

It is to be regretted that this very interesting memoir does not contain more details and statistics in regard to the results of a treatment yet under litigation.

The author states in the beginning that of the 53 patients of the third grade (confluent pustules), he lost 9, or 16.1 per cent.

RESPONSIBILITY AND DISEASE. BALFOUR BROWNE, Author of Medical Jnrisprudence of Insanity; Law of Carriers, etc. London: Baillière, Tindall & Co. 1873.

THIS essay is written for the purpose of demonstrating that the scientific difficulty of establishing the precise limits between sanity and insanity is no practical excuse for not enforcing a local distinction between them. It is principally intended as a reply to a paper by Dr. Rns-

* See also Burkhart. Ueber die Anwendung des Xylol bei Pocken. Berlin. Wochensch. 1872.

sell Reynolds, who recently, before the British Medical Association, has declared:

1st. That delusion constitutes no criterion of insanity. 2d. That consciousness of right and wrong is equally unreliable. 3d. That the doctrine of partial insanity is untenable. In regard to the first statement the author declares that the law does not regard delusion as a test of insanity, and "does not define insanity, *except* in so far as it exempts the individual afflicted with it from punishment." But it is not made clear, by Mr. Browne at least, how the law performs its duty of "practical interpretation," in regard to this important exception, which is the whole case at issue.

The author replies to the other two objections together, asserting that the existence of moral consciousness in regard to some subjects and not to others, where there is intellectual delusion, is itself a clear proof of the possibility of partial insanity. Whatever be the scientific definition of monomania, it is extremely important, practically, that those affected merely with a slight mental aberration be left in enjoyment of the majority of their rights for which they are fit.

Mr. Browne concludes that the present law in relation to insanity is not nearly so bad as enthusiastic psychologists would have us suppose, and that accurate scientific tests are unnecessary for practical decisions based on averages and probabilities.

ARCHIVES OF SCIENTIFIC AND PRACTICAL MEDICINE. Edited by C. E. BROWN-SÉQUARD, assisted by E. C. SEGUIN. No. 2. February, 1873.

WE were accidentally prevented from noticing the first number of Dr. Brown-Séquard's journal, and of congratulating the profession on the valuable accession to our periodical literature, coming to us under such distinguished auspices. We should be sorry that the second number should meet with such apparent discourtesy at our hands. No. II. is not inferior in interest to No. I., for although the papers are not numerous, they contain a good deal of original matter, and are eminently suggestive, even when not comprehensive. We think, however, that Dr. Neftel, in his article on the Diagnosis of Cancerous Diathesis, seems to lay rather undue claim to originality for the statements "that malignant tumors, for instance carcinoma, are of local origin," and that "the prognosis depends upon the circumstance whether the affection is still local, or has already become generalized." We believed this principle to be universally admitted; it is enforced with emphasis in Broca's recent treatise on tumors. Dr. Neftel, however, renders service in pointing out the presence of indican in the urine as a sign of hepatic cancer, and quotes three cases where this sign served as a basis for a correct diagnosis, though no tumor could be detected. He does not prove, however, that the cancer is the exclusive condition that causes indican to appear in the urine, or that other profound disorders of nutrition would not have the same effect. The assistant editor, Dr. E. C. Seguin, contributes some interesting cases of a peculiar form of disease, called by him Tetanoid-Pseudo-Paraplegia. The paralysis is dependent on tonic spasm of muscles of the lower limbs, and is caused by compression of the anterior part of the spinal cord. It is an affection analogous to spinal epilepsy and writers' cramp.

Another interesting paper is by Dr. Bulkley on the use of tar in various skin diseases. There is a short article by Dr. Dupuy on a new method for arresting headache by means of injection of carbonic acid gas into the pharynx, and description of an apparatus devised by him for this purpose, accompanied by a drawing by which the instrument could be imitated. We have, besides, a very interesting review by Dr. Francis Delafield, on existing theories in regard to the origin of cancer, principally those of Thiersch and Waldeyer, who trace carcinoma exclusively to epithelial cells, and a little paper by Dr. E. Seguin on family thermometry in scarlatina. But the most important features of the number are the three articles by the Editor himself. The first is on the mechanism of symptoms in diseases of the brain, in which these symptoms are traced to irradiated irritations, essentially similar to those that occur in peripheric disease. The second exposes facts showing that hemiplegia may exist on the same, as well as the opposite side of lesions in the brain or medulla. The third article is on the production of ecchymoses as a consequence of cerebral lesions. The translations, reviews, and analyses fully justify the promise of the prospectus. It is with the greatest pleasure that we witness the establishment of this American archives, for which a wider place than usual has just been created by the cessation of Dr. Hammond's *Psychological Journal*. We trust that it will become a worthy rival of the scientific archives now in course of publication in Paris, and of which Dr. Brown-Séquard still retains supervision.

MENDENHALL.—Dr. Geo. Mendenhall, of Cincinnati, Ohio, now at Wiesbaden, has been elected a Fellow of the Royal Obstetrical Society of London.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, Dec. 11, 1872.

DR. A. L. LOOMIS, PRESIDENT, in the Chair.

DR. DELAFIELD presented a specimen for a candidate.

DR. FINNELL exhibited a specimen of gunshot wound. The immediate cause of death was a pistol-shot wound of the right auricle and left ventricle of the heart.

PRIMARY CANCER OF THE MEDIASTINUM, ETC.

DR. JOHN A. LIDELL presented a specimen of primary cancer of the mediastinum, with the following history:—

MR. PRESIDENT:—I have here a very interesting specimen of internal carcinoma. It is interesting, in the first place, because the primary seat of the disease was in a very unusual part of the body, namely, the mediastinum and root of the neck; and, in the second place, because the carcinoma, by encroaching upon certain of the organs contained in the mediastinum, disturbed their functions, and thus induced a remarkable train of morbid phenomena.

The subject was a gentleman, aged 57, who formerly had been much overwrought by the cares of business, and suffered from neuralgia of the head and neck. I was called to him on the afternoon of Friday, November 22d, and found him complaining of dyspnœa and extreme prostration. He said he felt too weak to get upstairs to his own room, or even to walk across the room wherein he sat, but, he had just returned from Brooklyn, a distance of several miles, whither he had gone to consult a homœopath, as he had been in the habit of doing daily for some time.

He said he should not go there any more, as he was too feeble. Face tumid and of a leaden hue; hands also tumid and cyanosed; breathing 30 to 36, short and loud, or noisy; much short dry cough; sharp, dry, hissing sounds were heard all over the back part of chest, excepting one patch of hepatization in right lung; at times his breathing was so loud that it could be heard in the next room while the doors were closed; heart laboring heavily; pulse 120 to 124 and irregular; mouth-temperature 97¼°; feet and ankles markedly œdematous, *i. e.*, they were puffed up with a tumefaction which pitted under pressure and presented the tense, shining, white, semi-transparent appearance of anasarca; the neck, especially at its root and on the right side, was the seat of a rather peculiar swelling; it was located beneath the deep fascia, hard and unyielding in feel, also nodular, as if the cervical lymphatic glands were implicated, but none of the nodules were movable; in short, the parts involved in the cervical swelling felt exactly as if they were matted together with some dense material.

On inquiry I was informed that the dyspnœa began only three days before; that it had increased very rapidly, and was worse by spells, or occurred in paroxysms; learned also that the œdema of the feet was first noticed on the previous day, and that the face and hands had presented a more or less tumid and blue appearance for some considerable time, much more, however, on some days than on others, and increasing or diminishing without apparent cause; learned, furthermore, that the swelling in the neck first attracted attention about eight weeks before, and that for about three weeks it had prevented his sleeping in the recumbent posture by occasioning a feeling of constriction in the throat and impending suffocation whenever he attempted to sleep in that posture; he felt least uncomfortable when sitting upright and leaning slightly forward; sometimes he had to lean backward, and this change of posture was almost sure to bring on nausea, with increased difficulty of breathing; he swallowed with much difficulty; liquids only could be taken and then in small quantity at a time; he got sleep only in snatches, but without lying down, so much was he bothered by the sense of obstruction in his throat on falling asleep. Prescribed sinapisms 8 × 8 inches, and of full strength, to be applied to the breast and supra-renal regions, and kept on twenty minutes; also: ℞ Potass. bromid. ʒij; potass. iodide. ʒi; aqua menth. pip. ad f. ℥ ij. M. Sigma. A teaspoonful every four hours in water. And: ℞ Pulvis digitalis, grs. iv.; pulv. scillæ, grs. viii. M. Divide in pulv. No. 4. Sigma. A powder every eight hours.

Saturday, November 23d.—Breathing somewhat easier and chest-sounds less dry; pulse 124 to 130; cough much less troublesome, and loose; sputum puriform; every third or fourth one, however, was rust-colored or pneumonic; mouth-temperature 98¼°; but the œdema of his feet and legs was considerably increased. Applied dry cups in large number, more than 40, to the back part of his chest and loins.

Sunday, November 24th.—Prof. Clark saw him in consultation. Cough dry again and more troublesome; œdema of feet and legs much increased; pulse weaker, very frequent, and intermitting every second beat; pulse in right wrist at times not so distinct as pulse in left wrist; hands still lead-colored, but more swelled; subcutaneous veins on upper and inner part of right thorax, especially the ramifications of the internal mammary, much enlarged, and presented a varicose appearance, seemingly from internal obstruction; urine scanty, high-colored, and on standing deposits copiously a brick-dust sediment; urine reddens litmus-paper; testing with heat and nitric acid reveals an abundance of albumen; this specimen on standing over night in the test-tube deposited a great number of minute ruby-colored crystals of uric acid on the sides of the tube; the urine of the previous day had presented just the same abnormities and reactions; the urine of to-day, examined with the microscope, was found to contain much urate of soda, some epithelium from the bladder, many blood-corpuscles, with granular fibrinous casts and granular epithelial cells from the uriniferous tubes; the urine of yesterday was not examined microscopically. *Diagnosis.*—It was thought that the obstruction to the circulation of the blood in the upper part of the body, the symptoms of which were so strongly marked, was due to compression of the descending cava and innominate veins exerted by some new formation in the mediastinum,—however, not aneurismal in character,—and that the same swelling at times diminished the flow of blood through the innominate artery. It was also thought that the dyspnœa was largely due to pressure on the trachea and bronchi and their attendant nerves which this swelling exerted, although some pulmonary œdema was present; and that the dysphagia was due to the same cause operating on the œsophagus. Finally, it was thought that the renal disorder had, in great part at least, resulted from the venous hyperæmia that necessarily followed the pulmonary congestion or inability of the blood to pass through the pulmonary capillaries. *Treatment.*—Dry cups were applied to his breast today; and acetate of potassa as a diuretic, wine-whey as a stimulant, quinine and iron as a tonic, with a mustard pediluvium and a sinapism to the epigastrium, were also ordered.

Monday, November 25th.—Some slight improvement in his pulse and strength was noticed, but on the other hand the œdema of his lower extremities was greater, and the flow of urine was not increased. Spiritus Mindereri was added to the acetate of potassa as a diuretic.

Tuesday, November 26th.—Worse in every respect; no diuresis, and anasarca much increased; rapidly growing weaker and longs for death; pulse 124, feeble and irregular; respiration 40; dyspnœa very urgent, and dysphagia great; moist rattles of œdema heard in all the pulmonary air-passages; countenance, etc., of a dull leaden hue. He continued to grow worse, and died on the following morning (Wednesday) at 8 o'clock, suffocated with pulmonary œdema.

Autopsy. 55 hours after death.—Cadaver rather thin in flesh and apparently in a good state of preservation; it had been kept on ice; extremities œdematous, especially the feet and legs.

Head.—Skull rather thick; dura mater somewhat more strongly adherent to it than usual; brain large. Sinuses of dura mater and veins of pia mater distended with dark-colored blood. On slicing the brain, however, the puncta vasculosa did not appear to be enlarged. The hyperæmia was venous and entirely passive in character. The visceral arachnoid exhibited opacity with considerable thickening of an old date, and some puckering from cicatrix-like contraction about the crura cerebelli, especially on the right side; but in other respects the arachnoid was normal. Brain-substance rather soft from post-mortem change, but otherwise normal.

Thorax.—On raising the sternum the mediastinum was perceived to be enlarged or widened and indurated by an adventitious growth, especially in its upper part, and the enlargement projected considerably more upon the right than upon the left side of the median plane.

The left pleural cavity was empty. The left lung was free from adhesions, large in size, much darkened in color, œdematous, and congested with venous blood. Its parenchyma appeared to be somewhat softer than natural, probably in consequence of post-mortem change. The congestion was entirely passive.

The right pleural cavity contained about sixteen ounces of blood-stained serum. The right lung exhibited some old pleural adhesions about the upper lobe, especially between its anterior free margin and the mediastinum. It was also blackened, œdematous, and congested, and its inferior lobe was in part the seat of hypostatic pneumonia.

The bronchiæ of both lungs were filled with frothy blood-stained serum, and the bronchial mucous membrane was deeply reddened. The bronchial glands were not particularly enlarged. Some of them, however, were quite dark (almost black) in color, but perhaps they were no darker than they should be in a subject of 57 years.

The pericardium contained about three ounces of bloody serum. The heart was rather fatty on its exterior, and quite flabby. It also appeared to be somewhat enlarged. On opening it, however, the right chambers, especially the right auricle, were found to be distended with recent coagula, which caused the organ as a whole to present an hypertrophied appearance, while in reality it was no larger than it should be. The cardiac valves were all free from disease.

Abdomen.—The liver was somewhat shrunken and nutmegy in appearance. Its parenchyma was softer than natural, and the seat of venous congestion. It also contained half a dozen firm, yellowish-white, spherical or egg-shaped deposits of carcinoma. They ranged in size from that of a grape to a lime. Some of them were softer at the centre than at the periphery. Some of them also were visible through the peritoneal coat of the organ and projected somewhat above the surrounding surface. The gall-bladder contained about an ounce and a half of dark-colored bile.

The spleen was rather small in size, but natural in color and structure.

The kidneys (both) were rather large, flabby, and considerably darker in color than natural. Their capsules adhered somewhat more firmly than usual. On section, the cortical substance presented a deep claret or maroon color. The renal parenchyma obviously contained much more than the normal quantity of blood. It was also softer than natural.

The stomach contained a considerable quantity of dark-colored liquid. The intestines were rather empty and contracted.

The tissues generally seemed more inclined to take on putrefactive changes than usual, just as they not unfrequently do in cases where death has resulted from acute albuminuria.

On examining more closely the diseased mediastinum it was found that the normal connective tissue had disappeared to great extent, and that its place had been usurped by a new growth of a yellowish-white color and firm or dense and brawny consistence, which had matted and blended or fused together all the organs contained in the upper part of the mediastinum. It was not limited or encapsulated anywhere. Moreover, it presented to the unaided eye the appearances which usually belong to rapidly growing scirrhus and fibro-plastic carcinoma. The ascending aorta, arch of the aorta, arteria innominata and its terminal branches, together with the left carotid and left subclavian arteries, the descending cava and the great veins belonging to the root of the neck, the trachea, the œsophagus, and the great nerves accompanying them, were all more or less completely embedded in and surrounded by this new formation. As already stated, this new structure was much more abundant on the right than on the left side of the median plane. It also extended upwards into the neck, beneath the deep fascia and among its reduplications, mainly on the right side, some considerable distance, but exactly how far we cannot tell, for we were not allowed to complete the examination in that direction on account of the disfigurement of the corpse which would result therefrom, but it seemed to gradually diminish in quantity and thus fade away.

Microscopical Examination.—A specimen taken from the mediastinum (it was scratched from the surface of a freshly made section with the point of a scalpel), and examined under the microscope, was found to contain a multitude of cells of various sizes and shapes, but most of them were small and round, elliptical or oval: some, however, were much elongated and almost club-shaped; occasional caudate and spindle-shaped cells were seen; some very large cells were also observed, which contained several small ones in their interior; besides, two or three bands of fine fibres were noticed.

Some of the milk-like juice obtained from one of the hepatic nodules and examined under the microscope, was found to be made up of cells which exhibited much variety in size and shape. Most of them, however, were either spherical, ovoid, or elliptical. But some of them were so much elongated as to be very nearly club-shaped. Occasionally one was caudate, and a few were fusiform. To the unaided eye the hepatic nodules appeared to belong to the medullary variety of carcinoma.

The lesion which immediately caused death was that of the kidneys. It induced general dropsy (anasarca), with dropsical effusion into the pleural and pericardial cavities, and into the pulmonary tissue and air-tubes, and thus the patient died asphyxiated.

Dr. Lidell, in conclusion, inquired if it was not rare to find cancer invading this particular locality as a primary affection.

Dr. Delafield replied that there were several such on record.

Malignant Disease of Bone.

Dr. F. H. Hamilton presented a specimen obtained by amputation at the shoulder-joint. The patient was a male, aged 40, whom Dr. H. first saw within the past year. A month or two preceding the said visit the patient had suffered considerable pain in the region of the insertion of the deltoid, and a day or two before the visit, in attempting to lower a window-sash, he had hurt his arm. It turned out on examination that the last injury had resulted in a fracture three inches below the lower end of the humerus. The existence of a fracture was not recognized by a very intelligent practitioner who first saw the case, because there had been no displacement. Splints were applied, and in the course of time the bones united. From the time the bone was broken until it united there was no pain, but as soon as the union was complete the suffering was as great as it was before. The pain continued and the bones enlarged, when a few weeks ago the arm was broken again. The exploring needle was introduced into the swelling, and penetrated the substance of the bone without resistance. The case was considered a very serious one, and Dr. Markoe, who was called in consultation, agreed with Dr. Hamilton in the expediency of an amputation. The amputation was accordingly performed, assisted by Drs. Markoe and Arnold.

The specimen presented consisted of the humerus, surrounding which was a matted mass of muscular tissue and fascia in a state of fatty degeneration. The seats of the previous fractures were well shown; the first low down, the second higher up.

Both fractures were somewhat transverse, a circumstance which led to the diagnosis of bone disease as the cause of the same.

The character of the lesion in the bone had not been determined, but it was plainly enough degenerative, and was in all probability malignant. The laminated tissue was expanded and softened, and in some parts was substituted by others.

Dr. Sands thought that the disease in question was a rare form of osteo-myelitis rather than cancer. It looked to him as a typical example of osteo-myelitis, in which the compact tissue of the bone had undergone a rarefaction and in some places become absorbed, and in which the marrow and endosteum had in both instances become ossified. He could see no trace of what he should consider a malignant growth, but on the contrary a good deal of adventitious and bony tissue, partly derived from the periosteum, but mainly derived from the endosteum, which had become ossified to the extent of obliterating the cylindrical canal. In the upper part of the specimen the tissue was attenuated and the marrow absorbed. In one portion there was a soft pulpy deposit, looking like pus. The occurrence of a fracture from slight causes would go as far towards substantiating the opinion that the case was one of osteo-myelitis as of cancerous degeneration.

Dr. Hamilton doubted the soundness of the opinion of Dr. Sands. He admitted that there were many appearances present in the specimens which were met with in examples of osteo-myelitis. He remarked that the disease had existed a whole year, and during that period of time there was ordinarily more or less necrosis. In the present instance no necrosis was found. He was familiar with examples of osteo-myelitis which terminated in that degree of degeneration observed in the specimen. He was aware that the bone softened, but such softening was extraordinary and unequivocal. This softening very soon hardened, and this hardness soon became very firm. He was, however, content to keep his opinion in abeyance until the microscopical examination had been made.

Dr. Sands stated that this form of osteo-myelitis was rare. The German pathologists describe two distinct varieties,—one in which the process of sclerosis goes on, and the other in which a rarefaction of the tissue occurs. He believed he had seen examples of both of these.

Dr. Markoe did not recognize the specimen as belonging to any of the cases of osteo-myelitis with which he was accustomed to meet. He had never seen any go to that stage without pus being formed or necrosis resulting; none which brought into its substance by a process of degeneration all the surrounding soft tissues.

Dr. Lidell was inclined to believe the disease malignant, never having seen a case of osteo-myelitis at all resembling it.

Dr. Delafield took the side of benignancy. If it were a malignant disease of the bone, the most frequent primary cause of such would be a sarcoma, but sarcomata did not present any of the appearances seen in the specimen. If it were a case of cancer it would come nearer to such as occur secondary to cancer in other parts. To such it did not even bear a resemblance. The appearances of the specimen were stronger in favor of osteo-myelitis than malignant disease, even without reference to the clinical history.

ACUTE ATROPHY OF LIVER.

Dr. Robert Watts presented a specimen of acute atrophy of the liver, with the following history:—

Wm. S. R———, age 22, a native of South Carolina. Had enjoyed good health previously, with the exception of an attack of remittent fever a year ago.

On *Monday, Nov. 25th*, after having passed a restless night, he complained of nausea and pain in the bowels, which he attributed to having eaten freely of pickled fish the previous evening. At noon he took ʒ ijss. of mustard in a tumbler of water, and also a copious enema of soap-suds, both of which were retained. The pain in the bowels was relieved, but the nausea continued. There was some acceleration of the pulse, and the temperature was above normal. At 4 P.M. he took another enema containing ol. ricini ʒ i., which was also retained. In the evening he felt pretty well, and slept during the early part of the night, after which he became restless.

Tuesday, Nov. 26th.—Complained of headache and pain in the back, and at 9 A.M. had a chill which lasted half an hour, and was followed by high fever (pulse 144 and temperature 104½°), which was succeeded by moderate sweating. By evening he was free from pain, and the pulse and temperature were normal. During the day food had been distasteful to him, but he drank freely of lemonade.

Wednesday, Nov. 27th.—Had a very restless night, and again complained of great pain in back and hypogastrium, and of headache. At 8.45 a severe chill occurred suddenly. This was checked by ʒ ss. of chloroform, which, however, was vomited after half an hour. Fever followed, with a pulse of 156 and temperature of 106°, and this was succeeded by a little sweating. All day he refused nourishment and drank sparingly of lemonade. The tongue was a little dry. The urine was scanty and high-colored, but it contained no albumen. During the afternoon he vomited two or three times. In the evening the pulse was 80, temperature normal.* At 4 P.M. he took quinia sulphat. grs. v., and at 8 P.M. mass hydrarg. grs. x. During the night was very restless, and complained of great pain in the stomach. About midnight he vomited a transparent light green fluid, and after this had frequent retching.

Thursday, Nov. 28th.—At 6½ A.M. took ol. ricini ʒ vi., and at 7½ A.M. quin. sulp. grs. x. Complained of severe pain in the lumbar region, but had no chill. During the whole day the vomiting and retching continued. He drank occasionally of cold milk, which was almost always vomited after a little time, and frequently showed no signs of coagulation.

To-day the sclerotic shows a yellow tinge. In the evening the features were pinched, tongue dry, pulse 130, temperature normal. Pain in back severe, principally in right side. During to-day took quin. sulp. grs. iij. every four hours, and half an ounce of brandy in milk three times.

Friday, Nov. 29th.—Vomiting and retching continued during night. Pulse 70, weak, and a little irregular. Temperature normal. Icterus well marked. Pain over liver very severe, with exquisite tenderness. Applied two leeches with some relief to pain, and afterwards kept dry hops applied hot. Bowels were moved three times, the first since Tuesday.

During to-day has been wandering in mind, but was easily roused, and would then talk rationally.

This afternoon a "coffee-ground" appearance was noticed in the vomited matter, which under the microscope was found to contain blood-corpuscles, large quantities of pigment, oil globules, and epithelium.

* On percussion the liver was found somewhat enlarged, and its edge could be felt an inch below the free border of the ribs.

The urine to-day was smoky and thick, and contained a large amount of albumen and some blood, but no casts.

Has taken quin. sulph. grs. iij. every three hours, with beef-tea and brandy per rectum. In the evening pain over liver had nearly ceased. Pulse 85, temperature normal.

Saturday, Nov. 30th.—Had a better night and got some sleep. Pulse 120, temperature 99°. During the day stomach was quiet, and he took considerable nourishment (beef-tea, milk, and brandy). Was mildly delirious but easily aroused. Has been comparatively free from pain. Omitted quinine.

At 7 P.M. Dr. Loomis in consultation. Pulse 144, temperature 99¾°, respiration 27. Urine drawn this evening was heavily loaded with albumen and contained blood, as did also the vomited matter. Percussion over liver showed dulness between the sixth and eighth ribs, none below. Abdomen retracted, and palpation caused little pain. A systolic murmur heard over base of heart and transmitted along vessels. No dulness over the chest, but the respiratory murmur could not be heard on the left side posteriorly. Pupils contracted. Tongue moderately dry. Dr. Loomis suggested the presence of acute yellow atrophy of the liver. Is wandering in mind, but easily aroused. Has had hiccough frequently yesterday and to-day. From this time patient grew steadily worse. At midnight pulse 140, temperature 100½°, respiration 34. Is not easily roused.

4 A.M. Comatose. Pulse 136, temperature 100¼°, respiration 48. Dulness over both sides of chest, more marked on the right; only bronchial respiration over the upper half of each lung. At 5.35 respiration gasping, face cyanotic, pulse intermittent and felt only in femorals.

5.58. Pulse stopped, the respiration having ceased first.

Dr. Francis Delafield has kindly furnished the following report of the autopsy made by him 7½ hours after death:—

Body deeply jaundiced.

Head not examined.

Heart.—Small ecchymosis in the visceral pericardium; small patches of atheroma in the mitral valve; heart walls firm.

Lungs.—Both lower lobes congested. In the left lower lobe a single infarction the size of an English walnut, with a firm yellow centre and red edges.

Liver is 9 inches long, 6 inches wide, 3½ inches thick, and weighs 2 lbs. 10 oz. It is of firm consistence, of light yellow color, mottled by red spots in the centre of each of the acini.

The gall-bladder contains a small quantity of thick black bile.

By firm and steady pressure this can be made to flow through the common duct into the duodenum. The liver-cells are nearly all swollen and filled with small shining particles, so that some of them look almost black by transmitted light. In a very few places the cells are broken down into a mass of granules and fat.

The *stomach* contains a little blackish fluid. Its mucous membrane is of a grayish-white color.

The *duodenum* is empty; its mucous membrane is of a grayish-white color.

The *spleen* is of medium size, not softened, and of a pinkish color.

The *kidneys* are large; both pyramidal and cortical portions are swollen. The markings of the cortex are regular, but obscured by an increased congestion. In the papillæ are a number of yellow lines parallel to the tubes. The epithelium throughout is swollen and finely granular. In some of the convoluted tubes there is a little blood. In many of the straight tubes, especially in the papillæ, blood and granular matter have accumulated so as to fill them completely.

Dr. Delafield remarked that the liver was much firmer than was usually seen in such cases, owing, perhaps, to the early period of the autopsy. The minute lesions, although well characterized, were not so far advanced as regards breaking down of the cells, although the case was of the usual duration.

MYELOID SARCOMA OF CHOROID.

Dr. C. M. Allin presented a specimen of myeloid sarcoma of the choroid. The patient, aged 38, from whom it was removed, noticed by the merest accident that the vision of one eye was gone. This was about four years ago, when wiping one eye she discovered that she was in darkness. She applied to a physician, who assured her that her trouble was only temporary. Not improving, however, as she expected, she consulted other medical gentlemen, and lastly presented herself to the State Medical Society of Vermont. At that time an opacity of the cornea had appeared, and the physicians who then saw her pronounced her case one of cataract, but would not advise an operation. She came to the city a fortnight ago, when Dr. Allin removed the tumor.

On examination, she presented a tumor of the orbit projecting an inch and a half beyond the orbital margin. The conjunctiva was stretched over the growth, but at no point had it given way. The cornea had sloughed within the week previous. There was no particular pain complained of until the sloughing occurred. She had no enlargement or protrusion of the eye until last September, since which time the growth had increased very rapidly.

The operation was performed by dividing the conjunctiva close to the palpebral margin, then removing the tumor and all the tissues of the orbit that could be reached, dividing the tumor far back at the base of the orbit. A paste of chloride of zinc was then freely applied to the base of the orbit and also to the edges of the lids to promote sloughing of the same. The nerve stump was found infiltrated with diseased matter, necessitating the application of the caustic.

The specimen showed the eye but very slightly encroached upon. The disease had evidently commenced in the choroid, pushing forward the retina, involving not much more than one-quarter of the globe, and rupturing the sclerotic in its posterior portion very near the nerve. Since the rupture of the globe the disease had extended itself posteriorly.

Dr. Delafield, to whom the eye had been given for a microscopical examination, also called attention to the fact that the greater portion of the growth was extra-ocular; that it commenced behind the choroid, was thickest at the fundus, becoming thinner as it passed forwards. Continuous with this, through the sclera, was the extra-ocular growth surrounding the nerve, splitting into layers and in part replacing the nerve elements. This growth was prolonged within the sheath as far back as the section of the nerve. The manner in which the growth had extended itself from a small growth within the eye to a larger one outside was not usual. If the eye had been extirpated earlier, before the sclerotic coat had been perforated, and the disease extended itself outside, the prognosis would have been favorable. He had under his own observation two cases of these strictly intra-ocular growths in which the respective immunity from a return was three and five years.

Dr. Allin referred to a case in support of the unfavorableness of prognosis when the tumors became extra-ocular. The patient was a man who was examined early and found to have a simple detachment of the retina caused by a growth underneath. Extirpation was recommended, but the patient declined to have the operation performed. Finally, the tumor filled the whole of the interior of the eye, a small portion appearing as a little nodule externally. The pain was so excruciating that the patient then gladly embraced the opportunity of removal of the disease. The operation was duly performed, and the wound healed perfectly. He continued well for three years and a half, at the end of which time a small nodule appeared on the anterior wall of the abdomen. This was followed by three or four similar ones in the groin; soon after cerebral disturbance appeared, and he died within two months from the reappearance of the disease.

Dr. Sands exhibited the patient from whom he had removed, a month before, the tumor of the antrum. The external wound had healed perfectly, and, with the exception of the lineal scar of the incision along the side of the nose, the wing of the nose, and through the median line of the lip, there was no evidence of any operation having been performed. The result of the operation in preventing deformity and paralysis of the facial, so common with the old method, was such as to commend the method to the attention of surgeons. The plan is that jointly advised by Fergusson and Langenbach.

Dr. Knapp, who had examined the tumor microscopically, pronounced it a myxo-chondroma, and illustrated the appearances presented by the different cells, and their relations to each other, by diagrams, microscopic preparations, and blackboard representations.

The Society then went into executive session.

New Instruments.

A CURRENT REVERSER WITH FLEXIBLE ELECTRODES.

By GEORGE M. BEARD, M.D.

The accompanying cut represents a current reverser that I have recently devised and perfected, and which is now constructed by Messrs. Tiemann & Co.

It differs mainly in this feature from other devices to accomplish the same purposes, viz.: *that the current is reversed by simple and slight pressure of the thumb,* without the intervention of a slide, or any complex arrangement whatsoever.

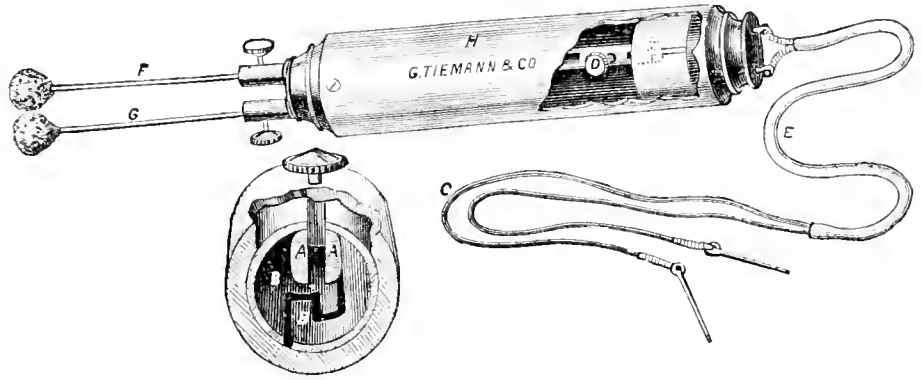
The letter D represents the button of the spring, by pressing which, the current is interrupted or reversed. Pressing it lightly, *interrupts* the current; pressing it firmly, *reverses* it.

In the vertical section of the hard rubber handle, A A is represented as springing up against the metallic plate on the upper and inner surface of the handle. Pressing this slightly down, metallic connection is broken and the current is interrupted; pressing it firmly down, the connection is made and *reversed* at B B, the metallic plate on the lower surface of the handle.

C represents the wires that connect with the battery, enclosed in a rubber tubing E.

F and G are flexible wire electrodes armed with sponges; they can be separated several inches and kept there, or put close together as represented in the cut. The advantages of this are these:—1. In many of the applications of localized electrization this neat and simple arrangement saves considerable expenditure of muscle on the part of the operator. One hand can be perfectly free while the other holds and guides the electrode. In electrifying the muscles of the hand and arm, and of the face especially, it is far more convenient than to use separate electrodes.

2. In cases of paralysis of motion and of sensation, where *voltaic alternatives* are sometimes indicated, this is the easiest conceivable method of reversing the current. I find the arrangement of the flexible electrodes very convenient in external applications to tumors, rheumatic joints, and sprains.



ARMY AND NAVY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from February 19, 1873, to March 3, 1873.

Vollum, E. P., Surgeon.—The leave of absence, granted by S. O. 25, Department of the Platte, February 15, 1873, extended 30 days. S. O. 22, Military Division of the Missouri, February 24, 1873.

Pope, B. F., Assistant Surgeon.—To accompany 7th Regiment of Cavalry to Fort Randall, Dakota Territory, and after completion of this duty return to Louisville, Ky., reporting to Medical Director of the Department. S. O. 40, Department of the South, February 26, 1873.

Hitchcock.—Prof. Edward Hitchcock, M.D., of Amherst College, Mass., has returned from his tour round the world.

Medical Items and News.

Long Island College Hospital, Brooklyn, New York.—The Introductory Lecture was delivered March 5th, at 8 o'clock P. M., by Professor John Byrne, M.D.

Medical College Commencements.—The Sixty-sixth Annual Commencement of the College of Physicians and Surgeons, New York City, was held at Steinway Hall, February 27, 1873. The exercises were opened by prayer by Rev. Marcius G. Hutton, D.D. The degree of Doctor in Medicine was conferred on 104 graduates by Edward Delafield, M.D., president of the College. The following announcement of prizes was made by Professor Dalton:—Graduating theses.—First prize to Landon R. Longworth, A.B., M.D., of Cincinnati, Ohio, for a thesis on "Ligature of the External Carotid." Second prize to Daniel H. Smith, M. D., of New York City, for a thesis on "Hydrocyanic Acid." Andrew H. Smith, M.D., received the prize of the Alumni Association for a thesis on "The Effects of High Atmospheric Pressure, including the Caisson Disease." Edward J. Birmingham, M.D., of N. Y., received the "Otis Prize." The "Thomas Prize" was awarded to Jos. D. Amway, of New York. The valedictory address to the graduating class was given by Chas. Kelsey, M.D., of N. Y. Rev. H. C. Potter, D.D., delivered the address to the graduates. The music was by the well-known Seventh Regiment band.

The Twelfth Annual Commencement of the Bellevue Hospital Medical College, N. Y. City, came off at the Academy of Music, February 27, 1873. Rev. Alfred B. Beach, D.D., chaplain of the College, opened the exercises with prayer. George F. Talman, Esq., president of the Board of Trustees, conferred the medical degrees on 167 graduates. Hon. John R. Brady, of the Board of Trustees, made the address to the graduating class. The valedictory address was given by John R. Kinney, A.M., M.D., of Hawaii, Sandwich Islands, a member of the graduating class. The proceedings were enlivened by the presence of an excellent band under the direction of Mr. Carl Bergmann.

Deaths.—Prof. Hugh L. Hodge, M.D., of Philadelphia, died February 26, 1873, in the 77th year of his age. He was born in that city, in 1797, of Scottish-Irish parents, and was educated at Princeton College. He entered the University of Pennsylvania, as a medical student, under the guidance of the late Dr. Caspar Wistar, of Philadelphia, and graduated in 1818, and immediately made the study and practice of obstetrics a specialty.

To the chair of Prof. Dewees, at the University, Dr. Hodge succeeded in 1835, and, with great distinction, retained it until 1863, when his advancing years compelled him to resign its attendant duties; the trustees thereupon conferred upon him the emeritus degree. In its days of prominence, Dr. Hodge was a useful member of the Kappa Lambda Society; he was also one of the editors of the *North American Medical and Surgical Journal*. In 1860, Prof. Hodge wrote a work on the "Treatment of Diseases of Women and Children," and in 1864 one on the "Principles and Practice of Obstetries."

The father of Prof. Hodge was the founder of the Second Presbyterian Church, of Philadelphia, and in the congregation attached to that church Prof. Hodge remained a devoted and useful member until his death.

Dr. Uriah G. Bigelow, late president of the Albany County Medical Society, and consulting physician of the Albany Hospital, died in Albany, February 24, 1873, aged 53 years.

Alumni Associations.—The annual dinner of the Alumni Association of the College of Physicians and Surgeons was given at Delmonico's, Wednesday evening, February 26, 1873, Dr. C. R. Agnew, president, in the chair. About 150 of the graduates were present. The following gentlemen responded to the toasts: Prof. T. Gaillard Thomas, M.D., Prof. Calvin Ellis, M.D., of the Harvard Medical College; Rev. Howard Crosby, D.D., LL.D., Prof. Fordyce Barker, M.D., Parke Godwin, Esq., Rev. Wm. Adams, D.D., John P. Crosby, Esq., Leroy M. Yale, M.D., B. F. Dawson, M.D., S. O. Vanderpoel, M.D., E. M. Hunt, M.D., and Dr. Hayes.

The officers of this Association for this year are as follows:—*President*, Prof. C. R. Agnew, M.D.; *Vice-President*, Robert A. Barry, M.D.; *Secretary*, Frederick A. Burrall, M.D.; *Assistant Secretary*, George Bayles, M.D.; *Treasurer*, T. M. Cheeseman, M.D.; *Committee on Prize Essays*, Drs. Geo. A. Peters, Gouverneur M. Smith, and Ellsworth Eliot.

The annual prize of $250 for the best essay was awarded to Dr. Andrew H. Smith.

The Alumni Association of Bellevue Hospital Medical College held its annual business meeting at the Mott Memorial Library, Wednesday evening, February 26, 1873, Dr. Charles A. Seale, first Vice-President, in the chair. The reports of the Corresponding Secretary and College Historian were read and approved. The election of officers resulted as follows:—*President*, Prof. Wm. T. Lusk, M.D.; *First Vice-President*, Thos. R. Pooley, M.D.; *Second Vice-President*, Frank H. Bosworth, M.D.; *Corresponding Secretary*, Bradford S. Thompson, M.D.; *Recording Secretary*, Geo. W. Wells, M.D.; *Treasurer*, Henry Raphael, M.D.; *College Historian*, Frederick A. Castle, M.D.

The annual dinner of this Association will come off in October, 1873.

Alumni Association, Med. Dept. University of New York.—The annual meeting of this association was held at Association Hall, Tuesday evening, March 4th, 1873. The exercises were opened with prayer by Rev. Howard Crosby, D.D., LL.D., Chancellor of the University. Introductory remarks were made by the Chancellor, and John Taylor Johnston, Esq., Vice-President of the Council of the University. The annual address was delivered by S. S. Satchwell, M.D., of North Carolina, class of 1845. The speeches and music were interesting and entertaining.

The annual business meeting took place after the exercises were finished. The following gentlemen were chosen officers for 1873-4: *President*, Dr. James R. Leaming; *Vice-Presidents*, Drs. Henry S. Hewit, Alfred L. Carroll, Wm. Cunniff, S. Fleet Speir, Bolling A. Pope, Thomas C. Finnell; *Secretary*, Dr. Charles Inslee Pardee; *Treasurer*, Dr. D. B. St. John Roosa; *Orator*, Dr. Alfred L. Carroll; *Executive Committee*, Drs. Jas. H. Anderson, Jos. S. Monell, Lewis Fisher, S. Seabury Jones, C. D. Varley, Harvey S. Gay, Jos. W. Howe, Stephen J. Clark, F. R. S. Drake, Aug. W. Maclay, F. Le Roy Satterlee, John W. Hunt.

The following resolutions, with reference to the death of Dr. James L. Brown, were unanimously passed.

Whereas, It has pleased Almighty God to remove by death Dr. James L. Brown, an alumnus of this University; therefore,

Resolved, 1st, That the Alumni have sustained an irreparable loss.

2d. That we extend to the family and friends of the deceased our cordial and affectionate sympathy.

3d. That we commend the example of our deceased friend and associate as one worthy of our imitation and emulation as illustrating the character of a true gentleman and accomplished physician.

JAS. R. LEAMING, M.D., President.
CHAS. INSLEE PARDEE, M.D., Secretary.

NELSON.—Died at Gifford's, Staten Island, N. Y., March 1st, 1873, Dr. Robert Nelson, aged 81 years.

MEDICAL LIBRARY AND JOURNAL ASSOCIATION OF NEW YORK.—At the Friday Evening reunion of February 28th, 1873, Dr. J. C. Peters, President, in the chair, Dr. H. G. Piffard made remarks on "Urinary Analysis," with practical illustrations. Dr. Neftel spoke of the spectroscopic analysis of the urine. The President announced the donation to the Association of a handsome framed portrait of Dr. Gurdon Buck, an ex-president, also an elegant one of the late Prof. Jos. M. Smith; the latter tendered by his son, Dr. Gouverneur M. Smith.

The following works were donated to the library:—Medical and Surgical History of the War—2 vols. from Surg. General U. S. A.;

Pharmacopœia of Mass. Med. Society, 1808—The first work of the kind published in the United States.

Pharmacopœia of New York Hospital, 1816.

Pharmacopœia of United States, 1820, 1828, 1864—three copies.

Statistical Report of the Sickness and Mortality in U. S. A., embracing a period of twenty years—1819–1839.

The last six volumes were given by the President, who has, on previous occasions, generously donated some of his rarest works to the Association.

UNIVERSITY OF PENNSYLVANIA.—Prof. George F. Barker, of Yale College, has accepted the call to the chair of Physics in the University of Pennsylvania, and will assume it about April 15th.

THE LATE DR. JAMES L. BROWN, OF NEW YORK.—At a meeting of the Medical Staff of the Demilt Dispensary, held on the 7th of Feb., 1873, the following preamble and resolutions were adopted:—

Whereas, It has pleased Providence to bereave us of our highly esteemed colleague, James L. Brown, M.D., we, the remaining members of the Medical Staff of the Demilt Dispensary, deem it a sacred, though a painful duty to give publicity to such sentiments as our associations with him have inspired. Therefore

Resolved, That in the most unexpected death of Dr. Brown we feel a personal affliction; for by it we have lost not only an associate and colleague, but a highly skilled medical counsellor and a brave and faithful friend.

Resolved, That his removal has deprived the Profession of an ornament and shining light; society of a citizen of the stanchest morality, who never knowingly did wrong, and who always dared to speak and perform what he believed to be right.

Resolved, That the Demilt Dispensary, to whose usefulness as a public charity he contributed in most of its departments during many years of service, has in Dr. Brown lost an officer whom it will be hardly possible to replace, and the public who have there sought his advice will rarely find in his place one of greater learning and fidelity.

Resolved, That the family of our deceased colleague have our sincerest sympathy and condolence.

Resolved, That a copy of this expression of our feelings be sent to the family of deceased, to the Trustees of this Dispensary, to the Pastor of St. Luke's Church, and be furnished the Medical Journals of this city for publication.

STEPHEN ROGERS, M.D.,
W. T. WHITE, M.D.,
EDWD. J. DARKEN, M.D.,
Committee.

THE LATE DR. J. S. L. TONELIER, OF NEW YORK.—At a meeting of the Board of Trustees of the New York Dispensary, held February 17th, 1873, the decease of Doctor J. S. L. Tonelier, a district physician of the Dispensary, on the 25th January, 1873, at the advanced age of eighty-five years, having been communicated, it was

Resolved, That the long continued and faithful services of the deceased as physician to the Dispensary well deserve a tribute of respect and acknowledgment from this Board. First appointed in 1840 and serving till 1845 (when he resigned), Dr. Tonelier was re-appointed in 1856, and continued in the performance of his duties till December 5th, 1872, the commencement of his last illness. His uniform regularity of attendance and devotedness to the care of the sick poor, continued for so many years and to such an advanced age, furnish a rare instance of professional fidelity that may well excite our admiration, and be a worthy example for imitation.

Resolved, That in his decease the Dispensary has lost a faithful medical officer, whose excellence of character was warmly appreciated by all his associates.

An extract from the minutes.

ROBERT B. CAMPBELL, *Secy.*

HUDSON COUNTY MEDICAL SOCIETY, N. J.—At the recent annual meeting of this Society, the following officers were elected for the ensuing year: *President*, Dr. M. A. Miller; *Vice-President*, Dr. J. D. McGill; *Secretary*, Dr. Henry Mitchell; *Treasurer*, Dr. H. H. Abernethy; *Reporter*, Dr. S. R. Forman.

HUDSON COUNTY INSANE ASYLUM, N. J.—This new asylum is about finished. Dr. Eddy, late Deputy County Physician, is to be the Superintendent.

DR. A. D. ROCKWELL has been appointed Electro-Therapeutist to the New York State Woman's Hospital.

DEATH OF PROF. TORREY.—Prof. John Torrey, M.D. and LL.D., the renowned botanist and chemist of Columbia College, died March 10th, 1873, in the 77th year of his age.

He was born in this city in 1798, and received his medical diploma in 1818 from the College of Physicians and Surgeons. In 1824 he was appointed Prof. of Chemistry, Geology and Mineralogy in the Military Academy of West Point. He occupied the chair of Chemistry and Botany in the College of Physicians and Surgeons from 1827 to 1855, and at the time of his death he was considered in Europe to be the foremost of American botanists, and a leading author of botanical reports and text-books.

THE BEST METHOD FOR REMOVING THE UPPER MAXILLARY BONE.

By JULIAN J. CHISHOLM, M.D.,

PROFESSOR OF OPERATIVE SURGERY IN THE UNIVERSITY OF MARYLAND.

As a surgeon, but more especially as a teacher of operative surgery, I have constantly occasion to consult authorities on the various methods adopted by surgeons for the performance of operations. In reviewing the *modus operandi* for extirpating the upper jaw, I have noticed that in the many works or practical surgery, even the most recent, but one mode of procedure is described. All of these books mention the curved incision through the cheek, extending from the external angular process of the frontal bone to the angle of the mouth; to be modified, if found necessary, by the addition of a horizontal incision running immediately beneath and parallel with the lower lid, and extending from below the inner canthus of the eye to the vertical cheek incision. If required, this horizontal incision may be made midway between the mouth and the orbit, extending from the wing of the nose directly outward to the curved incision already referred to. Mr. Fergusson had suggested an incision passing through the median line of the upper lip, then curving around the wing of the nostril and extending upwards in the line where the nose and cheek meet each other to within one-half or three-quarters of an inch of the inner canthus of the eye. When only a portion of the upper jaw is to be removed, this latter incision around the nose appears to be sufficiently extensive for exposing the surface. When a larger surface is to be laid bare, Mr. Fergusson adds this nasal incision to the curved incision extending from the angle of the mouth upwards. This curved incision through the side of the face is open to the very serious objection of leaving an ugly scar, to which is added paralysis of all of the muscles in front of the wound through division of the branches of the facial nerve. When the horizontal incisions are used, the face is much more extensively scarred and thereby permanently disfigured.

Having for many years taught and practised Dieffenbach's operation for the removal of the upper jaw as the best method, both as to the ready exposure of the entire bone and leaving the least deformity as a permanent result, I have been much surprised to find so little mention of this excellent method. Chelius, in his System of Surgery, refers to Dieffenbach's method in one line only. In the more recent works of Holmes, Erichsen, Fergusson, Gross, Gant, and others, the operation appears to have been completely lost sight of.

Dieffenbach's operation consists in making the incision in the median line of the face. Commencing at the root of the nose, an incision slits the nose and the upper lip in the median line. A short incision joining the first at right angles, extends from the root of the nose to the inner angle of the eye. The lower lid being drawn downwards, the knife is carried along the entire length of the conjunctival cul-de-sac, separating this lid from its orbital connection, and utilizing the entire length of the lower lid in the horizontal flap. When the flap, as defined by the vertical and horizontal incision, is dissected up, it will lay bare the entire front, and, if necessary, side of the face, without having divided any large vessel, or any important nerve-branch. With such an exposure the superior maxillary bone can be isolated with great ease, as every surface of contact with neighboring bones can be clearly brought into view. With no additional incision I found no difficulty in removing from the living subject the superior maxilla, malar, and palate bone, which enabled me to extirpate a large fibroid with extensive adhesions to the roof of the pharynx. After the removal of the maxilla, when the flap is brought back to its normal situation and carefully adjusted by several points of suture, union speedily ensues. This operation leaves so little deformity, that in the majority of cases the line of incision will escape detection unless the scar be sought. In many faces the thin skin is so stretched over the bridge of the nose as a normal condition, that it reflects light as a whitish lines somewhat similar to the scar made in this operation. The inferior lid retains all of its movements. The sides of the face present their normal appearances unscarred, with nerves and vessels intact. The eye-muscles can be so nicely manipulated through this bold flap, that all the movements are retained. As the suspensory ligaments of the eye-ball remain adherent to the roof and sides of the orbit, there is no drooping of the eye-ball. Immediately after the sutures are placed I have seen the patient move the eyes in parallel axis, showing perfect control.

Experience both on the living and dead subject has proved to me the advantages which Dieffenbach's operation possesses over all others designed for the removal of the entire upper jaw. I would recommend to those who may have this operation to perform, to give the method by median vertical incision a trial, feeling assured that those who have once used this better method will not go back to the incision through the cheek into the angle of the mouth, as described in most treatises on surgery.

A CHEAP AND SIMPLE SUSPENSION FOR THE LEG,

GIVING MOTION IN ALL DIRECTIONS.

By GEO. A. VAN WAGENEN, A.M., M.D.,

HOUSE SURGEON BELLEVUE HOSPITAL (SERVICE PROF. STEPHEN SMITH.)

On September 10th, a very bad horse-car accident, producing a compound comminuted fracture of tibia and fibula, was admitted to one of our wards. A consultation concluded to save the limb if possible, and I put it up immediately in plaster-of-Paris. The fenestra at each side of the splint had to be large; and, carefully as it was made to fit the leg, slight motion of the bones was inevitable on any attempt to raise or *turn* the limb; and pain in consequence. To relieve this pain, and prevent injury to the parts from motion, I made the apparatus here described.

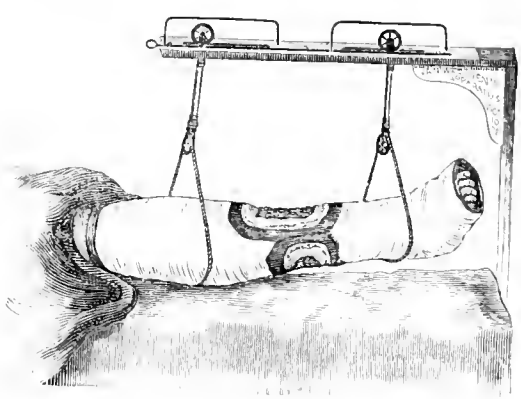
It answered these ends so perfectly, and is at the same time so cheap, that it was suggested others might be glad to avail themselves of it, extending its usefulness.

It consists of an elbow ┐ of wood projecting over the foot of the bed, from which the leg is suspended by two pieces of rubber tubing; one above the ankle, the other just below the knee. The tubes have common grooved iron pulleys or wheels at each end: Those above, rolling on a large iron wire to allow motion towards the head or foot of the bed; those below,

at right-angles to the others, holding the rings of rope in which the leg rotates;—this last being far the most important, allowing patient *to turn on either side*. Motion on these rollers is accomplished with so *little resistance* that there is *no pain*.

The upright of the elbow to go at the foot of the bed should be long enough to rest on the floor, or any convenient post of the bedstead, and project about two feet above the level of the mattress,—the horizontal piece long enough to reach nearly to the knee; pine $\frac{3}{4} \times 2$ inches is heavy enough. The angle made by these pieces is braced, and a strap of hoop iron outside makes it very strong. In the horizontal piece two slots are cut wide enough to allow the iron pulleys to pass through, and of sufficient length to allow the patient to draw himself up and down in bed. A $\frac{1}{4}$ inch iron wire passes the whole length of this piece above the slots, steadied by small staples, so that it may be withdrawn. On this the upper pulleys run. The wire shields ⌐¬ above these slots are to prevent the bedclothes from resting upon the rollers.

The pulleys or wheels are fastened in the rubber tubes by making a few turns of copper wire around the iron screw of the pulley. This is pushed into the tube and bound outside with fine wire.



Rings of rope large enough to pass over the foot are then put through the lower pulleys. If these rings open, or the foot is slipped out of them, the leg is taken down without any of the apparatus about it; and the large wire may be withdrawn, and the leg lowered with the pulleys and rings still attached.

The material used costs only about seventy-five cents, and can all be bought *ready for use*. An evening is abundant time to construct the whole apparatus. The longitudinal motion is the same used in Salter's bed-cradle, having, however the advantage that the whole bed is left free with nothing to inconvenience the other limb. Besides, there is no tilting sideways, which we always have when a cradle stands on a mattress. But most important, and what I have never seen used before, is the arrangement to *rotate* the limb freely, and allow patient to turn on either side without jarring the broken member. My patient was able to rotate three-quarters of a circle, touching his toes on either side. He slept on his side and never had even a tired back, much less a bed-sore, though he was not permitted to sit up for nearly five weeks. This apparatus was a gradual improvement from suspension with bandage and rubber straps. It has answered its purpose so well that though more than two months have now elapsed since the injury, and union is getting quite firm, the patient, who has been sitting up for the last two weeks, still insists that he must have his leg suspended in it at night if he is to sleep soundly, his motion and turning in sleep never producing pain enough to waken him.

I hope that other surgeons may find this simple and cheap little piece of apparatus as useful as I have. Success often depends on such *comparatively* unimportant things.

STRANGULATED FEMORAL HERNIA. OPERATION BY TAXIS.

DEATH IN 67 HOURS FROM RUPTURE OF THE BOWEL.

By THOMAS E. SATTERTHWAITE, M.D.,

PATHOLOGIST TO ST. LUKE'S AND THE PRESBYTERIAN HOSPITALS.

The following case is of interest, as it illustrates a rare affection of the bowel, and one which may be the cause of failure when the operation by taxis is performed.

Anne Lewis, aged 25, born in Ireland, single, had been complaining of abdominal pain and constipation for some months. On the 11th of July last, after two days of more than usual suffering, she took a dose of salts, but was unable to retain it on her stomach. Finding herself getting gradually worse, and becoming alarmed, she sent for a physician. I saw her first about 5 P.M. She then complained of distressing pains over her abdomen and in the left groin, where she said there was an inflamed gland such as she had once had on her neck. This trouble in her groin had annoyed her before, but had always been relieved on lying down. Now, however, it had persisted, and the pain had become so severe that she had used poultices. She had vomited nothing but the medicine.

Her countenance was anxious, respiration hurried, pulse about 75 and irritable, surface cool.

Examination showed on the left side a femoral hernia about the size of an English walnut. There was one prominent swelling, and close by and to the inner side were two smaller ones, separated by what seemed to be a constricting band. There was no tympanites nor unusual sensitiveness of the abdomen on pressure, though, in the tumor, the sensitiveness was marked. No effort at reduction was made at this time.

After consultation with Dr. Gurdon Buck, the patient was removed to St. Luke's Hospital and taxis was performed under ether $2\frac{1}{2}$ hours after she was first seen. No difficulty was met with in effecting reduction; in fact, the entire mass yielded to a very gentle pressure, slipping away from beneath the fingers. The femoral canal was left quite free, so that the finger introduced in it met with no resisting body.

Partial relief followed the operation, but the pain continued and vomiting commenced the next day. On the same day some tympanitic distention of the abdominal walls showed itself, and the bowels remained unopened; on the third day some abatement in the unfavorable symptoms took place, and under the opiates given the respiration and pulse fell to nearly the normal standard. The bowels were still unopened. Opiates were given freely and at regular intervals. The same evening the temperature and pulse rose very rapidly, though the respiration remained as before.

The patient died on the following day.

Autopsy 22 hours after death.—There was great tympanitic distention of the abdomen. The bowels were found somewhat congested. In many places the coils were attached to one another and to the omentum by slight and newly formed adhesions. There was a general deposit of plastic material over the anterior surface of the peritoneum, and fæco-purulent fluid was

found throughout the peritoneal cavity. At the orifice of the left femoral canal there was found a knuckle of small intestine, partially attached to the upper edge of the opening. Above this point the intestine was very greatly distended, chiefly by gas. At one point in the mass fæco-purulent matter was discharging itself freely in a direction downwards and inwards, toward the floor of the pelvis. A narrow band was all that remained to unite the upper and lower portions. This point was about six feet above the ileo-cæcal valve.

From a point an inch below the rupture, and downwards for a distance of about three inches, the adjacent sides of the gut were crowded together and adherent. The confronting surfaces were pretty firmly united by plastic matter, but there was no appearance of twisting. On the exterior of the intestine there were collections of a firmer fibrinous tissue.

After removing this portion, with about six inches of the bowel above and below the rupture, water was poured from above downwards, and the obstruction was found to be so great that the stream which passed was only the size of a goose-quill.

Further examination showed that this obstruction was due to a double stricture, the upper one admitting only a No. 8 urethral bougie, and the lower one the little finger. Between these two points the intestine was dilated for a length of about an inch and a half, and was empty and of a dusky color.

At the seats of stricture were found small rounded or oval elevations; these were on the inner surface, and opposite to the attachment of the mesentery.

Subsequent microscopic examination showed them to be solitary glands undergoing degeneration. In one instance a cheesy deposit was found in one of these. In general, the glandular epithelium was so changed as to leave some doubt of its true character; still, the reticular framework of the follicles was, as a rule, demonstrable. Both the submucous and muscular coats were somewhat hypertrophied, and the latter was studded with lymphoid cells.

In the works that have been within my reach, I have only met with three cases that are at all similar. Two of them were originally published in the Pathological Transactions of London. Both of them were strictures of the small intestine. In each of these instances the walls of the gut were very much thickened, and the calibre so much diminished as only to admit the tip of the little finger. The first case was associated with cicatrizing ulcers about the strictures; in the second case the strictured portion had evidently formed part of the contents of an old hernial sac, into which it had frequently passed. The third case is alluded to by Rokitansky when he speaks of "a fatal case of constipation where a portion of the ileum, 24 inches in length, was found enclosed in a cartilaginous sheath of peritoneum 4 inches long;" and he adds that "extensive adhesions among the coils or portions of the mesentery often affect the small intestine so as to produce external valvular duplicatures of the intestinal coats at the projecting angles," and that "this form of adhesion is not infrequently developed in intestinal segments which have long been included in large hernial sacs."*

These two last cases resemble the present one in the fact that the stricture is associated with an old reducible hernia; and the last case has the further point of resemblance, viz., that the coats were united externally by fibrous matter. The thickening of the intestinal walls in such cases is usually excessive, while in this case it was moderate in amount. I learned nothing from her previous history to incline me to the idea that her trouble was congenital.

FOUR CASES OF IMPERFORATE ANUS OCCURRING IN THE MALE INFANT,

IN THE PRACTICE OF

SAMUEL S. THORN, M.D.,

TOLEDO, OHIO.

Case I. On Saturday evening, Jan. 2, 1869, I was called upon by Dr. J. G. Nolen, of this city, to see with him a child in his practice with imperforate anus. The child, a vigorous one, was born on the morning of Jan. 1, 1869, of a strong, healthy German woman, the mother of three other living children all well formed. Upon examining the perineum I found the raphe, from coccyx to scrotum, well defined and continuous. At the natural seat of the anus was a depression of dark blue color, and in shape resembling the umbilicus of a child a month or more of age; from its color I expected to find the extremity of the intestine close at hand. To the touch the tubercle was lax and movable, but beneath this all was firm and resisting under pressure. There being no other alternative, the consent of the parents obtained, we proceeded immediately to operate. The child was placed in the position for lithotomy, upon the lap of Dr. N., the feet drawn well up over the abdomen. Upon examining the penis preparatory to the introduction of a catheter, there was evidence of a connection between the urethra and rectum. The nurse being questioned, stated that with each discharge of urine there was a slight discharge of dark matter resembling meconium. This statement deterred me from introducing the catheter. An incision was now made along the raphe through the tubercle one and one-half inches in length, and carefully extended upwards and backwards, following the curvature of the sacrum to the depth of two and one-half inches, or as high up as the finger could reach. At this depth, the resistance being less firm, I introduced a long, narrow exploring trocar and canula and thrust it upwards, easily overcoming the little resistance; the withdrawal of the trocar was followed by a small discharge of dark-colored meconium. The entrance to the intestine was easily reached and enlarged by means of a long blunt bistoury, and this being accomplished, we were gratified by the appearance of a full and free evacuation of meconium, fæcal matter, and gas. After cleansing the wound an oiled tent was introduced, and the patient placed in its mother's arms for the night. Anæsthetics were not used during the operation.

Jan. 3. Patient passed a comfortable night, and in the early morning pulled vigorously at the breasts. On removing the tent, there followed a full evacuation of fæcal matter. Wound looked well. With each discharge of urine there was found a trace of fæcal matter. A large-sized flexible catheter was now introduced into the wound and firmly secured. The nurse was instructed to remove the same as often as every six hours.

Jan. 4. Child comfortable, evacuations free; traces of fæcal matter still appearing, ordered continuation of catheter as before.

Jan. 5. Child doing well; edges of wound healthy; little or no redness surrounding.

Jan. 7. All things appearing well, treatment was continued.

Jan. 10. General condition of patient good; evacuations natural in quantity, but not as free as at first.

Jan. 11. Since last visit, by the assistance of Dr. C. H. Harroun, a very skilful dentist of this city, I have perfected a conical-shaped bougie from dental rubber partly vulcanized, in length 5½ inches, in diameter at the point $\frac{3}{16}$ inch, at the base $\frac{5}{8}$ inch. This rubber instrument being only about half vulcanized, has a smooth surface and is very flexible; at this visit this instrument was introduced about ⅔ its length, but not without causing considerable pain and straining. I secured the bougie in position, and instructed the nurse to remove it after a few hours, to permit an evacuation, and then to replace it.

Jan. 14. The passage to the rectum is now well open; patient doing well; ordered only occasional application of bougie.

Jan. 25. All traces of fæcal matter in the urine have disappeared; in fact none has been seen in the last week. I now considered the patient in a safe condition, and after ordering two applications of the bougie every 24 hours, withdrew, promising an occasional visit to the child.

March 1. Saw patient this morning, and found him well and much grown; discharges from the bowel natural in appearance, regular and passed without pain; advised occasional application of instrument.

Nov. 12, 1872. Patient thriving, and is in all respects equal to children of his age; has no trouble either in retaining or passing fæces from rectum, the sphincter being in full force and action. At the date of operation no attempt was made to draw down the intestinal mucous membrane to secure attachment to the integument. The artificial passage now appears well lined with the natural membrane.

Case II. I saw, Jan. 26, 1869, at the instance of Dr. H. N. Schuetzer, a child born in his practice with imperforate anus. Child small and feeble, weighing about four lbs. This child too was of German parentage, born on the afternoon of Jan. 25, and operated upon on the morning of the 26th. To appearance, locally, this case did not differ materially from the first case, except that there was not present the navel-shaped tubercle. Operation similar to that upon No 1, without aid of anæsthetics or application of catheter; cutting was carried up to full length of finger, well pressed up, but without reaching the gut; and there being no change in the resistance or any feel of fluctuation, the prospects of successful termination in this direction doubtful, it was decided to make a statement of the condition of affairs to the parents. This explanation brought out the fact, that since the birth of the child it had steadily refused to take anything into its stomach, and that with this refusal there was apparent an inability to do so. An examination of the mouth and fauces did not, however, indicate any obstruction. I then suggested an opening into the descending colon through the inguinal region, but the prompt refusal of the parent prevented further effort.

Jan. 27. Child died about 10 A. M. Autopsy showed the rectum entirely absent, the colon floating with its extremity pointing towards abdominal walls, and to the right. An exploration of the œsophagus satisfied me of the existence of an obstruction or constriction. With this condition existing no successful termination could have been expected.

Case III. Child born Sept. 16, 1872, 10. A.M., in the practice of Dr. S. H. Bergen, of this city, and seen by me Sept. 17, twenty-four hours after birth. The appearance and touch of perinæum in no way differed from Nos. 1 and 2 except absence of navel-shaped tubercle mentioned in No 1. Raphe well defined; perinæum firm and unyielding. The child was held by Dr. B. Operation performed without anæsthetics or the introduction of catheter into urethra; success in my first case deciding me on this point, though fæcal matter was not found present with discharge from urethra, as before. The cutting was similar to that in Nos. 1 and 2, and extended to full length of finger well pressed up as in first case. At this depth resistance was diminished and I decided to try the sharp bistoury, and by thrusting it upwards and backwards felt all resistance disappear. Upon withdrawal I was gratified by finding a trace of meconium; wound enlarged antero-posteriorly, a large-sized elastic catheter introduced, and patient placed in bed with its mother.

Sept. 18. Patient comfortable, but not getting any nourishment; passage small; continue use of catheter.

Sept. 19. Child still refuses to nurse, and, contrary to my directions, is fed with sugar water and bits of thin cracker. Evacuations very small. Edges of wound slightly inflamed. Scrotum fully distended and red. Gave child an enema: warm water ℥ ij., which was retained. Ordered nurse to introduce catheter two or three times in next 24 hours.

Sept. 20. Patient comfortable; has had two full evacuations, and has nursed a little, but gets its main support from the sugar-water and crackers. Continued catheter as before, and urged nurse to discontinue sugar-water.

Sept. 21. Patient comfortable, evacuations natural, scrotum reduced to natural size and color, edges of wound looking well.

Sept. 22 and 23. Patient doing well. C. T.

Sept. 24. Patient not as well as yesterday; evacuations frequent and quite offensive. Ordered hydrarg. ch. mite, gr j.; opii et ipecac. āā. gr. ½; misce in ch. No. vj.; div. et sig. one powder every four hours, and to rest from application of catheter.

Sept. 25. Patient's condition still bad; continue powders; ordered sodæ bicarb.; again urged nurse to give up the sugar-water and crackers and to rely upon the mother's milk, of which she had an abundance.

Sept. 26. Case apparently without hope. Nurse persists in the use of the sugar-water. Entero-colitis fully developed.

Sept. 27. Child died. No autopsy.

Just how much the feeding of the child had to do with its death I am unable to state. I was strongly impressed, however, with the feeling that to the family the death of the child would be a welcome termination of the case.

Case IV. This child, of Irish parents like the first, was born in the practice of Dr. J. G. Nolen, Friday morning, Oct. 4, 1872, and seen by me late on Saturday evening, Oct. 5, 36 hours after birth. Raphe of perinæum well defined; the locus naturæ showed two or three small points or openings upon a dimple. These openings, however, were not skin deep. To the touch the resistance was not like that found in the other cases. From the elasticity of the parts I looked for the close proximity of the gut; upon cutting I was not disappointed. The incision did not exceed one inch in length. The gut was reached at or about an inch in depth. Before visiting this child the parents had given it three doses of castor-oil, to force, as they said, a passage. As soon as the rectum was opened there was a full and very offensive discharge of meconium and gas.

Oct. 6. Child had a good night, except that evacuations were frequent. Ordered: Pulv. ipecac, pulv. opii āā gr. ¼; sodæ bicarb. gr. xij. M. in ch. vj.; div. et sig. one powder every four hours.

Oct. 8. Child doing well; evacuations not as frequent.

Oct. 10. Patient continues to improve; but three or

four evacuations in 24 hours. Continued powders every six hours.

Oct. 25. Patient doing finely; edges of wound healed. Anus presents a natural appearance.

Nov. 27. Child continues well and thriving.

Original Lectures.

ON ACUTE ARTICULAR RHEUMATISM.

A LECTURE DELIVERED AT BELLEVUE HOSPITAL.

By AUSTIN FLINT, M.D.,

PROF. PRACTICAL MEDICINE, ETC.

[Reported Phonographically for the RECORD.]

GENTLEMEN:—My remarks to-day will be upon the subject of acute articular rheumatism, and they will be based upon the history of this man's case who is now before us. His name is P., æt. 22, Norwegian, and by occupation a blacksmith. To-day is the tenth day of his disease. I may here remark, that this disease, especially in its acute form, is not very frequently seen in this hospital. The present case does not show the disease in its acute form, for the patient is apparently approaching convalescence, yet it will serve to illustrate some of the important points pertaining to this disease. The word rheumatism is a term which has been used with a good deal of latitude, and under this name several different affections have been taken in, such as certain neuralgic troubles, certain affections of the muscles, and certain affections of the joints. When, however, we use the term articular rheumatism, we refer to a very distinct and clearly defined affection. It is a constitutional affection, characterized by local manifestations consisting in an inflammation generally affecting several joints of the body, and not infrequently fibrous structures elsewhere than in the joints. It is an affection which usually attacks the greater part of the joints of the body, and these articular affections are but the local manifestations of the constitutional disease. These local affections are in certain points distinguishable from ordinary inflammation of analogous structures. We have no suppuration, none of the inflammatory products, no production of new tissue, which we might expect in ordinary inflammation, and these are essential points of difference which characterize these local manifestations of articular rheumatism. Another point which is very striking is, the inflammatory condition frequently subsides and disappears in a very short time; one day it is present, and the next day perhaps it may be entirely gone. The occurrence of these local manifestations in different joints successively is also a striking feature of the disease, as one joint may be affected to-day, and another to-morrow. Another feature which goes to show its constitutional character, and establish what has been said with regard to the local manifestations is, the joints are affected symmetrically. The law of parallelism is strikingly illustrated in this disease; corresponding joints on both sides of the body are affected, and it is seldom that the strict law of symmetry is violated. If the joints upon both sides of the body are not affected, it does not violate the law, but it is simply the fact that the law is not illustrated. If corresponding joints are not affected, analogous ones are affected, such as the wrist and ankle perhaps, but an affection of the wrist and knee joint upon different sides of the body is rarely seen. This man is 22 years of age, which illustrates the fact that rheumatism, primarily, affects young subjects. A person, however, who has had the disease in early life, will be subject to repetitions of attacks ever afterwards, thus showing a constitutional tendency. Acute articular rheumatism also belongs among those diseases which are inherited, or rather, to which a predisposition may be transmitted. This man has generally had good health, and this is the first attack of the disease he has ever had. He was attacked in the day-time. It is more frequently the case that the patient is attacked in the night-time. The disease generally attacks suddenly, yet in a certain number of cases, the acute attack is preceded by more or less soreness and tenderness about the joints. As we look at the history of this case, we see that for two or three weeks this man had felt soreness in the joints, but not sufficient to prevent him from continuing in his occupation. The first manifestations which he had were in the smaller joints of the hands and feet; the carpal and metacarpal and tarsal and metatarsal joints. It first appeared in the right hand, then in the left foot; then in both knee-joints; then both wrists; then both shoulder-joints; and then in both hip-joints. The law of parallelism, it will be seen, was very well illustrated. At the present time the joints are comparatively but little affected. I deem it hardly necessary to dwell at any length upon the local symptoms, such as the pain and swelling which accompany the local manifestations; and will dismiss them with the simple remark, that we do not usually have much swelling and erythematous flush about the larger joints such as the hips and shoulders. I must now ask you to mark the statement which I am about to make, as it is of special importance in connection with the topic I shall presently mention. The statement is this: this man has had no pain at any time on the chest, no præcordial pain at any time during the course of the disease. I will soon speak more particularly of the importance of this statement in the history of his case. This is a disease which in its acute form—for it is presented to us both as an acute and sub-acute affection—is characterized by a good deal of febrile movement pertaining to the disease itself, and also symptomatic. One of the popular names for this form of fever is "rheumatic fever," and it is not altogether improper, for the fever does not depend upon the local affection entirely, but it is sometimes altogether out of proportion to the local affection. We have, therefore, a fever which is partly essential and partly symptomatic. Last evening this man's pulse had fallen to 72 and the temperature in the axilla was 100¼. This affords a good illustration of the disparity which is sometimes seen between the pulse and temperature, as regards the criteria of a fever. When such a disparity is present, the temperature is entitled to the preference in deciding the question of fever or no fever.

This morning the pulse was 68. It is always to be borne in mind, that, in many diseases, about the time of convalescence, the patients have a pulse which is below the average frequency in the same persons in health. This is the case in typhoid and typhus fever, pneumonia, and some other affections. This morning there is no fever present, the temperature being 98¾.

This man has been taking quinine and nitro-muriatic acid. It might, at first, strike the mind as an incongruity in the treatment of this disease to administer an acid, while the predominant feature of the disease is the presence already of an acid in the system, but really there is no incongruity in it. Over and over again we apply remedies and measures which are di-

rectly antagonistical, and each will meet its own indication, and often the only proper method of treating certain cases is to meet the indications.

We come now to speak of one of the important events which is liable to occur in the course of inflammatory rheumatism. This disease in itself, as far as the constitutional difficulty is concerned, is not dangerous to life; but there is a danger in connection with certain incidental events, and those events which are most likely to occur relate to the heart. There is a special liability to an inflammation affecting one or both serous investments of this organ, and these are the untoward events to be looked after in cases of articular rheumatism. The importance of the disease and the permanent welfare relate chiefly to the occurrence of these complications. There are some other complications which are so infrequent that they do not give us much care, and we will pass their consideration. The cardiac affections are the prominent ones. Endocarditis occurs in quite a proportion of cases, but I do not give you the figures, because I think there has been some looseness and error in making up statistics upon this point. The reason for this I will soon mention. Pericarditis is of much less frequent occurrence than endocarditis, and it may be said further with regard to these complications, that if we have pericarditis we have endocarditis, but the rule does not hold in the opposite direction. Pericarditis involves a certain amount of immediate danger, though a great proportion of cases get well. What we probably have in this case is endocarditis, and first of all we will study the evidence upon which this probability is based. The evidence in this case is not absolute, but it is *probable*. Now you will recollect the fact to which I called your special attention a few moments ago, *viz.*, this patient has not had præcordial pain, or any chest symptoms whatever, during the progress of his case. The diagnosis of endocarditis is therefore based entirely upon physical evidence. This is the reason why endocarditis is a disease which has been discovered within the last half century, and was never before known. It was discovered by physical exploration, and must continue to be recognized by this means, because it occurs without any subjective symptoms. It is associated probably with some increase of the circulation, but as this increase goes more or less with the rheumatism, we cannot draw the inference from this that endocarditis is present. How are we to determine whether a patient has endocarditis or not, who is suffering with articular rheumatism? We are to reach a positive diagnosis in this way: if the patient be under your observation, and you can determine by auscultation that there is no mitral systolic murmur present at the commencement of the attack, and then in the course of the disease a mitral systolic murmur is developed, you know that the patient has endocarditis. It all depends upon the development of this mitral systolic murmur, and the murmur is the hinging point. This patient has a mitral systolic murmur, but the diagnosis is not positive, because the patient had the same murmur when he came into the hospital, and we do not know certainly that the murmur has been developed since the commencement of the disease. It has probably been developed in this patient since the commencement of this attack, for it is the first attack the patient has had of the rheumatism; he has always been well, and as the murmur is one which does not indicate regurgitation, it is altogether probable that in this case it is evidence of endocarditis. I find here that the apex of the heart is beating in the fourth intercostal space, as it not infrequently does when the body is in a recumbent position. By percussion I determine that the heart is not enlarged. This would not be the case if the patient had had mitral disease for any length of time previous to the present attack, for he would have more or less enlargement of the heart.

Within a certain circumscribed space about the apex of the heart, I get a murmur with the first sound of the heart, a mitral systolic murmur, and it is not propagated much beyond this quite limited area. It is not proper to call this murmur a mitral regurgitant murmur, because there is no evidence of regurgitation.

What do we look for as physical evidence to show that there is regurgitation? The fact that a mitral murmur is present, is not limited to the apex, is tolerably loud, and is propagated to the left, would be evidence that it was one of regurgitation.

I also get a murmur at the base of the heart, but I attach no special importance to this, because we cannot attach much importance to a murmur at the base of the heart in a case of articular rheumatism. It is very frequently present, and is dependent upon the condition of the blood. It is always present in females, or at least, I believe I have never seen a case of articular rheumatism in a female where this murmur was not present. It is just here I apprehend that a great confusion has arisen with regard to statistics in reference to endocarditis, and many cases have been called endocarditis in which the disease did not exist. I would not make my diagnosis relying upon this murmur at the base, unless I had the mitral systolic murmur at the same time.

Endocarditis is a serious complication, because in it the rheumatism has laid the foundation for the subsequent occurrence of valvular lesions.

We have attenuation of the valves, thickening and calcification of the valves and other valvular lesions, all arising from an endocarditis in connection with rheumatism, and we have not much knowledge of endocarditis except in connection with these cases of articular rheumatism. We come now to ask the question, what are the indications in the treatment of acute articular rheumatism? In the first place we would like to cut it completely short if possible, but we cannot do this often, if ever. Next, we would like to abridge its duration, and there is reason to believe that this may be done to a certain extent. The great object, however, is to prevent these cardiac complications, pericarditis and endocarditis, for if a patient passes through this disease, and escapes these complications, he is exceedingly fortunate.

Just here, however, a knowledge of the natural history of the disease, based upon the observation of cases which have been permitted to run their course without the influence of therapeutical interference, is of value in making up our estimate of the value of treatment. In the year 1862 I conceived a plan of observing cases of articular rheumatism, without the use of medicine. The reason for so doing was because almost all the cases reported as having been under the influence of any special plan of treatment, such as mercurialization, colchicum, bleeding, blistering, &c., were reported as cured, and hence each plan of treatment was reported as being attended with the greatest success. I therefore reasoned that the probability was, inasmuch as all the different modes of treatment tended to success, that the disease itself tended towards getting well. I accordingly treated 13 cases in this hospital, and they got no remedy at all, except one which was intended for a moral effect upon the patients, and that, for the sake of giving it a name, was called the placeboic remedy. The only treatment which these patients received, aside from this placeboic remedy, was

a little anodyne and local applications to the joints of a palliative character. I resolved to continue the plan of treatment until something occurred to render it improper to continue it longer, and in only one of the 13 cases treated after this method did any complication occur, and that patient had the complication when she came into the hospital. The average duration of the disease in those cases was 26 days, and no important complications took place. I reported these cases in an article entitled "A Contribution toward the Natural History of Articular Rheumatism," which was published in the *American Journal of the Medical Sciences*, July, 1863. I hope I shall not be thought egotistical in referring to these observations. They were made in this hospital, and my object in making them was stated to the class then in attendance. So far as I know, a series of similar observations had never before been made. I am led to assert my claim to whatever credit may belong to precedence in this line of investigation, because shortly after my observations a similar plan for the same object was pursued by others. Guy's Hospital Reports, volume for 1865, contains a report of a considerable number of cases treated by Dr. Gull, chiefly with mint water; and another report of additional cases was made in an article by Dr. Gull and Dr. Sutton, contained in the "Transactions of the Royal Medical and Chirurgical Society of London," in 1869. I should not thus expose myself to the charge of egotism in asserting my claim to priority in the study of the natural history of articular rheumatism, had these observers made any reference to my article in the *American Journal of the Medical Sciences*. I feel bound to make this claim, not alone for myself, but for this hospital and for American clinical medicine.

Dr. Fuller, who is the author of the so-called "Alkaline treatment," states that cardiac complications will not arise after the alkalescence of the urine is once established, but I think this author is too ardent in his statements, for I have seen cases in which endocarditis has been developed while the patients were fully under the effect of the alkaline treatment. Statistics, however, show that there is a diminished *liability* to these complications, and therefore we are not warranted in repeating observations without remedies. The method of treatment to be pursued in a case of acute articular rheumatism, is the adoption of what is called the alkaline treatment. The prime object in this treatment is, to produce alkalinity of the urine, regarding that as the criterion that the system is sufficiently affected, in as short time as possible, for we cannot tell at what instant the complications may appear. To accomplish this the bi-carbonate of soda or potassa may be given in half-drachm or drachm doses every two hours, and by these doses you can render the urine alkaline within twenty-four hours at the farthest, with a good deal of certainty. After the urine has been rendered alkaline, the remedy is to be continued in varying doses sufficient to maintain the urine in an alkaline condition during the continuance of the disease. In this case before us, the disease has continued only ten days, and the patient is apparently convalescent.

Quinia in full doses also forms a good adjuvant in the treatment, as the patient is becoming convalescent. It contributes very much to the welfare of the patient. The joints are to be treated by palliating applications. Frequently you will find that shampooing the joints, be they never so tender, is very beneficial, commencing with gentle frictions, and gradually increasing the force as the patient can bear. Fomentations which contain alkalies and anodynes may be used also as local applications. As a rule, it is one of the great objects of medical treatment to relieve pain, for pain interferes with sleep and wears out the vital forces of the patient. Those patients afflicted with articular rheumatism may have opium sufficient to allay all irritation from pain, and give them quiet and rest. A more minute detail of the pathology of this disease must be considered at another time.

NOTE.—At a subsequent clinical lecture Dr. Flint presented a case of acute articular rheumatism during the course of which peri-endocarditis (developed when the urine was alkaline), chorea, and right hemiplegia from embolism occurred. Coincident with the occurrence of the hemiplegia, a basic systolic heart-murmur, which had previously existed, disappeared.

Progress of Medical Science.

WARM SALT BATHS IN INFANTILE FEVERS.—The difficulties which attend the use of cold baths, when it is desirable to reduce the temperature in very young children, has led Schwalbe, of Zurich, to try warm baths. His patient was a delicate rachitic child suffering from catarrhal pneumonia, and but little over a year old.

The baths contained from 3 to 5 per cent. of common salt, and were given at a temperature varying between 86° and 88° Fahrenheit. At first they were employed from once to three times daily. The child made a good recovery. Many months after a similar attack occurred, and the same treatment was adopted, with the exception only, that the baths were more frequently repeated. The child made a favorable recovery the second time. It was observed that after each bath the temperature of the body was reduced from 2 to 4 degrees.—*Memorabilien*, 1872.

POISONOUS DOSES OF CHLORAL.—The smallest dose which has produced poisoning is 2½ scruples, while 460 grains have been taken without unpleasant consequences. The symptoms are diminished frequency of respiration, redness of the conjunctiva, contraction of the pupils, lividity of the lips, and falling of the jaw. The character of the pulse has not been found to be uniform. The treatment should consist in: 1. Removing the poisonous matter or diluting it by water, tea, coffee, or other fluids; and 2. Restoring respiration. Too much reliance must not be put upon so-called antidotes, such as strychnine, physostigmine, morphine, camphorated ether and ammonia. These remedies cannot always be trusted. Possibly transfusion of blood, which has been successful in cases of poisoning by chloroform, may also prove useful in these cases.—*Med. Chir. Rundschau*, Oct., 1871.

THREE RESECTIONS OF THE ANKLE-JOINT.—Albanese, of Palermo, has published three cases in which he has performed this operation. He makes a single curved incision over the outer malleolus; the bone is removed, leaving both the periosteum and capsule of the joint entire. Two of the cases made a good recovery; the third healed, leaving a fistulous opening. Subsequently extensive caries was developed, and amputation was resorted to. In each instance the malleoli were almost completely re-formed, though they had been entirely removed. There was no bony anchylosis, but a moderate amount of motion in the joint.—*Med. Chir. Rundschau*, Nov., 1872.

FUMING NITRIC ACID FOR INTERNAL PILES.—Billroth records 26 cases of prolapsing piles treated by him in various ways. In four instances he applied the

actual cautery, in ten the galvano-cautery, and in the remainder fuming nitric acid. The latter plan was pursued as recommended by Dr. Houston, of Dublin. The results proved eminently satisfactory. His mode of proceeding was as follows: A free evacuation of the bowels was obtained by means of castor-oil given the day previously. Before the operation the mass was brought down by an injection. The patient was then placed on the side with the knees flexed. The parts adjacent to the anus were first well protected by oil so that no injury should be done them. A small piece of wood was then dipped in the acid and applied to the outside of the swollen mass, until it had become tolerably stiff and had assumed a yellowish-green color. It was then smeared with some simple form of ointment and returned within the sphincter. The operation was usually performed without an anæsthetic, and an opiate suppository was rarely given afterwards. It is proper to keep the patient in bed. Fever rarely follows, though retention of urine is not uncommon for the first few days. The eschar usually separates without loss of blood. It is proper to give castor-oil on the third or fourth day, provided no fæces have passed. Hemorrhage will be likely to occur if the fæces become hardened; such accidents, however, are readily controlled by ice. Of the patients treated in this way some were discharged on the 5th and 9th days, though severe cases were under treatment from six to eight weeks. Several of the patients were examined a year after the operation, and there was no stricture in any one of them.

Billroth believes that in very severe cases this treatment may fail, and then suggests the use of the acid nitrate of mercury, as recommended by Curling.—*Wiener Med. Wochenschrift*, No. 35, 1871.

Embolism in Endocarditis.—The following statistics have been compiled from the records of the Pathological Institute in Berlin. They are the results of autopsical examinations in 300 cases of endocarditis that were observed between the years 1868 and 1871. The lesions were confined to the valves in nearly every instance; disease of the parietal endocardium occurred only once. The affection was limited to the right side in 1 per cent. of the cases, in 9 per cent. it was associated with similar trouble on the left side. In 10 per cent. the left valves were the only ones diseased, but in 89 per cent. the right valves were also affected. The following facts were also ascertained:

The tricuspid was diseased alone in 1 per cent. of the cases, and with others in 10 per cent. The pulmonary was not diseased alone, but in 1 per cent. with other valves. The mitral was alone affected in 52 per cent., with others in 85 per cent.; the aorta alone in 13 per cent., with others in 43 per cent.; 29 per cent. of all the cases were complicated with emboli. In 2 or 3 per cent. of these the trouble originated in the right side of the heart and produced infarctions and abscesses in the lungs, chiefly in the lower lobes.

In 26 per cent. the emboli were derived from the aortic circulation. In the 76 cases of this nature, the mitral was affected in 87 per cent., and the aorta in 49 per cent. The following is the ratio of relative frequency with which emboli occur in three different organs: In the kidneys in 75 per cent.; in the spleen in 51 per cent.; in the brain in 20 per cent.; in the intestinal tract and in the liver in 7 per cent.; in the skin in 5 per cent.; in the medulla in 3 per cent.; and less often in the thyroid gland and eye.—*Med. Chir. Rundschau.*

A New Nasal Speculum.—Wimmer, of Dresden, claims to have invented a new instrument of this kind, which he believes has certain advantages over any other now in use. It is, in fact, merely a modification of the ordinary wire speculum for the eye. Instead, however, of having extremely short arms, it has very long ones, and in addition is provided with an adjusting screw to regulate the amount of distention in the spring. It is self-sustaining, dilates the nares very completely, does not touch the sensitive septum, and is extremely simple in its mechanism. In introducing it, the spring is to be compressed by the finger and a single arm is to be passed into each nostril.

On removing the pressure from the spring the arms will spread widely apart and hold the alæ well distended. The adjusting screw, by regulating the amount of distention, will render the instrument available for smaller or larger cavities. Wimmer further states that the instrument remains firmly in place and causes little or no inconvenience. Both hands are free, and by the aid of the aural or laryngoscopic mirror, the parts can be thoroughly inspected and operations can be performed with greater ease and precision.—*Algemein. Med. Central. Zeitung*, Dec., 1872.

Injections into the Brain Substance.—H. Nothnagel (*Centralblatt*, No. 45, 1872) gives a method by which the functions of various parts of the brain may be studied. It consists of injecting a concentrated solution of chromic acid through a small hole in the skull, by means of a subcutaneous syringe. The part injected becomes green and hard, and surrounded by partial encephalitis. The function of the part is completely destroyed, while the lesion is exactly circumscribed. Nothnagel has made over a hundred experiments, the animals living from eight to fourteen days. He promises to publish his results soon.

Influence of Belladonna on Sweating.—In some interesting communications to *The Practitioner*, Dr. Sidney Ringer brings forward an abundance of evidence to prove that belladonna and its active principle are able to check and prevent sweating, whether the result of disease or induced by exposure to an elevated temperature. In the former case his observations enabled him to conclude that one two-hundreth of a grain of atropia injected under the skin is generally sufficient to check sweating for one night. This dose produces dryness of the fauces, but does not dilate the pupils. Stramonium, it was found, is able to exert the same influence.

Hyosciamia.—Dr. Oulmont, Physician to the Hôtel Dieu, Paris, has published recently in the *Bulletin de Thérapeutique* the very interesting results of experiments with this principle, which possesses the active principle of the drug and is very much more reliable as an agent. He found that the effects produced by hyoscyamus itself not only varied with the dose employed, but even with equal doses according to the mode of preparation; the part of the plant used, and even with the season of gathering, the mode of drying, etc., etc. Sometimes with very feeble doses he got symptoms of poisoning; on other occasions large doses produced no results. In his experiments on patients with the alkaloid he always used the commercial hyoscyamia known as mereko, which is a brownish syrupy liquid. It was always administered either in pills containing one fifty-fourth grain (one milligramme) or in hypodermic injections of aqueous solutions, varying from 1 to 4 per cent. strength.

The result of physiological experiments were:

1. Hyoscyamia has a manifest action on the circulation; in small doses it diminishes it, in large doses it

paralyses it. All the general phenomena are due to modifications of the capillary circulation, and disappear rapidly, the drug being eliminated very quickly.

2. Hyoscyamia has no action on the nervous system of the life of relation; the sensibility is not modified; nevertheless it is weakened by large doses.

Dr. Oulmont insists upon the fact that it does not directly act on sensibility. In an animal which has taken large doses, neither the mixed nor the sensitive nerves, the posterior roots in the cord, nor the posterior columns can be irritated without extreme pain.

This experimental fact appears to contradict clinical observation, which proves the happy effect of hyoscyamia upon pain, particularly neuralgia.

A *resumé* of the effects of hyoscyamia when used for the relief of disease are given as follows:

1. Hyoscyamia represents all the active principles of hyoscyamus. The fixity of its composition gives to the results which are obtained from its use a precision which hyoscyamus in substance does not yield in the same degree.

2. Hyoscyamia should be given at first in weak doses (one thirty-two grain daily), either in pills or by hypodermic injection. The dose may be gradually increased to five or six times this quantity.

3. The remedy must be continued even if there are slight symptoms of poisoning, such as dryness of the throat and dilated pupils. But if the symptoms become grave, it must be suspended, and the symptoms being temporary, will disappear in a few hours.

4. Hyoscyamia exerts a favorable action in spasmodic and convulsive neuroses. It cured mercurial trembling in cases where every other remedy had failed. It produced a notable improvement in senile tremor and paralysis agitans.

5. Its action in locomotor ataxy was null.

6. In traumatic tetanus, although the patient died, this remedy produced a sufficiently notable remission of the symptoms to leave the question of its power still open and to call for new experimentation.

In-Fleshed Toe-Nail.—Dr. B. E. Cotting, Harvard (*Boston Medical and Surgical Journal*, January 2, 1873), gives a new operation for this painful and persistent affection, with illustrations, which consists in removing all the diseased parts, together with quite a large piece of the sound flesh, skin deep, from the side of the toe—sometimes making an open wound, say nearly an inch long by half or three-fourths of an inch wide. No portion of the nail need be removed; but if, in order to fully secure all the diseased flesh, overlapping or undergrowing, a segment of the nail is involved in the cut, no harm comes of it. The result, he states, is quite as good, perhaps better. By this operation, all the diseased parts are removed at once, and a clean, healthy wound substituted; to be treated as any other open freshly-cut wound, and to be allowed to heal as soon as possible by granulation. Generally, the healing is rapid, and without interruption. In the second place—and this is the principle on which success depends—as the comparatively large and superficial wound heals there is a contraction of the parts, and a drawing-in of the skin towards the centre from all sides, including that near the nail; so that when the wound is healed there is nothing left in the way for the nail to impinge upon its subsequent normal growth. The shape, also, of the toe itself is usually much improved by the operation.

Diarrhœa in Teething.—In a clinical lecture "On the Primary Dentition of Children," by Francis Minot, M.D., Harvard (*Boston Medical and Surgical Journal*, January 2, 1873), in speaking of the diarrhœa complicating teething during hot weather, recommends the common chalk mixture with the addition of one-fourth part of tincture of kino, which increases its astringency, and also keeps it from turning sour in hot weather. If the diarrhœa be not checked by this mixture, one drop of laudanum may be added to a dose, but not oftener than three times a day, in children under two years old. Diarrhœa is most apt to attack children who are brought up on the bottle; hence, if the case be urgent and do not yield to treatment, a wet-nurse should be procured if possible. When this cannot be done, he would strongly recommend the method of preparing the milk with arrow-root and gelatine, found in the treatise on "Diseases of Children," by Drs. Meigs and Pepper. Brandy is very useful to a teething child exhausted by diarrhœa, which should be given once in three or four hours, or oftener in urgent cases. The dose is ordinarily from five to twenty-five drops, given in milk; but if there be much prostration the physician need not fear to increase the amount.

The Horse Epidemic of October and November, 1872.—Albert Fricke, M.D., of Philadelphia (*Philadelphia Medical Times*, January 4, 1873), read a paper on this subject before the Biological and Microscopical Section of the Academy of Natural Sciences, with a statement of microscopical appearances of specimens, by Prof. Joseph Leidy, in which the results of the post-mortem examination, and those of the microscopic investigations of the lesions found in the nares, pharynx, glottis, larynx, and trachea, the presence of false membranes in the named parts, seemed to point to the conclusion that this disease is allied to the epidemics of diphtheria of the human family. The acute anæmia so generally observed is another proof of the diptheroid character of this epidemic. Out of thirty thousand horses owned in Philadelphia, over twenty-two hundred and fifty died in less than three weeks.

Amputation at the Knee-Joint.—John H. Brinton, M.D., surgeon to the Philadelphia hospital (*Philadelphia Medical Times*, December 28, 1872), in performing amputation at the knee-joint, always ties the popliteal vein. Whether a tendency to hemorrhage be owing to the firmness of the tissues by which the vein is surrounded, to its numerous branches, or, as Mr. Cardew has suggested, to the jar of the popliteal pulsation, he cannot tell, but certain it is, it is pretty sure to occur unless precautions are taken. He has yet to see the first evidence of trouble. In his cases the condyles of the femur were left untouched. Although there is but little difference in the mortality rate of the aggregate of cases, of all cases in which the condyles have been left, and of all those in which they have been removed in whole or in part, still that difference he states is in favor of the former method.

Fluid Extract of Castanea Vesca in Pertussis.—Thomas D. Davis, M.D., of Dayton, Ohio (*Philadelphia Medical Times*, December, 28, 1872), speaks of an epidemic of pertussis which broke out in the winter of 1870, while a resident physician in the Philadelphia Children's Asylum, in which the fluid extract of chestnut leaves was successfully used. This remedy was advocated before the American Pharmaceutical Association, in 1862, by Mr. George C. Close, of Brooklyn, N. Y. He has tabulated fifteen cases, so that there can be seen at a glance the number of paroxysms in each case while on the use of belladonna, without it, and the improvement for five days after using the other remedy. Dr. Davis says that Mr. Maisch, of Philadelphia, is the only druggist there who has reliable preparations of this article. The leaves are gathered from

July to October, the preference being given to those procured late in the season. The following is Mr. Maisch's formula for making the fluid extract: Chestnut leaves dried, cut, and bruised, sixteen ounces; glycerine, five ounces; sugar, eight ounces; and hot water, a sufficient quantity; the extract to measure sixteen fluid ounces. The dose is half a teaspoonful to a teaspoonful every three or four hours for a child six years old. In urging this remedy upon the notice of the profession, he does not claim for it a specific action, but thinks it will be found a valuable antispasmodic and expectorant, the preparations of which are not unpleasant, and are readily taken by children.

Antiseptic Injections and Drainage Tubes in Empyema.—Edmund Andrews, M.D., Professor of Surgery in Chicago Medical College (*The Medical Examiner*, December 15, 1872), noting the great success of carbolic acid injections in arresting the purulent secretion, and consequent exhaustion and hectic of large abscesses, he determined to try it in a case of empyema, in which the patient had been stabbed in the back part of the left chest. The wound was closed, but effusion occurred, which became purulent, and discharged through a fistulous orifice, remaining after the tapping of the cavity. The opening was so small and crooked that his first effort to inject carbolated water into the fistula was unsuccessful. He then anæsthetized the patient and made a good-sized opening into the chest between the ribs where the fistula lay, and about a quart of pus gushed out. A piece of small rubber-tube was inserted and tied in. Through this tube large injections of carbolated water, ten grains to the ounce, were freely thrown once a day. By this treatment the secretion of pus had been almost arrested; at the date of report, the patient was growing fat and vigorous, and was already able to take long walks. The cavity was quite small, and bid fair to be safely obliterated.

The Natural Cure of Disease.—Sam'l G. Armor, M.D., of Brooklyn, N. Y. (*N. Y. Med. Journ.*, Jan. 1873), has a lecture on this subject, being replete in sound sense, and an introductory to the discussion of therapeutics. He emphasizes the following rules of practice:—1st. Never administer a drug of any potency without a definite purpose—that is, without a clear indication—for drugs never occupy neutral ground. 2d. Never use more medicine than is requisite to produce the effect which is intended, and continue it no longer than is absolutely necessary. In closing, he would enforce these truisms:—It is the duty of the physician to restore health by the simplest means in his power. To know the natural cure of disease is more than half of therapeutics.

Case of Occluded Vagina.—Dr. W. T. Lusk, of New York (*N. Y. Med. Journ.*, Jan. 1873), records a case of occluded vagina; labor at full term; forceps; and resuscitation of stillborn child by Schultze's method. The latter plan, unfamiliar to many, is thus described:—The operator seizes the child under the arms, the index-finger of each hand in the armpit, the thumbs over the anterior portion of the trunk, the remaining fingers placed along the back, which is turned toward the operator, while the head is steadied between the palms of the hand. As the operator stands up, the child, so held, is allowed to swing between his outspread knees. The tractions thus made in both directions upon the ribs, by the pectoral muscles above, and the abdominal muscles below, produce the widest reparation of the ribs, while the weight of the liver causes descent of the diaphragm, and thus inspiration is produced. Next, with extended arms the operator swings the child upward until the breech and legs fall forward toward the abdomen. When the body is thus doubled up, the ribs close together, the diaphragm is pushed forward, and forcible expiration takes place, driving out through the month and nostrils great quantities of mucus and fluids — when respiratory movements have taken place previous to birth—from the air passages. Still keeping the arms extended, the child should be allowed, after a few moments, to swing back between the legs. In this way expiration and inspiration are to be maintained, until spontaneous respiration occurs. As the temperature is apt to fall during the swinging movements, warm water should be kept handy, in which to occasionally plunge the child. The child thus resuscitated lived two days, crying most of the time.

Chloroform Poisoning.—Two cases of chloroform poisoning are related by Samuel C. Busey, M.D., Washington, D. C., in the October No. of the *American Journal of Medical Sciences*. In the case of a child, aged 4 years, and the case of an unmarried lady, aged 30, who swallowed large quantities of the anæsthetic, both recovered, following the usual remedies, with application of Chapman's ice-bag to the spine. So far as he is aware, there has been but one death reported from chloroform narcotism, the details of which are found on page 108, vol. 2d, Stille's *Therapeutics and Mat ria Medica*.

Locomotor Ataxia.—D. E. Dickerson, M.D. (*Kansas City Med. Journ.*, Dec., 1872), relates two cases of this affection which were successfully treated with nitrate of silver.

ARTICLES IN OUR EXCHANGES.

SURGERY.

Popliteal aneurism cured by ligature of femoral artery, after failure of compression. Walshe, D. *Med. Press and Cir.*, Jan. 1.

Penetrating wound of abdomen; extrusion of a portion of great omentum; recovery. MacDowell. *Ibid.*

Traumatic pericarditis. Farquharson. *Ibid.*

Fracture of pelvis. Davy, R. *Ibid.*

Cystic tumor of forearm, resulting from a blow. Bell, R. *Ibid.*

Dislocation of the patella on its edge. Bellamy, E. *Br. Med. Jour.*, Jan. 4.

Diseases of the antrum. Vans Best, A. *The Lancet*, Jan. 4.

Compound comminuted depressed fracture of the skull, without symptoms; operation; recovery. Pemberton, O. *Ibid.*

Tumor in the thigh, resembling aneurism; treatment by antiseptic ligature of the femoral artery; death sixteen weeks afterwards from gangrene. Jessop. *Ibid.*

Two cases of extroversion of the bladder. Wood, J. *Ibid.*

Aneurism of the transverse part of the aorta. Johnson, G. *Ibid.*

Encysted hydrocele. Moxon. *Ibid.*

A method of plugging the posterior nares. Taaffe, R. P. B. *Ibid.*

Case in which Allarton's median operation was successfully performed for the removal of an entire gum-elastic catheter from the bladder. Stokes, W. *Irish Hosp. Gaz.*, Jan. 1.

Extensive compound and comminuted fracture of the skull. Kidd, A. *Ibid.*

Cases of stricture of the urethra (illustrated). McDonnell. *Ibid.*

Fracture of the base of the skull. Bennett. *Ibid.*

Dilatation of the kidneys, etc., consequent on stricture. McSWINEY. *Ibid.*

Fibro-sarcomatous tumor of the face. STOKES, W. *Ibid.*

Entero-vesical fistula; muscular fibre as an urinary deposit (illustrated). RICHARDSON, W. *Dublin Jour. of Med. Sci.*

Direct scrotal hernia, with multiple sacs; both testes at the upper and anterior part of the hernia; suspensory bands in one of the sacs (illustrated). RICHARDSON, W. *Ibid.*

Colles's operation for the relief of stricture at the orifice of the urethra (illustrated). RICHARDSON, W. *Ibid.*

Intimate mixture of cancer with enchondroma (illustrated). RICHARDSON, W. *Ibid.*

Self-amputation of genital organs. BARTON. *Ibid.*

Hematocele of very long duration; suppuration at the orifice of the sac from injury; castration. BARTON. *Ibid.*

Lithotrity for vesical calculi. PORTER. *Ibid.*

Two cases of intra-capsular fracture of the neck of femur (illustrated). SMITH, R. W. *Ibid.*

Renal tumor (illustrated). LITTLE, T. E. *Ibid.*

New method for the surgical treatment of ozena. *Bulletin de la Suisse Romande*, Nov.

Sub-ungneal exostosis of the great toe. REDARD, P. *La France Med.*, Jan. 4.

Pyæmia. RANVIER, VULPIAN, HAYEM. *Le Mouvement Med.*, Jan. 4.

Septicæmia. LIONVILLE, LABORDE, VULPIAN. *Ibid.*

Leeeh in the pharynx. DANLOS. *Ibid.*

Contractions of the lower extremity of the rectum, and their cure by incision (*rectotomie linéaire*). VERNEUIL. *Gaz. Med. de Paris*, Jan. 4.

Urethro-prostatic calculus; "button-hole" operation; recovery (illustrated). GROSS, G. *Gaz. Med. de Strash.*, Jan.

Rare tumor of lower jaw successfully removed without division of the bone (illustrated). ANNANDALE, T. *Edinb. Med. Jour.*, Jan.

Hypospadias with cleft scrotum, believed to be a female till fourteen years of age. GRAHAM, T. *Ibid.*

SYPHILIS AND DERMATOLOGY.

Hydroa of probable syphilitic origin. HUTCHINSON. *Br. Med. Jour.*, Jan. 4.

Eczema rubrum—importance of its diagnosis. HARDY. *Jour. de Med. et de Chir. Prat.*, Jan.

Perforating syphilitic ulcers, treated by occlusion by means of a sparadrap containing mercury and conium. SOLARI. *Ibid.*

Note on herpes of the face, and in particular the ophthalmic variety. *Ibid.*

Syphilis in females. FOURNIER, A. *Gaz. Hebdom.*, Jan. 3.

Elephantiasis of the leg (illustrated). MUNRO, W. *Edinb. Med. Jour.*, Jan.

PRACTICAL MEDICINE AND PATHOLOGY.

Pathology of chronic Bright's disease with contracted kidney, with especial reference to the theory of "arterio-capillary fibrosis." JOHNSON, G. *The Doctor*, Jan.

Bright's disease. GULL, W. *Ibid.*

On the employment, in Denmark, of aspiration of medicine, especially with reference to pleuritis with effusion. ROSMUSSEN, VALD. *Irish Hosp. Gaz.*, Jan. 1.

Strumous affection of the spleen and spinal cord. STOKES. *Ibid.*

Hypertrophy of right ventricle, and atheroma of pulmonary artery. YEO. *Ibid.*

Abdominal dropsy. LYONS. *Ibid.*

Two cases of circumscribed pulmonary gangrene from hemorrhagic infarction, the result of submersion; frequent hemoptyses; recovery. FOOT, A. W. *Dublin Jour. of Med. Sci.*, Jan.

Empyema of left side opening spontaneously in left lumbar region; lumbo-pleural fistula. FOOT, A. W. *Ibid.*

Empyema of left side, passing behind the internal arched ligament into the left psoas muscle, and thence into vertebral canal; deposition of lymph and pus upon the posterior surface of the theca vertebralis. FOOT, A. W. *Ibid.*

On the late epidemic of small-pox. DARBY, T., and others. *Ibid.*

Cirrhosis of the lungs. EAMES. *Ibid.*

Extreme contraction of the tricuspid and mitral orifices, unattended by precystolic murmur. CRYAN. *Ibid.*

Cardiac dropsy dependent on extreme and rapid dilatation of the heart; hydropericardium. SMITH, W. G. *Ibid.*

Migraine. ALLIBERT, S. C. and ANSTIE. *The Prac.*, Jan.

New mode of preserving sphygmographic tracings of the pulse. ANSTIE, T. B. *Ibid.*

On a hitherto-unmentioned variety of pyelo-nephritis or hemato-fibrinous pyelo-nephritis (illustrated). OLLIVIER. *Archiv. de Phys. Norm. et Path.*, Jan.

On relapsing typhoid. POTAIN. *Jour. de Med. et de Chir.*, Jan.

Bronchial hemorrhages as viewed in their relation to pulmonary phthisis. TISSIER. *Lyon Med.*, Jan. 1.

Pernicious paroxysms in the course of typhoid fever. LUBANSKI. *Ibid.*

Purulent pleurisy opening externally spontaneously; treated with retained canula and injections; recovery. RIAUX. *Le Bordeaux Med.*, Jan. 5.

Encysted dropsy of the pleura, simulating in its course and symptoms a pulmonary cavity. FRANCK, F. *Ibid.*

The mode by which the feet of Chinese women are deformed. BOUROTE. *Ibid.*

Bacteria and putrefaction. LÉPINE. *Gaz. Med. de Paris.*, Jan. 4.

The histological phenomena of inflammation; essay on a new theory, based upon that of molecular granulation. GRASSET, G. *Ibid.*

Metastatic abscesses. HAYEM, RANVIER. *Gaz. Heb.*, Jan. 3.

Medicine among the Chinese (conclusion). *Ibid.*

Consumption in the highlands and islands of the West of Scotland. SMITH, R. *Edinburgh Med. Jour.*, Jan.

Dilatation of the bile ducts, followed by abscess of the liver. STEWART, T. G. *Ibid.*

DISEASES OF THE NERVOUS SYSTEM.

Relief of pain by constant galvanic current. GALE, H. S. *Med. Press and Cir.*, Jan. 1.

Injury to the spine. ALLEBUT, C. *Br. Med. Jour.*, Jan. 4.

Acute ascending paralysis. *Ibid.*

Paralysis of the seventh nerve. GULL, W. *The Doctor*, Jan.

Tumor of the brain. GULL, W. *Ibid.*

Glioma of the fifth nerve. LITTLE, T. E. *Dub. Jour. of Med. Sci.*, Jan.

Lesions of the walls of the ventricles and adjacent parts in general paralysis. MAGNAN and MIERZEJEWSKY. *Archive de Phys. Norm. et Path.*, Jan.

Primitive sclerosis of the median fibre of the posterior columns. PIERRET. *Ibid.*

Case of spinal paralysis in an adult, followed by autopsy. GOMBAULT. *Ibid.*

An alteration in the cord consecutive to variola. WESTPHAL. *Ibid.*

Anomalies of locomotor ataxy (continued). CHARCOT. *Le Mouvement Med.*, Jan. 4.

PRACTICAL MEDICINE AND PATHOLOGY.

Valvular disease of heart. MARTIN, J. W. *Med. Press and Cir.*, Jan. 1.

On sick-headache. LATHAM, P. W. *Br. Med. Jour.*, Jan. 4.

Extensively disseminated cancer. SIEVEKING. *Ibid.*

Old blood-clot adherent to wall of left ventricle and septum of heart, producing thickening of the endocar-

dium and degeneration of the muscular tissue (illustrated). WHIPHAM, T. *The Lancet*, Jan. 4.

The sarcina ventriculi (of Goodsir). MORE, J. *Ibid.*

Empyema of right side; paracentesis; relief. HARRIS. *Ibid.*

Suppurating hydatid cyst of liver; puncture; recovery. WHITMORE, W. B. *Ibid.*

Pigmentation of tongue, not associated with Addison's disease. GREENHOW. *Ibid.*

Heart-clot. CRISP. *Ibid.*

OPHTHALMOLOGY AND OTOLOGY.

Snellen's method of treating entropion (illustrated). SMITH, P. *Br. Med. Jour.*, Jan. 4.

A peculiar form of iritis which occurs in the children of gouty parents. HUTCHINSON, J. *The Lancet*, Jan. 4.

Cases of sympathetic ophthalmia. WILSON. *Irish Hosp. Gaz.*, Jan. 1.

On the diagnosis of periostitis in the orbit. WATSON, W S. *The Practitioner*, Jan.

New method of establishing the diagnosis of intra-ocular affections without the aid of an instrument. GRANDCLÉMENT. *Lyon Méd.*, Jan.

Foreign body in the ear. MIOT, C. *Le Mouvement Méd.*, Jan. 4.

Sarcoma of the choroid. RICHELOT, NEPVEAU. *Ibid.*

Ruptnre of the choroid. ROBERTSON, A. *Edinburgh Med. Jour.*, Jan.

THERAPEUTICS AND CHEMISTRY.

The morbid effects of alcohol. DICKINSON, W. H. *Br. Med. Jour.*, Jan. 4.

Fifty cases of ether administration in the General Infirmary at Leeds. MCGILL, A. F. *Ibid.*

Death from anæsthetics. CLOVER, J. T. *Ibid.*

Poisoning by carbolic acid. WAY. *The Lancet*, Jan. 4.

Spectrum analysis as applied to the detection of poisons, adulterations, and blood (illustrated). REYNOLDS, J. E. *Ibid.*

Action of hyocyamia. OULMONT. *Bull. de Thérap.* Dec. 15; and *The Practitioner*, Jan.

Transfusion of milk in cholera. HODDER, E. M. *The Practitioner*, Jan.

The influence of the continuous galvanic current over voluntary muscular action. POORE, G. V. *Ibid.*

The action of drugs. SHARP, W. *The Monthly Homœo Rev.*, Jan.

Belladonna poisoning by means of a belladonna plaster. SHULDHAM. *Ibid.*

Nitrite of amyl in suffocative breast-pang. BLAKE, E. T. *Ibid.*

Poisoning by petroleum; treatment by large doses of coffee and turpentine frictions; recovery. BUFFIERE. *Jour. de Méd. et de Chir.*, Jan.

Substitution of tubes of pure rubber for those of vulcanized rubber in making injections of tincture of iodine. SIREDEY. *Bull. de Thérap.*

Method for recognition of the diuretic properties of a remedy, and distinguishing those of green coffee and tea. *Ibid.*

The diagnosis of poisoning by phosphorus, by means of a sign furnished by the urine. LAPEYRERE, J. *La France Méd.*, Jan. 4.

The chemical galvanocaustic. TRIPIER, L. *Le Mouvement Méd.*, Jan. 4.

The elements of medical physics. DALLY. *Gaz. Méd. de Paris*, Jan. 4.

Therapeutical effects of silicate of soda. RABUTEAU and PAPILLON. *Ibid.*

Essence of turpentine as an antidote to phosphorus. *Gaz. Hebd.*, Jan. 3.

Experimental researches on the treatment of asphyxia. LE BON, G. *Gaz Méd. de Paris*, Jan. 4.

The use of tannin in purulent pleurisy after artificial or spontaneous evacuation of the pus. *Jour. de Méd. et Chir.*, Jan.

HYGIENE.

Reports on sanitary engineering in houses, hospitals, and public institutions (illustrated). EASSIE, W. *Br. Med. Jour.*, Jan. 4.

Tangier as a winter resort for invalids. LEARED, A. *The Lancet*, Jan. 4.

Medico-topographical report of Futtegurh, N. W. P., India. CURRAN, W. *Edinb. Med. Jour.*, Jan.

ANATOMY AND PHYSIOLOGY.

Enumeration of blood globules. MALASSEZ. *Le Mouvement Méd.*, Jan. 4.

Abnormal termination of the rectum. HANDYSIDE. *Edinb. Med. Jour.*, Jan.

A monstrosity (syren). MCLAREN. *Ibid.*

A proof of the free inter-communication near the chorionic surface of the placental cells, or maternal blood-spaces in the same, and in different cotyledons. *Ibid.*

Some researches on infant digestion. SONSINO, P. *The Practitioner*, Jan.

Experimental researches on the mode of growth of bones. OLLIER. *Archiv. de Phys. Norm. et Path.*, Jan.

Conclusions of an article on the circulation in the medulla. DURET. *Ibid.*

Influence of the reflex activity of the vascular nervous centres upon the dilatation of peripheral arteries, and upon the secretion by the sub-maxillary glands. OSSIANNIKOW and TSCHIRIEW. *Ibid.*

The anti-fermentiscible properties of silicate of soda. PICOT. *Gaz. Méd. de Paris*, Jan. 4.

A second observation upon several recent communications by M. PASTEUR; especially upon the theory of alcoholic fermentation. BECHAMP, A. *Ibid.*

The *rôle* of microphytes as ferments physiological and pathological conditions, and after death. BECHAMP and ESTOR. *Ibid.*

Lesons on urine. BOUCHARD. *Gaz. Heb.*, Jan. 3.

The physiology of the circulation in plants, in the lower animals, and in man (illustrated). PETTIGREW, J. B. *Edinb. Med. Jour.*, Jan.

Apparatus for maintaining artificial respiration in physiological experiments (illustrated). MCKENDRICK, J. G. *Ibid.*

Experiments to demonstrate functions of different portions of the brain of pigeons. MCKENDRICK, J. G. *Ibid.*

OBSTETRICS AND DISEASES OF WOMEN AND CHILDREN.

Intra-uterine medication in the treatment of chronic uterine catarrh. PLAYFAIR, W. S. *The Lancet*, Jan. 4.

Case of cysts of ovaries. MOXON. *Ibid.*

Guaiac in ovarian affections. CLELAND. *Irish Hosp. Gaz.*, Jan. 1.

On endo-metritis (illustrated). ATHILL, L. *Dublin Jour. of Med. Sci.*, Jan.

Croup and its treatment. DRURY, W. V. *Monthly Homœo. Rev.*, Jan.

Softening of the brain in the newly-born. PARROT. *Archiv. de Phys. Norm. et Path.*, Jan.

Ovarian cyst. *Lyon Méd.*, Jan. 5.

Extra-uterine pregnancy. SOYRE. *Le Mouvement Méd.*, Jan. 4.

Pregnancy of five months' duration; very considerable anteversion; abortion—rupture of the membranes; retention and putrefaction of the fœtus, which came away piecemeal; recovery. RAEIS, E. *Gaz. Méd. de Strasbourg*, Jan.

A case of eclampsia. MONSSEAU, J. O. *L'Union Méd. du Canada*, Jan.

Case of infantile convulsions. YOUNG, J. *Edinb. Med. Jour.*, Jan.

Placenta and cord from a woman believed to have been twelve months pregnant. BELL, C. *Ibid.*

Set of sisters, with families, who had never any milk in their left breasts. YOUNG, J. *Ibid.*

Zymotic diseases as affecting obstetric cases. CAIRNS. *Ibid.*

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, April 1, 1873.

THE WORK OF OUR HEALTH DEPARTMENT.

THE present is a fitting time to take a retrospective glance at the doings of the Health Department which for the past three years has controlled the sanitary interests of the Metropolis. That its administration has been barren of much of the good that was expected of it is now quite apparent. Although the principal causes of inefficiency were due to its faulty organization, to the preponderance of the lay over the medical members, and the political character of its general management, a good deal was left undone by the members of the Board which might have been done to give it that decent measure of usefulness and that practical proof of good intentions which were implied by the very taking of the respective offices and the receiving of the large salaries paid.

The responsible officers of the Board are the Commissioners, six lay and two medical—the Health Officer of the Port being an ex-officio member. Of the lay members we had no reason to expect much, every one believing that they filled such positions by virtue of their qualifications as politicians. In regard to the medical members, however, even allowing for the disadvantage of their being in the minority, we are forced to say that we expected more, but the results of their labors prove a mortifying disappointment. If they have accomplished anything which in a professional sense can be considered of real utility, anything which reflected any special credit upon the profession which they represented, we have yet to hear of it, the reports of the Sanitary Committee to the contrary notwithstanding. This, too, is not owing to the lack of ability of either of the members of the said committee for writing occasional reports and making them finished compositions. In view of the totally negative results of their administration it is certainly unfortunate for their reputation as practical sanitarians that they should have accepted such responsible positions. We say this in all charity to their good intentions, and in appreciation of their desire, with the other members of the commission, of performing the arduous duties of their office with satisfaction to themselves by meeting once a week as a board, and once a week in committee. We are willing to give them the credit also of never complaining of being overworked or of being dissatisfied with the salaries received.

Allowing for all these qualifying circumstances, some have gone so far as to say that the office of Health Commissioner has been a sinecure, and we hope we may not be considered as partial to the verdict of the majority of the profession, and public, on this point, by saying that they have altogether the best side of the argument. Perhaps we can state the case more mildly by saying that these positions were purely political and were given to the different gentlemen more on account of their skilful political manœuvring than for any other qualification.

No matter what may be the cause, we are forced to admit the result that the Commission have been utterly incompetent to control the operations of their department, to the extreme mortification and disgust of such as have an unselfish interest in the sanitary welfare of our city.

What has been lacking in one quarter has, however, been made up in another. The bureaus of sanitary inspection and registration, by the actual hard work performed, have, in reality, been the only means of saving the reputation of the department. Although the labors of these bureaus are freely appropriated by the Commissioners, it is but simple fairness to the gentlemen having charge of them, and their willing and overworked assistants, to state that they in reality have done the only work worthy of mention, or deserving of credit. Dr. Moreau Morris, the former Sanitary Inspector, and Dr. Janes, the present Sanitary Inspector, have been main standbys, as has also Dr. C. P. Russel, the accomplished, scholarly and indefatigable Registrar of Records. These gentlemen have been the true heads, medically speaking, of the Board, and have, by their ability and conscientious regard to duty, given to it all the executive life it ever had.

Those who have done the hardest work of all, but who have received the least credit and the least pay, are the Inspectors and Assistant Inspectors. What is lacking in the capacity for work in the Commissioners is fully compensated by the thankless drudgery of twenty young medical gentlemen whose whole time, in consideration of a mere pittance, is taken up in the inspection of tenement houses, cellars, privy vaults, stables, and in the performance of labor which, if not menial, is certainly degrading. These duties are well enough in their way, and may be indispensable, but

they could have been performed to equal good advantage by a sanitary policeman—a layman in every sense of the term. Owing to the political pressure brought to bear upon the Commissioners, and their desire to create a public sentiment in favor of their continuance in office, the extra work thrown upon these overworked inspecto rshas been, as shown by the number and voluminousness of their reports, to be simply enormous. But this was a political exigency, and must be accepted accordingly.

We contend that the work which has been assigned to the inspectors has not been fitting for medical men to perform. As we have said before, any one of ordinary intelligence can do all the unprofessional duties. How much better would it have been if some duties which, as medical men, they could take a pride in performing, had been assigned to them. There were plenty of opportunities offered for strictly scientific work, and yet there has been almost nothing of the sort done since the organization of the Board.

This has been one of the many instances of the want of foresight in the Commissioners. By assigning strictly scientific work to these inspectors, exceedingly valuable services to the cause of sanitary science could have been made available, and would have been the means of giving a dignity to the working of the Board which it very much needed. Very many questions could be answered by intrusting their solution in detail to a corps of enthusiastic young men, men who would take an interest in the work, an interest which we never can hope to be fostered by the inspections of privy vaults, cesspools and similar duties. Contrary to what might have been expected of a board which above all others should have placed a premium upon medical services, we find that every attempt has been made to degrade the profession in the eyes of the public, and that the medical members of said board have had neither the influence nor the inclination to counteract the tendency. The inspectors have been kept very hard at work and have received very poor pay, while the Commissioners have accomplished little or nothing, and have received very large salaries; but, from a political stand-point, what is fairer than that?

ARTICLES IN OUR EXCHANGES.

We have created in our present number a new department which we have reason to hope will be of service to our readers. It is impossible to present, in a certain amount of space, abstracts of all the papers published in our exchanges. We shall endeavor in our department of Progress of Medical Science to give such epitomes of papers as shall be of real utility to the general practitioner, at the same time giving to those gentlemen who wish for information on special objects the opportunity of seeking for the same in the journals in which the papers concerning them are orginally published.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, Dec. 18, 1872.

Dr. A. L. Loomis, President, in the Chair.

Dr. Post presented a melanotic tumor which he had removed from the cheek of a woman aged sixty. A similar growth had been removed from the same patient a year before. The disease had not affected her general health, neither were there any symptoms of cancerous cachexia present.

Dr. Stimson exhibited a malignant tumor of the kidney removed from an infant.

MYOCARDITIS.

Dr. Sands presented a specimen of myocarditis, with the following account of the case:—

This specimen was removed on Sunday last from the body of a gentleman, a resident of this city, who died very suddenly on Saturday afternoon. I was not his physician at the time of his death, although I had seen him some years previously on account of a surgical difficulty, and knowing him well, was invited to be present at the autopsy. The account which I am able to give of the patient has been obtained from his physicians, Drs. Purdy and Otis.

The patient was fifty-six years of age at the time of his death. No history of previous disease is obtained, except that many years ago—more than twenty—he suffered from a severe attack of acute rheumatism. This disease did not recur, and he was considered to enjoy robust health up to within six weeks of the time of his death. It might also be stated as interesting, in connection with the fact that he died of heart disease, that he was able to go up several flights of stairs with considerable ease, and used to say that he was "long-winded." About six weeks before he died he was exposed to cold and wet, and subjected to some mental excitement and subsequent depression, occasioned by the death of a friend. The disease which followed seemed to be a bronchitis, which did not for the time being make him ill enough to be confined to the house. Three weeks after exposure and about three weeks previously to his death, he was taken with a chill and sent for Dr. Purdy, who attended him for about two weeks for what he supposed to be an attack of pneumonia, Dr. Otis attending in consultation. The symptoms of which he complained were not very distinct as pointing to pneumonia. He had pain, which was referred to the precordial region and extended thence to the region of the left shoulder. This was the only symptom which led to the suspicion that the heart might be the seat of the disease. Careful examinations were made by both Dr. Purdy and Dr. Otis without discovering any physical signs of cardiac trouble. I am told that there was no cough. He had some fever, the pulse was 120, the temperature 102°, and physical examination revealed what were thought to be indications of pneumonia, affecting chiefly the right lung at its base, and involving the left side. Although none of the pathognomonic signs of pneumonia were present, the principal sign was observed on the left side, and consisted of crepitation and dulness, which is said to have extended over a large portion of the back of that lung. He was never very ill, and in short, after being sick in bed for ten days, he recovered, and Dr. Purdy ceased his attendance. I think about ten days before the patient died, Dr. Purdy

made a last friendly visit. Subsequent to this he had not left his room except to drive out once or twice. On Saturday, about half-past twelve P.M., he was seen in his studio, apparently as well as usual, by a servant who went to get him his lunch; and bringing it in half an hour after she had seen him, she found him reclining on the lounge, with his head thrown back, excessively pale, and having a lifeless expression. She not supposing him to be dead, but very ill, ran for a physician, and Dr. Purdy, who was called, says that he reached the house of his patient five minutes after the messenger. When he arrived the patient was dead, and it was not certain that he had not been dead for some time.

A post-mortem examination was permitted, and it was suspected that he had died of apoplexy. I was invited to be present, and remarked that, though he might have died of apoplexy, it was exceedingly infrequent that apoplexy produced such sudden death; accordingly I was not surprised to find an entire absence of any considerable disease of the brain.

The brain was first examined, and there was no disease in the interior of the cranial cavity, excepting a slight atheromatous patch at the bifurcation of the vertebral into the two posterior cerebral arteries.

On opening the thorax and abdomen, no organs excepting the heart and lungs exhibited any signs of disease. The pleura of the right lung near the base was adherent to the costal pleura, and also, I think, to the diaphragm. There were no marked indications of previous pneumonia; perhaps none at all were found in either right or left lung. This is perhaps not strange, insomuch as so long a time elapsed since the acute disease showed itself.

On opening the pericardium, which was found to be a little difficult on account of old adhesions to the heart, it was at once seen that both the pericardium and heart were the seats of disease. The adhesions were chiefly on the anterior and left surfaces of the organ. These adhesions were evidently the result of old disease. A portion of the front of the heart was not affected by adhesions; this portion was the front of the left ventricle pretty close to the posterior thickened border of the heart. What attracted attention at the time was the presence of a very considerable ecchymosis of recent date beneath the pericardium, covering the front of the left ventricle of the heart. The heart was examined *in situ* and the cavities opened, in order to discover if there existed the presence of a thrombus in any of the large vessels springing from its base, but none was found. The heart cavities were moderately distended. When the incision was made to the left of the ventricular septum, to open the left ventricle, Dr. Curtis came upon what he thought to be an abscess or cavity in the heart-walls. Subsequent examination proved this impression to be erroneous. The disease proved to be one of myocarditis. The inflammation of the muscular tissue of the heart was confined to the left ventricle and to the septum between the two ventricles. The heart-wall was thickened to some extent, not, however, by hypertrophy of the proper tissue, but by adventitious deposit, and this is seen to be present, first, on the exterior of the heart where the blood is noticed, and secondly, on the interior of the heart where there is a very thick deposit of laminated fibrine. Dr. Delafield, who examined the specimen after its removal from the body, expresses the opinion that the fibrine on the internal surface of the heart was not effused from the endocardium. On subsequent examination we thought differently. I seized a tissue, evidently distinct, which I peeled off from the effusion underneath. In this patch (pointing to a particular portion of the specimen) the exudation measures in one direction, corresponding with the long diameter of the ventricle, at least three inches, and in the opposite or transverse direction not quite two inches. The texture of the heart intervening between the external and internal clots is evidently very much altered; it is of an ashy color, exceedingly porous, tears readily, and in the direction of the layers of the ventricular walls. There is a considerable amount of atheromatous deposit upon the mitral valves; the coats of the artery and sinuses of Valsalva are studded with many spots, most of them atheromatous. It does not seem that the valves were insufficient to perform their functions. It was also noticed in the examination, and was considered by Dr. Delafield as an element in the causation of the disease, that both coronary arteries were degenerated and more or less obstructed. The right coronary artery is calcified very close to its origin—its walls are so altered that they give quite a ring when struck with the forceps. It contained no thrombus. The left coronary artery was more diseased than the right. It has been examined in its descending and principal branch—the transverse has not been cut into, but it is found to be pervious. The descending branch is very much diseased for an inch and a half of its length. Here (pointing to a particular part of the vessel) the atheromatous deposit is seen in great abundance. Here is a clot, evidently not of recent date—a thrombus—three-quarters of an inch in length, extending from a point where the main artery divides in two principal branches, and almost completely occludes the artery at that point.

Cases of this disease are sufficiently rare to be of interest; and I noticed, in reading Aitken's Practice with Dr. Purdy, that Aitken makes the remark that myocarditis, apart from acute rheumatism (in which case it is evidently different from what it is here), has no clinical history. In Rindfleisch the disease is spoken of as rare, the clinical history of which does not correspond with the gravity of the disease or the importance of the organ affected. It is considered probable that the disease of the heart, myocarditis, depended upon the degeneration of the coronary arteries, the atheromatons especially preventing a due supply of blood to the heart, leading to inflammation, with the successive changes of muscular tissue degeneration, and abrogating its function.

It is remarkable that during life, not only no physical, but no rational signs of the disease showed themselves. The absence of valvular disease would explain the absence of valvular murmur. It is exceedingly remarkable that such an amount of disease in the left ventricle should exist, without having caused any impairment of function of the heart previously to the fatal event itself. Disease of the heart was suspected when the pain was complained of in the præcordial region, but careful auscultatory examination by Dr. Purdy and Dr. Otis failed to detect any valvular murmurs, or any irregularity in the heart's action.

Dr. Peters remarked, that in looking over the Transactions of the Society since '44, there were certainly nine cases of myocarditis reported. None of these had had clinical history, some cases terminating in the so-called aneurism of the heart. In regard to the obstruction of the coronary artery, he remarked: Last winter a gentleman whom I had known for many years, and apparently in perfect health, brought his brother to me with disease of the heart and kidney. An unfavorable prognosis was given and death occurred within two months, when suddenly my well friend complained of an attack very characteristic of angina pectoris, coming on after some exertion. He

had been so well before, that, although I gave him very strict directions about diet and exercise, I did not apprehend anything very sudden in his case. About ten days afterwards he was attacked at night and died very quickly. An autopsy was made by Dr. Janeway, when an entire occlusion of the right coronary artery was noticed.

Dr. Loomis thought, that in Dr. Sands' case the effusion of blood underneath the endocardium was the initial lesion preceding the inflammation of the muscular tissue—an opinion in which Dr. Sands concurred. He also remarked that the recovery from pneumonia was as complete in so short a time as if no pneumonia had existed.

Dr. F. V. White presented a specimen of dilated aorta, tuberculosis, and pulmonary œdema, removed from a male, aged 74, who had died suddenly from the latter disease.

The Society went into Executive Session.

Stated Meeting, January 8, 1873.

Dr. A. L. Loomis, President, in the Chair.

Dr. Delafield reported that the specimen presented by Dr. Hamilton at the previous meeting, and supposed to be malignant disease of bone, proved, on examination, to be osteomyelitis. A detailed account of the microscopical appearances were given.

CANCER INVOLVING RETRO-PERITONEAL GLANDS AND TESTIS.

Dr. Keyes presented an abdominal tumor and testis, the latter removed by operation from a patient of Charity Hospital, aged 23, single, and a laborer by occupation. He was admitted into the institution Oct. 17, 1872. No history of any hereditary predisposition could be obtained, but the patient had the delicate pink complexion indicative of a general unsound condition. He was a left monorchidis, his right testicle never having descended. Four months before he entered the hospital, and after an attack of gonorrhœa, the left testicle began to enlarge and become painful. The patient stated that the enlargement began at the lower end and posteriorly. The increase in size and tenderness continued for a period of thirteen weeks, when the disease remained stationary and he presented himself to the hospital for treatment.

The testicle was examined by Dr. Keyes and several other gentlemen, and found composed of two distinct portions, the lower and inferior portion measuring ten and a half inches around, giving a sense of fluctuation; the upper portion, much smaller, was firm and quite smooth. The cord and seminal vessels were uninvolved. The general condition of the patient was much below par; he had some cough at night; there was a loss of appetite for food, all erotic desires were absent, and he was in a very desponding state of mind. One of the gentlemen thought that the tumor was cystic, and it was tapped accordingly by an exploring needle being attached to a hypodermic syringe. No fluid was, however, extracted. This operation was performed in the latter part of October, before Dr. Keyes came in service. After the puncture the testicle began to enlarge quite rapidly.

When Dr. Keyes took the service, Nov. 1, the patient was clamorous for the operation of castration. By this time the skin covering the tumor had become reddened, but it was not adherent. His appetite was still poor, and his cough became more urgent and distressing. No night sweats were present. The lungs were examined, not very critically, however, but a certain amount of flatness and moist râles were discovered on the right side at the apex, which circumstance gave rise to a general opinion that the disease of the testicle was tuberculous in character. An operation was accordingly refused, but the patient being still importunate, Dr. Van Buren was asked to see the case. He confirmed the diagnosis, and it was decided, after explaining the probable results to the patient, to remove the testicle. No examination was made of the abdomen. The question of cancer was discussed; but no enlarged glands or any other suspicious evidences of the existence of such a disease being discovered in the inguinal or other glands in the neighborhood, the idea was abandoned.

The operation was performed Dec. 1, 1872. The incision was made in the usual manner from above the external ring down through the scrotum, and the testicle was easily enucleated. The spermatic and deferential arteries were tied, when a ligature was placed around the whole cord. There was very little bleeding from the vessels of the scrotum. The scrotum was sewed up in the usual way.

The patient had a very slight chill, but no considerable disturbance. His appetite began to improve, and everything went well until the 13th day, when he began to complain of great tenderness in the left inguinal region, which soon spread over the abdomen and developed into peritonitis. In the course of twenty-four hours the whole of the abdomen was tender and tympanitic, and he died in forty-eight hours.

The extirpated testicle was found to consist of two portions; the upper hard, the lower soft. The upper and posterior portion was made up, for the most part, of three spots of a yellowish-white appearance and hard, looking like spots of chronic inflammation. There were also little cavities on the upper portion which were filled with cheesy deposit, and some with pure pus. The lower portion consisted of a large number of small cysts with a thickening of intertrabecular tissue.

The autopsy was made by Dr. Maxwell. The lungs were found to be healthy, but there was a mass of new growth overlying the pericardium, and attached by one extremity to the inner free border of the upper lobe of left lung. The peritoneum was extensively inflamed. Behind it and a little to the left of the median line, in the upper portion of the abdominal cavity, and overlying the spine, were found two large-sized tumors, evidently taking their origin in the retro-peritoneal glands. When cut into, the substance resembled brain tissue interspersed with more or less cystic growth. The right testicle was found just outside the abdominal ring and entirely atrophied. No microscopical examination of the specimen had been made.

Dr. Krackowizer did not think that there was any connection behind the abdominal tumors and the disease in the testicle, the latter of which seemed to be purely inflammatory in character.

Dr. Keyes, inasmuch as the disease of the testicle was principally in the secreting portion of the organ, and inasmuch as it presented in such a marked degree the gross appearance of encephaloid disease, was inclined to differ with the foregoing opinion. The tumor had not yet been examined microscopically. Dr. Delafield was inclined to agree with Dr. Keyes as to the nature of the tumor in the testicle.

CURIOUS SARCOMATOUS TUMOR OF CHEST—AN INTERESTING QUESTION OF DIAGNOSIS.

Dr. Jacobi exhibited a specimen of lungs and an nexa taken from the body of a child five years of age

who died in a public institution a short time after having suffered from dyspnœa.

He made the autopsy, when a very beautiful and characteristic exhibition of the autopsical appearances of extensive diphtheritic inflammation of the air-passages was shown. The lung in some portions was collapsed, and in others gave evidences of lobular pneumonia.

A second specimen, presented by Dr. Jacobi, also, consisted of the chest contents removed from a child, aged four years, who, according to the mother's account, had always enjoyed good health until a short time previous to death.

About the 20th of Nov. she noticed a slight swelling of the face and body, accompanied with a slight cough. The condition of the child did not in her opinion warrant medical advice, and it was not until the 26th, when the cough had increased and the dyspnœa became more urgent, that a physician was called in. The medical man saw the child several times during the ensuing week, in the course of which time (30th) the mother had occasion to see the child entirely uncovered, and then, for the first time, she noticed that a large number of the external blood-vessels were considerably swelled, and nearly in the same condition in which Dr. Jacobi saw the child, in consultation, sixteen days afterwards. The mother positively asserted that no such appearances were ever present before this accidental discovery. Dr. Jacobi first saw the child Dec. 14th, late in the evening, and found that the chest and a portion of the back were covered with a large number of blue veins—very thick—most of them large vessels, and the communicant veins very much distended. Parallel with the linea alba, and on either side of it, there were three veins, thicker than the rest, and between them a number of communicant veins. In the inguinal and renal regions, and in every direction over the upper portions of the thigh, the same varicose condition existed. The jugular vein was also large, but not pulsating, and the veins over the shoulder and scapula were likewise involved.

The child had the delicate skin and conformation of the chest peculiar to rachitical subjects. There were râles all over the chest, and dull percussive sound anteriorly and posteriorly over upper part of chest. The heart sounds were heard near the left nipple and over a limited space. A dull percussion sound extended in a diagonal direction from about one inch to the left of the mamma to the manubrium sterni—thus giving a triangular space of dulness similar to what is found in hydrops pericardii. There were rhonchi and râles all over the chest. The diagnosis then made was extensive pneumonia of right lung, especially posteriorly, and also hydrops pericardii. From the mother's positive assurance that the child had been well up to the 20th of November, and from the fact that the child had a slight swelling of the face in the beginning, and the urine being free from albumen, it was further presumed that there had been an attack of myocarditis; that in consequence of which deposits had taken place in the heart, that the right auricle had become obstructed, and also in turn the venæ cavæ, and that in consequence of the latter there was the general varicose condition described.

The temperature was 103½. The child died the day after. The autopsy made quite an unexpected revelation, and not only proved that there had been a mistake in the diagnosis, but that the positive assertions of patients' friends are not always entitled to absolute reliance.

The heart was a little enlarged. The pericardium was distended and filled with two ounces of liquid effusion. The lungs were compressed and found in the posterior portion of the chest, where there were slight adhesions. In the median line, a little more to the right than the left, was found a sarcomatous tumor, embedded into the substance of which were the bronchi and all the large vessels at the base of the heart, the latter organ being pushed aside. The tumor probably originated in the lymph glands of the mediastinum and was of fœtal origin, the positive statement of the mother to the contrary notwithstanding.

The Society then went into executive session.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Dec. 23, 1872.

Dr. Ellsworth Eliot, President, in the chair.

The following gentlemen, recommended by the Comitia Minora, were granted certificates of membership:—

John J. Mason, No. 20 East 25th st., a graduate in medicine at the Bellevue Hospital Medical College in 1869; W. H. Vermilyea, 241 East 21st st., a graduate in medicine at the College of Physicians and Surgeons in 1870; W. H. Katzenbach, 35 East 35th st., a graduate in medicine at the Bellevue Hospital Medical College in 1871; Paul F. Munde, a graduate in medicine at Harvard College, Mass., in 1866, and University of Vienna, Germany, in 1871; J. E. Ferdinand, a graduate in medicine at the University of New York, Medical Department, in 1868; Ezra R. Pulling, a graduate in medicine at the College of Physicians and Surgeons in 1853.

DEATH OF MEMBERS.

The Secretary then read, in behalf of the Committee, the following:—

Whereas, It has pleased an all-wise Providence to remove from the sphere of his usefulness our associate and professional brother, Dr. Galen Hunter, who for many years was a member of the Medical Society of the County of New York:—

Resolved, That we record our testimony to the purity of his character, his usefulness, and the integrity of his whole life;

Resolved, That a copy of these resolutions be preserved in the archives of this Society; and, also, that a copy, signed by the President and Secretary, be sent to the family of the deceased.

Committee, { W. N. Blakeman, S. T. Hubbard.

The resolutions were adopted.

Dr. Stephen Rogers announced the death of Dr. Augustus Woolfarth, a member of the Society; and moved that a committee be appointed by the President to prepare suitable resolutions.

The President appointed Drs. Rogers and Finnell.

REPORTS OF COMMITTEES.

Dr. Goodwillie then read the report of the Meteorological Committee; after which Dr. Russell presented that of the Committee on Diseases.

Following the report, Dr. R. Russell read some interesting statistics which had been collected by Dr. Judson, of the Board of Health, relative to the recent epidemic among horses.

The first cases of the disease occurred on Sept. 30th, 1872, at Toronto; and in other cities in the order indicated:—

Ottawa, Oct. 7; Montreal, Oct. 11; Buffalo, Oct. 15; Detroit, Oct. 18; Boston, Oct. 20; Bangor, Oct. 20; New York, Oct. 21; Albany, Oct. 23; New Haven, Oct. 23; Providence, Oct. 23; Quebec, Oct. 25; Burlington, Oct. 26; Philadelphia, Oct. 26; Baltimore, Oct. 26; Cleveland, Oct. 26; Hartford, Oct. 27; Chicago, Oct. 28; Washington, Oct. 29; Titusville, Oct. 29; Pittsburg, Oct. 29; Norfolk, Oct. 30; Richmond, Nov. 2; Wilmington, Nov. 4; Charleston, Nov. 4; Cincinnati, Nov. 8; Louisville, Nov. 9; Lynchburg, Nov. 9; Wheeling, Nov. 12; Savannah, Nov. 15; Columbus, Nov. 16; Indianapolis, Nov. 17; New Orleans, Nov. 26; Galveston, Nov. 28; Houston, Nov. 30; St. Louis, Nov. 30.

Dr. L. D. Bulkley read the report of the section on Dermatology and Syphilis, of the Committee on Intelligence, following which the President appointed Drs. Rogers and Finnell a committee to draw up suitable resolutions with reference to the death of Dr. Wohlfarth.

The paper of the evening was then read by Dr. Wm. J. Moses, who undertook to explain the occurrence of puerperal convulsions in some cases by the effect of pressure exerted on the ureters at the base of the bladder during the passage of the child's head, stoppage of the discharge of urine, distention of the pelves of the kidneys, interference with the renal function, and consequent retention of urea in the blood. This, he thought, might be the exciting cause at least in a considerable proportion of the cases in which convulsions took place during or immediately following labor. He cited several cases in proof of this theory, and was asked by Dr. Jacobi if all, or a majority of them, could be accounted for on this ground.

Dr. Moses thought they could, and said that in every case he had observed convulsions came on when the head was low down, and ceased when the head was extracted.

Dr. Jacobi asked how he would explain cases where convulsions occurred previous to labor.

Dr. Moses supposed them to be due to hysteria, anæmia, or to other causes about which we know but little.

Dr. Jacobi then made somewhat extended remarks upon the causes which have been assumed to produce eclampsia; touching upon the theories which assign to albuminuria, urea, and carbonate of ammonia, the chief causative influence. He also directed attention to the disposition which exists in many persons to convulsive affections, in which cases a very slight cause may sometimes be sufficient to awaken a convulsion, and of these pressure on the pelvic nerves, rather than on the ureters, might, he thought, be the one to blame.

Dr. Moses thought that much might be gained in a practical way by admitting that the cause he had mentioned might be the one in existence, and treating the woman accordingly.

Dr. Hubbard was very much pleased with the paper, but was not prepared to accept Dr. Moses's ingenious hypothesis as a correct theory. He was himself disposed to attribute eclampsia to an uræmic origin; did not believe that chloroform was a proper remedy, but would resort to the use of the lancet at the outset.

Dr. Moses repeated that he advanced the theory to account for a great many, and not all of the cases, and remarked that to put a lancet into the veins of an anæmic patient would lead to results quite as unfavorable as the convulsion itself.

Dr. Merrill thought that if pressure upon the ureters during labor could be a sufficient cause of eclampsia, it might also produce it during the latter months of pregnancy.

Dr. J. C. Peters remarked that in a large class of these cases we may find chronic bronchitial disease present, and in this class the convulsions may occur as early as the sixth month, and cannot be distinguished from convulsions in males under similar circumstances. Although many cases of eclampsia occur in those whose urine contains albumen, we also see a large number in which the albumen does not appear until after the convulsive attack. The class of so-called nervous cases is by no means small. Dr. Peters had of late placed a good deal of importance upon the condition of the function of the skin as having causative influence. In the treatment of the affection he had always had fear of and prejudice against the use of opium on account of its producing a congestion of the circulation in the brain and kidneys, but was aware that the use of morphine hypodermically had become the standard plan of treatment in Bellevue Hospital.

He deprecated any attempt to explain the condition by any *one* cause, and was disposed to await further research before accepting any one of the causes mentioned as *the* correct one.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 6th, 1873.

Dr. Austin Flint, President, in the Chair.

Dr. W. B. Lewis was made a Non-Resident-Fellow.

THE DEATH OF DR. JAMES L. BROWN.

The late Dr. James L. Brown was to have opened the discussion on abortion with a paper on the "Causes, the Prevention, and the Treatment of Abortions," but his remains were interred on the day of the meeting. The President said that the quotation "in the midst of life we are in death" is often remarked, but seldom was it so truthfully exemplified as in the death of Dr. Brown. An opportunity was given to the members for remarks on his death.

Dr. T. Gaillard Thomas said that the announcement of his death took the members by surprise, as he was ill only three days. He mentioned the following particulars concerning the cause of the illness and death: He returned home Thursday evening, January 30th, after his daily round, not feeling well, but commenced writing his paper for the Academy. That night he had a chill. On Friday morning he had another chill; when Dr. Thomas saw him his temperature was 104¾°, and pulse 130. He belched forth lumps of bile. Dr. B. thought he was going to have typhoid fever. On Sunday his pulse was 118, and temperature 101; pneumonia was developed. On Monday the speaker recognized the fact that all hope of saving him was lost; his pulse was from 140 to 150. The signs of pneumonia were well developed in the posterior portion of right lung. Oxygen gas was administered to keep him alive on Monday night. At a quarter before ten on Tuesday morning he died, aged 42 years.

The speaker remarked that the deceased was one of the noblest and most upright men in our profession. He knew him intimately for seventeen years. More than any one else, Dr. Brown built up the Clinic of Obstetrics and Diseases of Women and Children in the College of Physicians and Surgeons. His mental traits were strong, concise, and intense. He had a hard battle in life, and for this he desired justice for all his friends and enemies. Another strong trait was his

entire devotion to duty, and he never turned aside from its path. For his friends he had strong affection, and his loyalty to them could not be surpassed. Professional success was just dawning upon him at the time of his death. As an ovariotomist he would have proved a prominent man. He had already performed two cases of ovariotomy, and was a thorough diagnostician. Dr. Thomas said he was bankrupt in thanks to the departed member, and this affair made the whole profession as one. He moved that a committee of three be appointed by the chair to draft appropriate resolutions.

Dr. Peaslee stated that he had been intimate with Dr. Brown for ten years. His physical, moral, and intellectual capacities were great. In the whole domain of gynæcology not a single point could be raised with which he was not thoroughly acquainted. He was always willing to give up an opinion if he found that he was wrong. The speaker never saw a fairer man. In regard to diagnosis, he would consider the subject twice before taking an opposite opinion to the deceased. When Dr. Brown applied to him for position as his assistant in the Demilt Dispensary, he believed he remarked that he had been through all the other departments in that institution. The deceased, for two of the summer months, had annually taken charge of the speaker's practice (the department of gynæcology and obstetrics) with credit to himself and satisfaction to his patients. Intellectually and morally, he came up to as high standing as he ever saw. The whole truth was never known by the profession concerning him.

In closing, Dr. P. said that the age of from forty to forty-two was the critical period of the medical man. At that age the physician does not then know what is before him. Those of the age of forty, or thereabouts, should wait and let the future come to them—leaving that to Providence. He hoped that the resolutions would be passed that evening.

Dr. James Anderson stated that his acquaintance, though not intimate, was a pleasant one. He particularly exhorted the young and the old to prepare for death, if they had not already done so. He hoped that the thought "that life is not ended here, but is to go on," would occupy their thoughts by day and night.

Dr. Jerome C. Smith reminded the Academy of his sincere honesty; and in early days, when an attempt was first made to remove the masks from the faces of some physicians in establishing the "Medical Register," Drs. Brown and Bibbins did more to put it on a firm foundation than anybody else. Dr. Brown always remembered the other side when subjects were discussed at the meetings of the Medico-Historical Society. He spoke of the great credit due the late member for his devotion to that work.

Dr. Chamberlain said that he could not record such an intimacy with any other member as with Dr. Brown, and the more he was associated with him the more he found him to be the ripe scholar and high-minded man. In all his positions he had great regard to medical attainments. No man, physically, was marked for a longer life than the deceased. He has gone from us and left a bright and noble example.

The President appointed Drs. Thomas, Chamberlain, and J. C. Smith as a committee to draft resolutions. These were subsequently presented and unanimously carried. They have been already published in our journal.

DISCUSSION OF ABORTION.

The President called upon Dr. Peaslee to give some information concerning the views of Dr. Brown on the subject of abortion.

Dr. Peaslee remarked that he called at the residence of deceased, and found that among other points jotted down in the opening of the paper, he would have shown that fibroid tumors and pelvic peritonitis were causes of abortion. The opinion advanced by Dr. Church, that abortion from habit was a cause, he coincided with. In his recorded cases of habitual abortion he was not able to find out any other cause. To illustrate the fact that fibroid tumors was a cause, he had recorded one in full. Dr. Brown thought that placentitis as a cause had been carried too far.

Dr. Peaslee, in speaking for himself, said he had never seen an inflammation of the placenta. He exhibited an interesting specimen of placenta from a woman six feet high and weighing 170 pounds. Just such women were very liable to miscarry at four or five months of pregnancy.

The patient had originally retroflexion, which was arrested. For several years past she habitually aborted at about the fourth or fifth month. She desired to have a child. Her physician, thinking the cause was placental disease, ordered tinct. ferri chloridi and chlorate of potassa three times a day. Afterwards he saw Dr. Peaslee and thought the child was dead. The pyro-phosphate of iron was then given to the end of the term. The speaker doubted whether this preparation arrested placental disease, but it certainly gave better blood to the mother and child. When the child was a fortnight old the patient died from puerperal convulsions. The wife was changed for the daughter.

Dr. Cabo agreed with the author of the paper and the last speaker in the belief of habitual abortion as a cause. Working on the sewing-machine, and fatty degeneration of the placenta, were denominated as causes. Chlorate of potash had been given to one of his patients, but without avail. One of the best means of relief, he thought, was the use of morphia, when there is a certain amount of rigidity of the os, which is a sign that the ovum will pass away. Certainly he would never use ergot, as it causes rigidity.

Dr. W. C. Roberts, in his remarks, spoke as follows concerning the treatment: When the blood is flowing pretty freely, I should at once introduce the sponge tampon, apply ice, urge rest, and ergot, if you like, as a hæmostatic; or better still, opium to arrest contraction. When the os is open and the neck distended, and muscular efforts and contraction has begun, the abortion cannot probably, as Burns says, be prevented. I do not share the fear that some have that the tampon, by confining the blood within the uterus, increases the tendency to contraction by distending the uterus. I do not believe the coagulation goes up far enough. I should never rupture the membranes, as the chance is better while they remain entire of the whole coming away together; whereas, in the other event, the fœtus, big or little, comes away, the womb contracts, and the placenta remains behind. Perhaps, anyhow, a blighted fœtus, etc., may be left behind to be expelled at a later period, perhaps as a mole or in a hydatid condition. The woman will surely abort if the membranes are ruptured; when the life of the fœtus is destroyed from any cause, it must come away, and the sooner the better, as the woman may then conceive again. It happens sometimes, when hemorrhage and pain cease and the os is closed, that the life of the fœtus may be preserved, and the pregnancy go on. Hemorrhages are not infrequent in the early months, which do not interrupt the progress of pregnancy.

Dr. Chadsey considered plethora of the uterus one of the causes of abortion, and in his experience venesection gave relief.

Dr. Thomas was appointed to read a memoir of Dr. Brown. The Academy adjourned.

Correspondence.

DISLOCATION OF PATELLA UPON ITS AXIS.

[The following letter was sent to Prof. F. H. Hamilton, of this city, who has kindly placed it at our disposal.—Ed.]

Dear Sir:—On the 14th inst., at 7 P.M., I was called into the country, a distance of eight miles, to see Miss Minnie P., a farmer's daughter aged seventeen, short and stout, who had received an injury five hours before from a fall from a chair, while endeavoring to wash the wall near the ceiling. I arrived at 8 P.M. and found the patient lying just where she had fallen, on three chairs held by two frightened women, and crying at the top of her voice. In this condition she had been since the fall, some eight hours previously. Upon examining her leg, which lay partially flexed on a chair, I found the patella dislocated by being rotated on its axis inwards, the inner edge lodged in the inter-condyloid depression of the femur, and the outer one standing perpendicular to the plane of its articulating surface.

At once I endeavored to reduce by grasping the bone and canting it over; but to my surprise such a manœuvre had not the least effect upon it except to cause the girl to scream still louder. And again and again, with flexions and extensions, did I try to reduce the dislocation. By this time what seemed at first sight to be trivial, suddenly assumed grave proportions. And I at once resolved to give chloroform, of which I had the precaution to take a bottle along. She passed readily under its influence, and all fear, pain, and muscular rigidity disappeared. With the limited help at hand, two women and a boy, we carried her across the room, by tugging at her shoulders and legs our best, and as she sank heavily, limp and apparently lifeless, on the bed, I grasped the knee, intending to embrace this favorable time for operating, but to my utter surprise and delight the patella had completely reduced itself! I had never seen a luxation of the knee, and had never to the best of my memory read or heard of a similar case. But on returning home I read your article on "dislocations of the patella upon its axis," and found cause to be satisfied with my success in comparison with the treatment of the three you gave—one by Watson, New York, one by Dr. Joseph P. Gazzam, of Pittsburg, Pa., and the other from Sir A. Cooper's work. Yours, truly, H. Hunt, M.D.

Beloit, Jan., 1873.

SULPHO-VINATE OF SODIUM IN CONSTIPATION.

To the Editor of the Medical Record.

Sir:—About two years ago Dr. A. Rabuteau, of Paris, made some experiments with the sulpho-vinate of sodium, and published in the *Gaz. Hebdom.*, June, 1870, the results of these experiments, which were first made upon animals, and afterwards upon himself and his patients. I was so pleased with the conclusions of the author, that I had some of the drug imported for me by Messrs. Eimer & Amend, of this city, and commenced to use it.

The first invoice was a small one and did not correspond exactly with the description given by Dr. Rabuteau. I wrote to this eminent physiologist, asking him at the same time to send me a sample of his sulpho-vinate; but he answered that he had not any, and that he had abandoned the use of this drug on account of its being difficult to keep, and also of its rather high price. I then ordered through the same firm a new invoice, and this last, made by Merk of Darmstadt, answers perfectly the description by Dr. Rabuteau.

It is a salt resembling very much sulphate of magnesia; it is deliquescent when exposed to the air, very soluble in water and in glycerine; its formula is $Na\ (C^2\ H^5)\ S\ O^4 + 2\ H^2\ O$.

It does not, like other salts, produce constipation after passing into the blood, and is eliminated rapidly. It operates at a dose of three or four drachms for an adult, and children even take it very easily; it is administered in Seltzer water, or better, in water with an addition of syrup of lemon, and thus makes a very pleasant drink. It has not the inconvenience of salts of magnesia upon old people or persons subject to calculi.

It is believed to be the best substitute for citrate of magnesia (which is now so impure), or Seidlitz powders, as these generally produce subsequent constipation; and as to the price, one dose will not cost one half of the citrate.

I have used this preparation for over two years, and have made it my standard prescription in cases of chronic constipation, or whenever I need a mild or saline cathartic.

P. De Marmon, M.D.

Kingsbridge, January, 1873.

IS IT NECESSARY TO LIGATE THE FUNIS?

To the Editor of the Medical Record.

Sir: This question, I am aware, has already been decided in the affirmative by most of the profession, but there are some who still contend that it is useless, and should therefore be abandoned. It is to the latter I would especially address this communication. It does appear to me that this question would be forever determined could it be shown that a serious hemorrhage was liable to result from neglect of this simple procedure, and that it was impossible to anticipate the result in any given case.

A few days since, I was called to a babe 36 hours old, at whose birth a midwife had officiated.

She had applied two ligatures to the umbilical cord, and had divided on the placental side of both. The manner of applying these, viz., by wrapping round and round with fine cotton, and tying the extremities, was such that, just prior to my being called, both ligatures became loose. Upon reaching the child I found one ligature entirely removed, while the other did not constrict the cord in the least, and, as the result, a child literally bathed in its own blood. Upon removing the binding, blood spirted at least three feet. The child was blanched, the extremities were cold, and there was every indication that, unless the hemorrhage be checked, the child would speedily die. A stout cord was immediately applied, and the bleeding ceased. After advising the nurse as to the clothing and nourishment of the child, I left. He has since done well.

What I wish to deduce is this: If hemorrhage be possible in a case where two ligatures had been applied, and where both remained for thirty-six hours, is not the danger greatly increased where no ligature is applied?

JOHN T. KING,
A. A. Surgeon U. S. Army.

POST OF SUMTER, S. C., March, 1873.

MECHANICAL TREATMENT OF CONSTIPATION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: In the *London Lancet* for July 25th, 1872, Dr. C. Hilton Fagge, assistant physician to Guy's Hospital, reports a case of intestinal obstruction, which had lasted for five days, and was then relieved by kneading of the abdomen in conjunction with enemas. Dr. Fagge refers to the dangers which might arise from manipulations of the bowels in cases where inflammation and destruction of tissue is in progress, as, for example, in intussusception, and evidently regards the employment of such means in this instance to have been hazardous. Still he says: "It can hardly be doubted that the life of the patient was saved by the kneading of the belly, carried out by his medical attendant; and so satisfactory an issue in this case may well encourage other surgeons to adopt a similar procedure." It has occurred to me that I might render some service by calling the attention of practitioners to this remedial agency, and indicating in a brief way the method of employing it.

A trained manipulator commences the local treatment of constipation by a friction, more or less vigorous, of the abdomen for several minutes. This is followed by the kneading of the abdominal muscles from their origin to their insertion, and by what are technically known as percussion, clapping, chopping, vibration, etc. These preliminaries are intended to promote the nutrition of the abdominal parietes, which is usually much impaired, to the end that the important assistance of healthful abdominal muscles may be secured in promoting a regular action of the bowels. The abdominal viscera are then subjected to their proper treatment. The knees are drawn up or not, according to the condition of the abdomen, and the half-clenched fists of the manipulator are moved about from five to fifteen minutes exactly as are those of the cook who kneads dough for the oven. Then follow vibrations, which are given by placing the palm of the hand on the umbilicus and imparting a series of shocks to the abdominal contents, and percussion over the liver and spleen by the palm or clenched fist. Lastly, the course of the large intestine is followed out by deep pressure with the fingers, kneading, and friction. While these varied manipulations, and others less important, are useful in making thorough the treatment, and in accomplishing special results in particular cases of dyspepsia and constipation, still the simple application of kneading alone is quite sufficient to reach a great deal of the constipation for which the physician is to prescribe. To perform this little, special training is necessary on the part of the operator. Any intelligent servant or friend of the patient, or even, in some instances, the patient himself, can give his intestines and abdominal organs a thorough and vigorous shaking up for a few minutes every day. It matters not how this is accomplished. The method employed in kneading dough answers admirably, and is often all-sufficient.

A great deal of the constipation which the medical man is called upon to treat in our cities is due solely to want of suitable exercise. It should therefore be treated, not by cathartics, but by muscular exercise, in the way of walking, horseback riding and the like, or else by some artificial substitute, when the former are insufficient or cannot be employed. Nature intends the contents of the abdomen to receive a great deal of shaking, jostling, and compression, and without these the healthful action of the viscera is impaired and nutrition suffers. An active man breaks his leg and is confined to the house by the necessary treatment. At once he begins to be troubled more or less with constipation, headache, loss of appetite and dyspeptic symptoms, which distress him throughout the period of confinement, that would be irksome enough in itself. Or, a lady of fashion, whose muscular exercise is chiefly restricted to the effort of dressing, and who seldom goes out of doors except to ride in her carriage, is constantly annoyed by shortness of breath, dyspepsia, constipation, and hemorrhoids. These, and similar instances, may generally be relieved, and often entirely cured, by a vigorous kneading of the bowels, once or twice a day, from ten to twenty minutes.

After having secured a regular action of the bowels in cases of habitual constipation, resulting from sedentary habits, I recommend the patient to carry on the treatment, by employing every morning certain active and passive movements, which tend to agitate the ventral contents and to maintain a healthful state of the abdominal muscles, and then to apply vigorous friction with a coarse towel or flesh brush to the abdomen, flanks and back, at least; if not, to the extremities as well. I have also found that decided benefit may be obtained in such cases by the assumption of the squatting position by the patient during defæcation. This is undoubtedly the natural posture for this act. In it all the muscles which come into play in impelling the fæces can be exerted to far greater advantage than in the sitting position which civilization has adopted, and especially is this true of those perineal muscles whose office it is to expel the remnant of the fæces at the lower part of the rectum.

A great deal more might be added about the treatment of dyspepsia by general and localized movements, alone or in conjunction with internal medication, electrization, etc. But my object has been to call attention to the mechanical method of treating constipation. Its general introduction into practice would tend to relieve many people from a great deal of distress, save their digestive apparatus from injury by cathartics, and take away some of the petty annoyances of the physician.

WM. R. FISHER, M.D.

100 W. 53RD STREET.

New Instruments.

A NEW SPLINT FOR FRACTURES OF THE FORE-ARM,

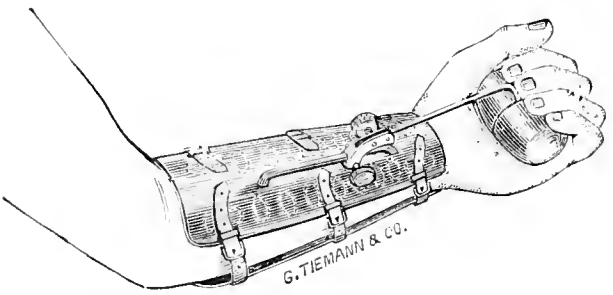
AND ESPECIALLY DESIGNED FOR FRACTURE OF THE RADIUS NEAR THE WRIST-JOINT.

BY HENRY S. HEWIT, M.D.,

VISITING SURGEON TO CHARITY HOSPITAL, CLINICAL PROFESSOR OF SURGERY UNIVERSITY MEDICAL COLLEGE.

THIS splint is intended, in addition to its function as a simple retentive splint, to give support to the hand and

to obviate the danger of partial loss of mobility in the wrist. A few words of explanation in addition to the information conveyed by the accompanying cut may be necessary. The wooden ball grasped by the hand is connected by a rod to a slender bar running longitudinally upon the face of the splint, and capable of being flexed at any desirable length. The rod is attached to the travelling connection by an universal joint giving play to the ball in limited movements of flexion, extension, pronation and supination. The natural tendency is for the patient to make these movements, and to perpetually relax and contract the fingers. The splint upon the inner surface of the arm



is antagonized by a plain flap-splint on the outer surface, extending to the superior border of the wrist-joint. This splint has been used for upwards of two years by myself and others, particularly by Dr. W. T. White, at the Demilt Dispensary, and has given good results. As to my own experience, I have found this method more satisfactory to myself and more comfortable to the patient than any I have hitherto employed, and I beg leave to recommend the instrument to the profession for the purpose of testing its advantages and utility.

129 E. 29TH ST., MARCH 3D, 1873.

ARMY AND NAVY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from March 4, 1873, to March 18, 1873.

CAMPBELL, JNO., Surgeon. Granted leave of absence for 30 days. S. O. 41, Department of the East, March 3, 1873.

BILL, JOSEPH H., Surgeon. To report in person to the Commanding General, Department of the East, for assignment to duty. S. O. 54, A. G. O., March 14, 1873.

MACKIN, CHAS., Assistant Surgeon. Assigned to duty at Yorkville, S. C. S. O. 45, Department of the South, March 4th, 1873.

KIMBALL, J. P., Assistant Surgeon. Relieved from duty in the Department of the Gulf, and to report to the Commanding General, Department of Dakota, for assignment to duty. S. O. 52, C. S. A. G. O.

DELANY, ALFRED, Assistant Surgeon. Leave of absence extended two months. S. O. 51, A. G. O., March 11, 1873.

EWEN, C. Assistant Surgeon. To report to the Commanding Officer, Department of the Gulf, for assignment to duty. S. O. 55, A. G. O., March 12, 1873.

NEW YORK ACADEMY OF MEDICINE.—At the stated meeting, April 3d, Prof. A. L. Loomis will read a paper on "Acute Uræmia."

Changes in the Naval Medical Corps, from February 1st, 1873.

Medical Director W. S. W. RUSCHENBERGER. Waiting orders.

Medical Director J. M. FOLTZ. Naval Hospital, Philadelphia.

Medical Director WM. MAXWELL WOOD. Inspector-General Hospitals and Fleets.

Surgeon HENRY C. NELSON. Recorder Naval Medical Board.

Medical Inspector S. F. COUES. Navy Yard, Portsmouth.

Medical Inspector ALBERT L. GIHON. Special duty, Bureau of Medicine and Surgery.

Medical Inspector EDWARD SHIPPEN. Waiting orders.

Pd. Asst. Surgeon HENRY STEWART. Naval Station, New Orleans.

Surgeon F. E. POTTER. Receiving Ship, Portsmouth, N. H.

Surgeon SOMERSET ROBINSON. League Island Navy Yard.

Pd. Asst. Surgeon H. M. RUNDLETT. Iron Clad Terror.

Surgeon J. H. CLARK. Waiting orders.

Asst. Surgeon S. W. LATTA. Waiting orders.

Surgeon A. A. HOEHLING. Sick leave.

Surgeon THOMAS C. WALTON. To "Juniata."

Asst. Surgeon H. C. ECKSTEIN. Ordered home.

Asst. Surgeon EDWARD EVERS. To "Narragansett."

Surgeon B. F. GIBBS. To "Richmond."

Asst. Surgeon E. C. THATCHER. Resigned.

Medical Inspector ALBERT L. GIHON, as Surgeon of the Fleet on the European Station, June 1st.

Medical Items and News.

NEW YORK ACADEMY OF MEDICINE.—At the stated meeting, April 17th, Prof. William T. Frink will read a paper on "The Etiology and Indications for the Treatment of Irregular Uterine Action during Labor."

BOYLSTON PRIZES.—The Boylston Medical Society of Harvard University have awarded the Boylston Prizes to the following gentlemen: First prize to Thomas Morgan Ratch, for an Essay on "The Emigration of the White Corpuscle in Inflammation." Second prize to Walter Ela, for an Essay on "Fractures of the Elbow-joint."

THE brain of the late Napoleon III. weighed only forty-seven ounces.

PRESERVING TUMORS, ETC.—The "New Method of Preserving Tumors and certain Urinary Deposits," by Jos. G. Richardson, M.D., Lecturer on Morbid Anatomy in the University of Pennsylvania, is reprinted from the Philadelphia *Medical Times*, and is well worth studying. It gives an excellent plan for securing the portability of microscopic specimens.

MERCER COUNTY MEDICAL SOCIETY, N. J.—This Society has elected for the present year the following officers: *President*, C. Shepherd, M.D.; *Vice-President*, John Woolverton, M.D.; *Secretary*, J. B. James, M. D.; *Treasurer*, J. L. Bodine, M.D.

Bowdoin College, Maine.—Robert L. Packard has been appointed Assistant Professor of Applied Chemistry in Bowdoin College.

Hopkins Hospital.—This hospital, to be built in Baltimore, has a fund of two millions of dollars, the bequest of the late Gerard Hopkins.

Holland.—The celebrated English physician, Sir Henry Holland, is 84 years old, being the senior Fellow of the Royal Society.

Mahomet-Ali-Bey.—This Arab surgeon, who has cured the mother of the Khedive of Egypt of a serious malady, has received from his patient a fee of five thousand dollars, and has been raised by the Viceroy to the rank of a Pasha.

College of Physicians and Surgeons, New York.—Since our report of the Commencement of this College, the Secretary of the Faculty has given the following further particulars: Honorable mention was made of the authors of the subjoined theses: George Hart, M.D., Connecticut, "Transfusion of Blood;" Enrique C. Rafael, Mexico, "Physiological Action and Medicinal Uses of the Alkaline Permanganates;" William F. Mittendorf, M.D., New York, "The Examination of Urine;" Charles R. Dake, M.D., New York, "Acute Pericarditis;" Arthur M. Edwards, M.D., New Jersey, "The Application of the Microscope to Gynæcology;" Thomas R. Savage, Rhinecliff, N. Y., "Report of the cases presented at Professor Thomas' Clinique."

The following announcement was made concerning the Stevens' Triennial Prize: The prize for 1873 was given to Dr. Edgar Holden, of Newark, N. J., for a thesis on "The Sphygmograph; its Physiological and Pathological Indications." The subjects for the prize of 1876 are:

1. The History of Epidemic Diseases in the United States from 1860 to 1870; statements as to locality, dates, extent of prevalence, and mortality to be authenticated by appropriate references. The question of treatment not to form a part of the above subject.

2. The use of the Spectroscope in its application to scientific and practical medicine.

The sixty-sixth annual catalogue of this Institution shows that 360 students and physicians attended the session of 1872 and 1873. Of these, 56 had the literary degree of either A.B., A.M. or B.S. During the late session, four special series, each consisting of four lectures, were given by Professor Draper on Diabetes, Dr. Knapp on Plastic Surgery of the Eye, Dr. Peaslee on Disorders of Menstruation, and Dr. Choate on the Medical Jurisprudence of Insanity. Professor Thomas T. Sabine, M.D., is the Secretary of the Faculty.

Alumni Association of Bellevue Hospital Medical College, New York.—Since the annual meeting of this organization, held February 26th, 1873, the following gentlemen have been appointed *Councillors* by the President, Professor W. T. Lusk, M.D.—according to Article 6, of the *new* Constitution, adopted in February, 1872: Leroy M. Yale, M.D., New York; Robert Newman, M.D., New York; Alfred N. Beach, M.D. New York; William O. Sweeney, M.D., Lexington, Ky.; Peter R. Cortelyou, M.D., Brooklyn, N. Y.; John J. Mason, M.D., New York; J. Wallace MacWhinnie, M.D., New York; John W. Pinkham, M.D., Montclair, N. J.; R. M. Wyckoff, M.D., Brooklyn, N. Y.; José de la Cruz de Varona, M.D., New York; William G. Harrison, Jr., M.D., Baltimore, Md.; Charles A. Leale, M.D., New York; Edwin D. Morgan, Jr., M.D., New York; David C. Carr, M.D., New York; William F. Fluhrer, M.D., New York; Washington F. Peck, M.D., Davenport, Iowa; W. Gill Wylie, M.D., New York; William H. Katzenback, M.D., New York; George G. Needham, M.D., New York; and Thomas H. Burchard, M.D. The Councillors and the seven officers constitute the *Council*, to which is referred the business of the Association.

New York Academy of Medicine.—At the Stated Meeting of the Academy, held March 20th, 1873, Dr. Austin Flint, President, in the chair, Professor William Detmold, M.D., spoke of a new method of treating "Facial Paralysis," with illustrations. Professor John C. Dalton followed with an instructive and amusing paper on "Galen and Paracelsus." Drs. Peaslee, J. C. Peters, and others discussed the papers.

Baltimore College of Dental Surgery.—At the Thirty-third Annual Commencement of this Institution, held at Concordia Opera House, February 27th, 1873, the degree of Doctor of Dental Surgery was conferred on 27 graduates. This college was the first to confer this degree in the world, and has graduated the first of the female sex who ever received a diploma in dentistry.

Vienna Professors.—The Vienna correspondent of the Boston *Globe* writes thus concerning some of the medical men of that city: What we regard as professional courtesy seems to be entirely unknown to them, and their code of ethics is very different from ours. The most distinguished among them advertise liberally on their prescription blanks, giving their addresses, office hours, hours for treating the poor, etc. The Vienna doctors are most thoroughly wrapped up in their own ideas, and will not believe that any good thing can come out of—anywhere but Vienna.—Prof. Hyrtl, lecturer on anatomy, he thinks is the best lecturer by far of all the professors there. Next must be reckoned the famous dermatologist, Hebra. He is fat, jolly, shrewd, enthusiastic, always courteous (when he has his own way), speaking five or six languages—and is very popular with the students. Prof. Sigmund is long and slim and sombre, and is quite an uninteresting lecturer, and the American students much prefer his talented and witty assistant, Dr. Grünfeldt. Prof. Braun is very large, with an immense abdomen, sandy whiskers, a merry twinkle in his eye, and a deep mellow voice; the thorough picture of easy good-nature. Prof. Billroth is a large, fine-looking man, with sandy, full whiskers, and a keen blue eye. His researches have made him famous, but few American students attend his kliniks, as surgery is better done in America by far than in Vienna. The most noticeable thing is the amount of surgery that is done without anæsthetics.

Transactions of the Georgia Medical Association.—The twenty-third annual meeting of this Association was held in Columbus, Georgia, on the 10th, 11th, and 12th of April, 1872. The address of welcome was delivered by V. H. Taliaferro, M.D., of Columbus, followed by the annual address by Geo. M. McDowell, M.D., of Barnesville. Drs. C. B. Nottingham of Macon, Robert Battey of Rome, Carlisle Terry of Columbus, K. P. Moore of Knoxville, F. A. Stanford of Columbus, Jno. Stainback Wilson of Atlanta, W. F. Westmoreland of Atlanta, and A. W. Griggs of West Point, contributed interesting papers—which are published in the Transactions—comprising 134 pages. The roll of membership comprises 489 members, of which about 130 were in attendance. The following gentlemen were elected officers for the ensuing year: *President*, G. W. Holmes, M.D., of Rome; *First Vice-President*, Juriah Harris, M.D., of Savannah; *Second Vice-President*, A. W. Griggs, M.D., of West Point; *Corresponding Secretary*, W. C. Musgrove, M.D., of Burke County; *Permanent*

Secretary, S. H. Stout, M.D., of Atlanta; *Assistant Permanent Secretary*, J. T. Johnson, M.D., of Atlanta *Treasurer*, W. O. Daniel, M.D., of Twiggs County; *Curator*, J. T. Johnson, M.D., of Atlanta.

A Novel Way of Prescribing.—Certain British merchant vessels, which do not carry "an experienced surgeon," are supplied with medicine chests, and suitable books of direction. A sailor on board one of these once applied to his captain for relief, his complaint being that "he had something on his stomach." Under these circumstances the skipper consulted his condensed pharmacopœia, and promptly prescribed a wineglassful of No. 15, the drugs being numerically indicated after the symptomatic descriptions of disease. But there had been a run on No. 15, and the bottle was empty. Was Jack to die for lack of medical assistance? Perish the thought! The skipper was a man of ready resource. There was plenty of No. 8, plenty of No. 7. "Seven and eight make fifteen," said the captain; and Jack, to whom the calculation seemed quite natural, took the joint mixture with startling effect; for whatever *was* on his stomach came up with a rapidity that would have astonished the Royal College of Physicians.

The Oldest New York Library.—The New York Society Library, located at No. 67 University Place, containing some 60,000 volumes,—of which, there are some medical works which are not elsewhere to be found,—celebrated November 9, 1872, its one hundredth anniversary at the hall of the Historical Society, corner of Eleventh Street and Second Avenue. Dr. Thomas Ward delivered the centennial address. He said that the first public library of which we have any account was founded at Athens, by Pisistratus, about the year 544 before Christ. The second of any note was founded by Ptolemy Philadelphus, 284 years before Christ, of which 400,000 books and manuscripts were destroyed when Julius Cæsar set fire to Alexandria, in the year 47 B.C. Another library, formed of the ruins of the first until it grew to 700,000 volumes, was destroyed by the Saracens in the year 642, who heated the water of their baths for six months, by burning books instead of wood. The principal libraries of modern times are, first: that of Paris, containing 2,000,000 volumes and 100,000 manuscripts; the British museum, nearly 1,000,000 volumes, which contains more American books than any library in the United States; that of Munich, 800,000; that of the Vatican 300,000, and 40,000 manuscripts; the Boston Public Library contains 192,000; that of Congress, 180,000; the Astor Library, 142,000; the Mercantile Library, 140,000.

Nevada Soda.—A small lake in Churchill County, Nevada, covering an area of seven acres, is a perfect well of carbonate of soda in its almost pure state. Twenty thousand tons a year can be obtained from it. It is pronounced by chemists as remarkably pure, and equal in all respects to the European soda.

Pulse of Various Animals.—Vatel, in his "Veterinary Pathology," gives for our domestic animals the following pulse: Horse, from 32 to 38 pulsations per minute; ox or cow, 25 to 42; ass, 48 to 54; sheep, 70 to 79; dog, 90 to 100; cat, 110 to 120; rabbit, 120; guinea-pig, 140; duck, 135; hen, 140.

Sugar.—M. Robion de la Trehonnais, of Paris, France (*Bost. Jour. Chem.*, November, 1872), in his paper on "Beet-Root Sugar," speaking of the use made of sugar from a very remote period, says that the "Greeks and Romans gathered a kind of honey on the leaves of reeds," as mentioned by Dioscorides in the year 41. The Chinese knew how to extract sugar from the cane in times still more remote. Pliny the younger, who wrote in the year 98, states that medical men, in the times of Nero and Trajan, designated sugar by the name of Indian salt, "which," he says, "while similar to ordinary salt as to form and color, has the flavor of honey." In 1506, sugar-cane was first introduced into the West Indies.

Alcoholics in the United Kingdom.—In 1871 the United Kingdom paid $500,000,000 in gold for intoxicating liquors.

Bioplasm.—The accepted views on "Bioplasm" were well brought out by D. T. Nelson, M.D., Professor of Physiology and Histology, in his introductory address to the regular course of lectures in the Chicago Medical College, Session of 1872-73. The whole has been published in the *Chicago Medical Examiner* of October, 15, 1872.

The London Medical Schools.—The entries at the London Medical Schools since 1868 have reached the totals of 1,231 in 1869; 1,298 in 1870; 1,486 in 1871; and this year they number 1,496. The following are the figures, for this year:—

	New Entries.	All Year's Entries.
Guy's Hospital	83	319
University College	83	273
St. Bartholomew's	79	254
St. Thomas's	51	156
St. George's	47	120
King's College	35	108
London	31	91
Middlesex	22	47
St. Mary's	21	61
Charing Cross	20	48
Westminster	4	19
Total	476	1,496

Forensic Medicine.—By vote of the Faculty of the Medical Department of the University of Buffalo, the Thesis on "Forensic Medicine," by Charles B. Knowlton, is published in the October number of the *Buffalo Medical and Surgical Journal*. He reviews the duties of medical men to courts of law, to medical science, and to their professional brethren.

	TOTAL MORTALITY OF THE U. S.	MORTALITY UNDER FIVE YEARS.
Census 1850	323,272	123,211
" 1860	392,821	168,285
" 1870	492,263	203,213

It is fair to infer from these data that there are causes operating in cities unfavorable to the health and lives of children, that do not exist or manifest themselves so disastrously in the country.

Treatment of Varicose Ulcers.—A. J. Steele, M.D., of St. Louis, Mo. (*Med. Archives*, October, '72), speaks with confidence in the treatment of these ulcers, of that method first proposed by Mr. John Scott, formerly surgeon to St. George's Hospital, after an uniform success in twenty-five cases. The plan, though modified in detail, still retains the author's central idea, which was—equable support to the vessels of the entire foot and leg, and especially of all that part below the ulcer. Nothing accomplishes this end so efficiently as the properly applied adhesive plaster. Bandages alone have not the firmness; they loosen and become relaxed. It is essential that the plaster be evenly applied—no folds or creases, no uncovered angles or spaces—otherwise there will result irritation, pain, excoriation. After the strapping he applies a flannel bandage from five to seven yards in length, and about two inches in breadth. The entire foot and leg to the knee should be included.

Original Communications.

REVIEW OF THE MEDICAL TESTIMONY IN THE TRIAL OF MRS. E. G. WHARTON, FOR THE ALLEGED ATTEMPT TO POISON MR. EUGENE VAN NESS.

By HORATIO C. WOOD, Jr.,

PHILADELPHIA, PA.

The circumstances of the case, as developed at the trial recently held at Annapolis, are as follows:—

Mr. Van Ness was very much engaged through the spring and early summer of 1871, not only in attending to his duties in the banking-house in which he is clerk, but also in settling an elaborate set of private books. He very frequently, if not habitually, rose at 5 o'clock, worked until breakfast time, and immediately afterwards went to the office, where he was busily engaged until about 4 P.M. During this period he usually ate nothing more than a cracker. The interval between 4 and 7 P.M. was devoted to dinner and recreation; after it he worked at the books until 11 P.M., when he went to bed. During the spring and early summer months he suffered from frequent, severe, nervous headaches and from certain strange, occasional sensations in the throat, occurring chiefly when he was excited. These he attributed, on the stand, to a tight shirt-collar, but according to the witnesses called for the defence, at the time of their occurrence he had described them as a feeling of "choking or swelling in his throat." His stomach is so weak that brandy habitually nauseates him, and malt liquors disagree with him very decidedly. During the time in which the occurrences here narrated took place the weather was extremely hot. On the 19th of June, Mr. Van Ness drank claret at Mrs. Wharton's, on an empty stomach. The taste of the claret was natural, but its drinking was followed in a very short time by lightness of the head, giddiness, numbness and stiffness in the back, and general wretchedness, which symptoms, however, passed off spontaneously, without nausea or vomiting. On the 20th of June, when returning from his office, he again stopped at Mrs. Wharton's, and ate, on an empty stomach, raspberries and cream, and drank claret. This time, as he testified, he noticed that the wine had the "taste of peach-leaves."* Shortly afterwards, he was seized with giddiness, numbness and stiffness of the neck, great wretchedness, and finally intense muscular weakness and relaxation. Notwithstanding these symptoms, he walked some squares to the house of his brother-in-law, where some brandy was administered. Immediately after taking this, he vomited "*spasmodically, without nausea*," and was at once so much relieved that in two hours' time he rode to and walked in the park, engaging in free conversation with ladies whom he met there.

On Saturday, the 24th of June, he attempted to rise early, but was forced to return to bed by a very severe headache. About 9 A.M. he had sufficiently recovered to get up, and told his wife that he was unable to eat then, but would stop at Mrs. Wharton's and get some of "her nice black tea and a piece of toast." This he did, and afterwards worked until 4 P.M. At this time he returned to Mrs. Wharton's, having eaten nothing but a slice of toast with the tea since the day before. At Mrs. Wharton's he drank some lager-bier, with what was stated to be compound tincture of gentian in it.*

Shortly after this, on attempting to read, he found that he was partially blind, and the next moment was seized with the same sensations in the head as on the two previous occasions—namely, giddiness and lightness—and on rising from his chair he was unable to stand.

In a minute or two stiffness was felt in the neck, to use his words, "creeping upwards and downwards" until it involved the back and finally the extremities, and he became rigid all over. He now slid off the chair to the floor, and his *jaw became and remained firmly set. After this* he had tetanic spasms which recurred at intervals until 7 P.M. Between the spasms he remained rigid, with marked opisthotonos. The consciousness was lost during the second and all subsequent paroxysms.

The convulsions commenced with a crushing feeling between the shoulders, and the unconsciousness came on either before or simultaneously with the convulsions. During the latter the eyes were closed, the feet crossed, and the toes inverted.

Fanning was not only endured, but was very grateful to the patient. There was marked dimness of vision throughout the attack, also a constant complaint of distress in the stomach and reference of the trouble to that viscus. "Crying spells" alternated with the convulsions. These "crying spells" were variously described by the witnesses—who used such expressions as "he cried like a child," "violent sobbing"—and one lady testified that she never saw a *man* cry so, and that it was these spells which distressed her—not the convulsions. After 7 P.M., although Mr. Van Ness remained "stiff as a board," and had persistent opisthotonos, no convulsion occurred, and about 10 P.M. the rigidity passed off. The treatment used during the convulsions chiefly consisted of the exhibition of 10 and 20-grain doses of chloral, and the inhalation of chloroform. Early in the attack he was vomited with mustard. After a night's sleep, he awoke feeling pretty comfortable until a cup of tea with toast was given him, when nausea and vomiting came on and persisted through the day. Creasote, lime-water and milk, and large doses of prussic acid were administered, and towards night he became quiet. On Tuesday morning he awoke with a desire for food, and two-thirds of a cupful of beef-tea or beef-essence was given him. This agreed with him; but a repetition of the same quantity within an hour caused nausea and a "sensation resembling heart-burn."

In the evening he was wakened and some beef-tea offered him. He refused it on the ground that it had previously made him sick, and as it was disgusting to him, would vomit him. Nevertheless he took it, and, after a time, it did bring on violent vomiting, with burning in the stomach and an acrid or metallic taste and great prostration following the emesis. The metallic taste he stated distinctly was not perceptible in the beef-tea, but *only* in the matters vomited.

Tuesday morning he was better, no more beef-tea was given, and he was not sick, but the muscular rigidity which had disappeared on Sunday *returned in a less degree, and* "*rheumatic pains and stiffness*" *persisted for two weeks.*

* It is proper to state that Miss Nellie Wharton was present at this interview, and on Mr. Van Ness's complaining of the taste of the claret, she drank of it, and said to him that she could not perceive anything wrong about it. It produced in her no symptoms whatever.

* This was put in partly at his own solicitation, and, after Mrs. Wharton's arrest, the bottle was found in the sideboard with the gentian in it.

Upon the above-narrated circumstances the prosecution rested almost entirely its case, at least as far as the medical testimony was concerned. There was no chemical evidence whatever, save only that relating to the tumbler which achieved notoriety in the Ketchum trial. Out of this Mr. Van Ness did not drink, and, further, the prosecution failed to connect it with Mrs. Wharton, beyond the mere fact of its being found in her house in a position where, in the language of one of the witnesses for the prosecution, "hundreds of people" had free access to it. The chemistry of this tumbler has been sufficiently discussed in the *American Journal of Medical Sciences*, and I do not propose to enlarge upon it. It ought to be distinctly known, however, that the open tumbler was carried about in the pocket of a woman inimical to the accused—from house to house, and certainly into one drug-store—that the examining chemist kept no laboratory notes—that he furnished an official statement to the prosecuting attorney, four months after date, "essentially different" from his sworn statement—that everything was trusted to his memory, which is so bad that, although he has been teaching medical chemistry thirty-five years, on the stand he acknowledged that he could not remember the shape of the crystals of tartar-emetic—the very poison in question!

Indeed, the scientific value of Dr. Aiken's testimony may be gauged by the statement which he made, that he dropped some of a solution of the sediment in the tumbler upon a piece of glass, and put the matter left by its evaporation under a microscope magnifying 40,000 diameters, but that the instrument was not powerful enough to enable him to distinguish the shape of the crystals!! Dr. Aiken may have meant 40,000 surfaces, but *he said*, in the quiet of direct testimony, 40,000 diameters.

Drs. Williams and Chew, for the prosecution, took the ground that they could give no positive opinion as to the attacks of the 19th and 20th of June—that the only possible cause of the attack of Saturday, the 24th, was strychnia; and that the attacks of Sunday, Monday, and Monday night were due to tartar-emetic. Dr. Williams was especially positive that he could recognize with certainty tartar-emetic poison, *by the symptoms alone*, and that no other cause could have induced the attacks seen in Mr. Van Ness's case. During their cross-examination both he and Dr. Chew stated that they recognized the case as poisoning at the time of its occurrence; although no precautions were taken or warning given, that the patient having received one dose of the poison, the second should not be administered, and that, the second dose having been given, no opportunity should be afforded for the exhibition of the third. The universally-recognized antidote for tartar-emetic was not given, nor were the matters vomited nor the urine saved for chemical examination. The treatment consisted solely of the administration of creasote, lime-water and milk, large doses of prussic acid, and brandy, the usual remedies for nervous vomiting. Dr. Chew went so far as to testify that the proper treatment of tartar-emetic poisoning was the free exhibition of prussic acid! No comment on this is necessary. Every medical man knows or ought to know that there is a universally-recognized antidote to tartar-emetic, and can judge of the propriety of withholding this antidote, and of giving to a person dying of exhaustion—as men do die in tartar-emetic poisoning—large amounts of the most powerful known depressant!

The reasons these gentlemen gave for their opinion did not possess much closeness of detail, and have passed to a great extent from my memory. Dr. Chew, however, gave as one of the mainstays of his opinion, the "*loss of consciousness during the convulsions!*" and both the gentlemen insisted that strychnia has a very pronounced action on the brain.

As the first expert called by the defence, and the only one who could testify from having heard the previous testimony, and not merely from a hypothetical case, I gave a positive opinion that symptoms *alone* rarely, and in regard to the irritant metallic poisons never, justify the diagnosis of poisoning being made with any degree of certainty; that the attack of the 24th of June could not have been caused by strychnia or other poison, known to myself; that, whilst the symptoms induced by tartar-emetic do not essentially differ from those caused by certain natural diseases or conditions, in so far as there was no purging on the Sunday and Monday of Mr. Van Ness's illness, although the nausea and vomiting lasted many hours, the symptoms were inconsistent with tartar-emetic poisoning, and that natural cause for the vomiting was very apparent. As a conclusion from the above opinion given in detail, I further offered that there was no poison or combination of poisons capable of having induced the sickness of Mr. Van Ness as a whole; that, although the symptoms of the attacks of Sunday and Monday were not absolutely incompatible with the idea of tartar-emetic poisoning yet not only was there no proof that they were due to that drug, but that it was also improbable, because there was no purging, and because obvious natural cause existed for the vomiting. Dr. Claude, of Annapolis, when called to the stand, after I had left Annapolis, strengthened this opinion by what I think was a well-taken point, namely, that the vomiting induced by a single poisonous dose of tartar-emetic would not last eight or ten hours, as did the sickness of Mr. Van Ness on Sunday, especially if the poison were not severe enough in its action to induce purging or violent gastritis.

It is not necessary to bring forward any proof here of the proposition that the symptoms caused by tartar-emetic are not sufficiently characteristic, even in fatal cases, to distinguish the poisoning from the natural disease. All authorities agree as to this, and the point becomes still stronger when the symptoms do not pass beyond nausea and vomiting.

The reasons on which I based my assertion that the convulsive attack could not be due to strychnia are given below in a tabular form, with references to such authorities as I could consult at Annapolis before giving my opinion:—

Mr. Van Ness's Case.	Strychnia Poisoning.
Commenced with blindness and weakness.	Begins with exhilaration and restlessness, the special senses being usually much sharpened.* Dimness of vision may in some cases be manifested later, after the development of other symptoms, but even then is rare.
Muscular symptoms commenced with rigidity of the neck, which gradually "crept over the body," affecting the extremities last.	Muscular symptoms commence in the extremities, or the convulsion, when the dose is large, seizes the whole body simultaneously.†
Jaw rigidly set before a convulsion, and remained so between the paroxysms.	Jaw the last part of the body to be affected; its muscles relax first, and even when during a severe convulsion it is set, it drops as soon as the latter ceases.‡
Persistent opisthotonos, and intense rigidity between the convulsions, and after the convulsions had ceased.	Muscular relaxation (rarely a slight rigidity) between the convulsions, the patient being exhausted

* Taylor on Poisons, p. 682. Wormley, Microchemistry of Poisons, p. 536.

† Wormley, p. 556. Stillé, Therapeutics, vol. ii., p. 148.

‡ Taylor on Poisons, p. 134 and p. 682. Medical Jurisprudence, pp. 540, 541, 536. Tardieu, p. 934.

ceased, the opisthotonos and intense rigidity lasted for hours.	and sweating. If recovery occur the convulsions gradually cease, leaving merely muscular soreness, and sometimes stiffness like that felt after violent exercise.*
Consciousness lost as the second convulsion came on, and lost with every other convulsion, the disturbance of consciousness and motility being simultaneous.	Consciousness always preserved during convulsions, except when the latter become so intense that death is imminent from suffocation, in which case *sometimes* the patient becomes insensible from asphyxia,† which comes on during the later part of a convulsion, and is almost a certain precursor of death.
Desired to be fanned.	The slightest "breath of air" produces a convulsion.‡
Crying spells, in which he "sobbed violently," and "cried like a child," alternated with the convulsions.	Patient may scream with pain, or may express great apprehensions, but such "crying spells" would appear to be impossible.
Eyes closed.	Eyes stretched wide open.§
The spasms in leg must have been partial, as the feet were crossed and toes inverted, which could not happen if all the muscles were involved, because the muscles of eversion being very much the stronger would of necessity overcome the antagonistic muscles, and the feet be everted.	Legs stiffly extended, with feet everted, ‖ as the spasms affect all the muscles of the leg.
After the cessation of the convulsions, and the complete relaxation of the muscles through Sunday and Monday, the rigidity returned on Tuesday or Wednesday and lasted two weeks, as "rheumatic pains and stiffness," without any allegation or apparent possibility of a second dose of strychnia.	No return of the symptoms is possible, without the exhibition of a second dose.

Many of the above characteristic symptoms of strychnia poisoning are not only sustained by authority, but are plainly inherent to the very nature of the matter. Thus, as strychnia does not act on the brain, consciousness cannot possibly be lost save only when the disturbance is sufficient to induce asphyxia, bordering upon fatal arrest of respiration. Again, strychnia does not originate motor disturbance, but only puts the spinal cord in such a condition that the slightest external irritation brings on a convulsion. The well-known experiment of Claude Bernard proves this; he found if the afferent nerve-roots were cut no convulsions followed the injection of strychnia.

Judging, therefore, from the known physiological action of strychnia, it would seem that it cannot cause persistent rigidity and opisthotonos. Hysteria, as is well known, frequently does so, and Taylor in his work on poisons states that hysteria is to be distinguished from strychnia poisoning by the occurrence of persistent rigidity and unconsciousness.

The staring, open eye of strychnia poisoning is an apparently trivial symptom, but in reality it is a local expression of a primary principle or fact, namely, that in strychnia poisoning the fully-formed convulsions are universal, affecting all the voluntary muscles; this principle, the eversion of the feet, is another local expression of this general law. On the other hand, the hysteroidal convulsion is very generally partial, and affects groups of muscles.

It is very evident that the convulsions in the case of Mr. Van Ness were of the latter character. The prosecution attempted to make capital out of the fact that reflex convulsions were excited by touching, in the case of Mr. Van Ness. Now, over-susceptibility of the reflex centres is not at all peculiar to strychnia poisoning; if there be anything peculiar connected with the state of the spinal centres, in the latter condition, it is the *degree* of this over-susceptibility—it is the existence of an over-susceptibility so intense that the slightest breath of air is unendurable, and provokes convulsions. This intensity of morbid activity did not exist in the case of Mr. Van Ness. It was repeatedly testified that he wanted to be fanned all through the attack.

As none of the characteristic symptoms of strychnia poisoning were present in the case of Mr. Van Ness—as almost, if not absolutely, every diagnostic symptom of the hysteroidal convulsion was brought out piece by piece in the evidence—I could not, and still cannot, arrive but at the conclusion that the attack of the 24th June was not strychnia poisoning, but a hysteroidal convulsion, perhaps the result of gastro-intestinal irritation produced by lager-bier, but very possibly an outbreak merely coincidently, and not causally related to the drinking of the malt liquor.

It is a fact insisted on by Sir Ranald Martin, and one which I can confirm by my own experience, that exposure to heat does occasionally induce hysterical outbreaks in men, and the intense heat of that 24th of June may have had something to do with the attack of Mr. Van Ness.

During the latter part of Saturday afternoon, Mr. Van Ness was kept for hours more or less completely under the influence of chloroform, and a number (how many was not stated) of ten and afterwards twenty-grain doses of chloral were given during the same afternoon and evening. When he awoke the next morning and took some food, he had nausea, heart-burn and vomiting, which continued during the day. I suppose there is scarcely a physician who has not seen similar symptoms induced by so feeble a narcotic as a single grain of opium, and yet Drs. Williams and Chew positively testified that nothing but tartar-emetic in the food could account for the symptoms!

Again on Tuesday morning two-thirds of a cupful of beef-tea (essence?) having been relished, the same dose repeated within the hour nauseated him and produced heart-burn. Surely there is nothing strange in this; its parallel is an every-day occurrence.

The same evening Mr. Van Ness was waked up and beef-tea was offered him; he objected strenuously to it on the ground that it had disagreed with and sickened him before; notwithstanding this he finally took it, fell asleep, and in a short time waked up, "with oppression on the chest, intense burning and great nausea;" he vomited freely and was very weak and faint after it. Nothing wrong was perceived in the taste until after the vomiting. The medical experts for the prosecution contended that these symptoms could be due only to tartar-emetic—those for the defence that they were perfectly explainable upon the idea that the whole attack of sickness from the first to the last had as a large element gastric derangement, and that these symptoms were simply due to the beef-tea disagreeing with the stomach. Although Dr. Williams stated that there was frequent purging, according to Mr. Van Ness's testimony there was very little if any action on the bowels, and as at no time was opium or other remedy given to check diarrhœa, it is very evident that none of moment occurred.

The whole case, as viewed by the defence, can be summed up in a few words. A gentleman of nervous temperament, as a result of overwork and intense heat, suffers from symptoms of gastric irritation following the taking of claret and lemonade; the next day a similar but more severe attack occurs as the result of drinking

* Taylor on Poisons, pp. 134, 136, 682. Wormley, pp. 536, 540, 541. Tardieu, Clinique sur l'Empoisonnement, pp. 924, 938, 939. Husemann, Handbuch der Toxicologie, p. 168.

‖ Tardieu, p. 924; also other authorities, which I neglected to note, and at present writing have not at hand.

claret upon raspberries and cream taken when the stomach was empty; after this there is a third attack commencing with precisely similar symptoms, but ending in a hysteroidal convulsion, during which chloral and chloroform are freely administered; the next day intense nausea and vomiting, partly resulting from the drugs used, partly due to gastric disorder; the day after that nausea from overcrowding the stomach with beef-tea, and finally severe vomiting from a further dose of the same actively disagreeing with the stomach.

The assignment of any importance to the assertions of a man, whose stomach was so entirely out of order, as to the taste of the matters vomited, seems to me simply ridiculous.

During the attack of Saturday Mr. Van Ness stated frequently that the attack was of the same nature as those of the 19th and 20th of June, and on the witness stand he asserted that the first symptoms of the three attacks were almost identical. The attacks of the 19th and 20th ended in great weakness and muscular relaxation, that of the 24th in a convulsion. The unity and the diversity of these attacks cannot be accounted for on the supposition of poisoning. On the other hand, it is well known that stomachic irritation will at one time induce profound weakness—at another time convulsions—or it may produce these two states consecutively one after the other, precisely as occurred in the attack of Saturday.

At the trial several side issues were brought into the case—alleged attempts by Mrs. Wharton to poison others in the house. Both of the supposed victims were ladies, and it does not seem necessary here to discuss the matter at length, as the medical experts for the prosecution did not express any opinion about the attacks; the evidence being simply brought in to affect the jury, although no one dared to say that the cases were really poisoning.

I stated my belief that these attacks were merely sympathetic, the result of the emotions and imagination acting on the body. It was very plain they were not due to any known poison, at least in one of the cases, as great prostration, nausea, "things looking dark," etc., followed "the merest sip possible of milk *as bitter as gall*." No bitter poison is known which produces any such symptoms, unless it be given in very large amounts. The other attack came on after warming beef-tea over the fire, and the offending material was also only merely tasted and was *bitter*. When it is further remembered that these witnesses were exceedingly inimical to the accused, I do not think any weight ought to be attached to the matter.

Before closing the present article the writer thinks it but justice to the lady who has suffered so deeply from the accusations which have been made against her, to call attention to the peculiar circumstances surrounding the expert testimony on the part of the prosecution—circumstances which in justice, if not in law, ought to have excluded it from the court-room. As every one knows, Mrs. Wharton, before the present trial, had successfully resisted the charge of poisoning. It is a matter of history that the public sentiment against Mrs. Wharton, which demanded her trial, had its origin, as had the judicial proceedings, in the blundering of Dr. Aiken and his colleagues. The positive official assertion of the former that he had found twenty grains of tartar-emetic in the stomach of General Ketchum, backed by the whole moral and professional force of the University of Maryland, was months before the people uncontradicted; no wonder that public opinion became so set that no subsequent evidence could shake it, especially when supported as it became by local pride and local prejudice.

At the first trial the whole faculty of the University, from the porter at the gate to the most learned Professor, appeared in support of their colleague, Dr. Aiken, until they were all compromised equally with him, and their reputations equally involved with his. What was the real scientific value of their testimony; what amount of justification there was for their extraordinary conduct; what truth in their assertions that General Ketchum was certainly poisoned, the following extract from the new edition of Taylor's *Medical Jurisprudence* portrays. No man can question the authority of Dr. Taylor on such a point; no man can allege that his mind could have been biassed in London in favor of any one tried at Annapolis. The elements for a true, calm judicial judgment were all present, and this is what he says:—"Mrs. E. G. Wharton was charged with the poisoning of her friend General Ketchum. The trial lasted fifty-two days, and an astonishing amount of evidence was brought forward by the prosecution and defence, apparently owing to the high social position of the parties, for there is nothing, medically speaking, in the case itself, which could not have been settled in forty-eight hours. The General died after a short illness, but the *symptoms*, taken as a whole, *bore no resemblance* to those observed in poisoning with antimony, and but *for the alleged discovery* after death of tartar-emetic, no *suspicion of poison* would probably have arisen. . . . . The chemical evidence does not therefore conflict with the pathological, for it failed to show with clearness and distinctness the presence and proportion of poison said to have been found. *The evidence that antimony was really there was not satisfactory*, and that 20 grains were in the stomach was wholly unproven."

The medical experts who appeared against Mrs. Wharton in the Van Ness case had been in the fore front of the previous trial, and had apparently their reputations and consequently their interests involved in the result of the second trial; for if, as they had asserted, Mrs. Wharton was guilty of the murder of General Ketchum, she escaped conviction through their ignorance and carelessness. In the case of Mr. Van Ness, it was the same story. Under such circumstances how could they claim that impartiality upon which, as Chief Justice Shaw has well said, rests all the value of expert testimony?

In conclusion, because my testimony and actions have been grossly misrepresented by certain of the Baltimore newspapers, and because even my motives and personal integrity have been called in question, a few strictly personal remarks seem to be allowable. I desire simply to state that until after the recent trial I had never read any medical or other account of the first trial, and that my agreement with Mr. Thomas, the senior counsel for Mrs. Wharton, was, that my duties should be to aid in bringing out the facts of the case, and to give privately to Mr. Thomas a professional opinion thereon—for this and this only was a fee to be received. It was to be left to Mr. Thomas whether this opinion should also be promulgated from the witness stand, but for going on the stand no fee whatever was to be given or taken. I had therefore no possible interest to serve in this matter, and whatever the profession may judge of my opinion, I do insist that, as far as possible, it was formed without bias.

After my mind was settled and my opinion officially delivered, not to have felt and shown disapproval of what seemed to me the most extraordinary, ignorant, or biassed, and untrue expert testimony given by the medical gentlemen engaged in the prosecution of Mrs. Wharton, not to have felt and expressed any sympathy

with the victim, would, I confess, have lowered me in my own estimation.

THE ELECTRO-THERAPEUTICS OF DISPLACEMENTS OF THE UTERUS.

By EDWARD C. MANN, M.D.,

BROOKLYN.

It has long been and is, at the present day, one of the most difficult problems relating to gynæcology, how to establish a complete cure for displacements of the uterus; and it remains to be seen, whether, in many cases, electricity may not be one of the most efficient means in the hands of the profession for accomplishing the desired end. We take the liberty of referring to the normal anatomy of the supports of the uterus, which demand our especial attention, as being the parts upon which we wish to bring electricity to bear, when that organ is in a state of displacement. The uterus is suspended in the pelvis and prevented from descent by three agencies, viz.: The vaginal walls whose structure is blended with that of the uterus, the longitudinal muscular fibres of the vaginal walls being continuous with the superficial muscular fibres of the uterus. Secondly, by areolar tissue, which surrounds and binds it to the bladder, rectum and pelvic walls; and thirdly, by the ligaments; the utero-sacral and utero-vesical ligaments, which attach the cervix respectively to the sacrum and bladder, completing the means of support against prolapsus in the first and second degree, the broad ligaments not being brought into action until the prolapsus has become complete. Retroversion is prevented by the round ligaments which are continuous with the tissue of the uterus, with which their structure is identical, and which pass from the fundus to the pubes.

The transversalis muscle also sends muscular fibres to these ligaments, which fact is interesting as connected with the application of electricity to the abdominal region. Anteversion is prevented by the bladder, the broad ligaments, and the columns of the vagina. It is evident that in displacements of the uterus, the uterine ligaments must be on a constant stretch, and that although naturally elastic, yet such a prolonged strain must cause them to lose in time their elasticity, and that all means employed for a permanent cure will be worthless, unless we can in some way impart the wanting tonicity to the partially paralyzed muscular fibres, both of the ligaments and vaginal column. In many cases the vaginal walls and sphincter vaginæ have lost all their tonicity, and are in a state of atony and semi-paralyzation, and the uterus descends for the want of its chief support. We find in the state existing after parturition a fruitful cause for prolapsus, and a wide field for electro-therapeutics. The uterus is much heavier than usual, and the vagina and sphincter vaginæ very much relaxed and feeble, and the ligaments are also stretched very much. In cases of prolapsus from the above mentioned predisposing causes, we may hope for complete cure from the use of local and general electrization; and the beneficial action which we can exert upon the uterus and its ligaments, and upon the vagina, cannot be surpassed by any other remedial agent.

We find in these cases a want of muscular contractility in all of the uterine supports.

Now, if we can, by faradization or galvanization, or both combined, produce contractions of the muscular fibres of the ligaments, we shall thus restore their elasticity, and mechanically draw the uterus back to its normal axis; and if we restore the tonicity of the vaginal walls and cause contraction of the longitudinal muscular fibres of the vagina, and these applications are continued for a sufficient length of time, the uterus must be, of necessity, gradually restored to its proper position in the pelvis. The use of pessaries affords but a temporary relief; and it remains for electro-therapeutics to establish a permanent cure for this condition which afflicts so large a number of the female population. We have treated successfully four cases in all of which there was a slight prolapsus owing to the above mentioned causes, and under local faradization (the negative electrode being introduced into the vagina and the positive being applied externally over the uterus and its appendages, also both poles being applied externally), the vaginal walls and sphincter vaginæ recovered their normal tonicity and elasticity, the ligaments were also strengthened, and the uterus was restored to its normal axis, owing to the mechanical effect thus produced by the induced current. In all these cases the prolapsus was slight, but there is every reason for believing that equally good results may be obtained in cases of this kind even if they are far worse than the above mentioned ones. In inversion which is often dependent upon the relaxation and inertia subsequent to delivery, the application of electricity by the intra-uterine electrode may prove a valuable adjuvant after reduction, the effect being to overcome the relaxation and inertia of the uterine walls. In anteversion depending upon laxity of the abdominal walls, that takes away the support of the viscera, and which is often produced by the pernicious habit of wearing very tight clothing, which forces down the viscera upon the fundus, we find the utero-vesical ligaments in a lax state, and if we wish to accomplish a complete cure, we must restore their normal elasticity, and for this there are no means equal to electricity. It is needless to add that the undue pressure exerted by the clothing must be stopped as well after as during treatment, if we expect an ultimate cure.

In anteflexion due to an undeveloped state of the uterine parenchyma, which is a condition frequently met with, the application of electricity would stimulate the growth of the uterine tissue, and impart tonicity to the utero-vesical ligaments, and thus perhaps aid in restoring the uterus to its normal position. In retroversion due to sub-involution and relaxed support, or occurring as a sequence to parturition, we may hope in many cases for the best results from the mechanical effects of the induced current upon the uterus and utero-sacral ligaments. The application of electricity in these cases is intended mainly to aid in keeping the uterus in position after it has been replaced by imparting strength to the uterine walls, which have been weakened very often, as the result of inflammation, pregnancy, or parturition. In retroflexion, which is generally the result of some influence which weakens the uterine walls, the round ligaments are relaxed, and the abdominal walls are generally lax. Subinvolution may also act as a cause of retroflexion. In these cases we find the uterus flabby and large, owing to the retardation of the process of absorption by inflammation, congestion, or atony. The local application of the induced current in such cases will act on the contractile fibre of the uterus, overcoming the atony which exists, and causing contraction, and will also aid in overcoming the ergorgement which often exists. The use of the galvanic current will aid materially in promoting the process of absorption and should be used in connection with the induced current. The applications should be made by introducing into the uterus the negative pole

by means of the intra-uterine electrode, while the positive pole may be applied to the hypogastric or lumbar region, or introduced into the bladder or rectum by means of an insulated vesical or rectal electrode. In this way a very strong current can be borne, with but little discomfort to the patient. The application of the induced current to the abdomen will also be of great service in many cases, by overcoming the laxity of the abdominal walls. Superinvolution or atrophy of the uterus due to interference with the process of involution by inflammation may be often successfully treated by electricity. In such cases the cavity of the uterus is much diminished, and the process of menstruation interfered with or entirely absent. The application of electricity in these cases by means of the intra-uterine electrode will stimulate the growth of the organ, and at the period at which the menses have been accustomed to appear a strong current may be passed through the uterus and ovaries, which will in most cases probably result in the re-establishment of the menstrual function.

The use of general faradization will in a majority of cases probably relieve the nervousness, hysteria, and neuralgia, which so often accompany atrophy of the uterus. One very marked case of this kind occurred in a lady of 25 years of age, Mrs. B. Digital examination revealed the uterus high up in the pelvis very small and very light. The cavity of the uterus measured but 2¼ inches. There was no menstrual discharge; the result being that the patient was excessively nervous and irritable, and was very hysterical.

Applications were made locally to the uterus, the negative pole being introduced into the uterus by means of the intra-uterine electrode, while the positive pole was applied to the hypogastric region. After eight applications the cavity of the uterus as measured by the probe had increased from 2¼ to 2½ inches, and digital examination proved conclusively an increase in size and weight. General faradization resulted in a great improvement in the general health, and was the means of relieving the nervousness and hysteria which had been so troublesome. The amenorrhœa was entirely cured, and when the last examination was made, the cavity of the uterus measured 2⅝ inches, as nearly as could be determined, and the patient reported that her courses had been normal on the preceding menstrual epoch. At the commencement of treatment, when the time for the menses to appear had nearly arrived, a strong current was passed through the uterus and ovaries, with the purpose of exciting them, and with satisfactory results, and this was continued throughout the treatment on each month with the same good results.

As the galvanic current has a greater chemical, catalytic, and electrotonic action than the faradic, and also causes greater molecular changes in the tissues, the effects of it would therefore be more powerful and lasting; and, on the other hand, as the superior mechanical effects of the faradic current are to be desired also, a combination of the two currents, or galvano-faradization, would doubtless be more efficacious in many cases than either alone, in the treatment of displacements. For this purpose it would be necessary to employ two double electrodes. General faradization and central galvanization in many cases cannot fail to be of service in improving nutrition, and relieving many of the nervous symptoms which are coexistent with displacements of the uterus.

In closing, we desire to present a case of prolapsus of long standing, which was successfully treated by faradization. Mrs. H., married. Has had two children, the youngest three years old. Has suffered for seven years from prolapsus, which came on after the birth of the first child. This was partially relieved by treatment by her attending physician, and four years after she again became pregnant, and had a tedious and painful labor, and was finally delivered by the aid of forceps. Shortly after, there was complete procidentia, which was restored by the attending physician. Was first seen by the writer about a year ago, and gave the above history. She was then suffering from prolapsus in the second degree, complicated by amenorrhœa, obstinate constipation, dyspepsia, vomiting, and severe coccyodynia. She complained of great tenderness and pain in the region of the coccyx, and could not bear pressure over it. The pain was of a sharp neuralgic nature, and was increased by rising from a sitting posture and in defecation. This condition was the result of the last parturition. Treatment for the prolapsus was commenced by faradization, the applications being directed to the vagina and uterus, and to the hypogastric and lumbar regions. Vaginal examinations from time to time showed that the uterus was being slowly but surely restored to its normal axis. The laxity of the abdominal walls, which had been very marked, decreased; the menses appeared; and under general faradization and ferruginous tonics, came restored appetite and a cessation of the dyspepsia, vomiting, and nervous irritability which had made the patient's life a burden to her. The constipation was also relieved by the applications to the abdomen. The treatment was continued every other day for six months, at the end of which time the uterus was perfectly restored to its proper position in the pelvis. The coccyodynia was treated locally, the negative electrode being applied to the painful spot, and the positive pole being applied on either side of the coccyx, a strong current being employed. These applications gave almost immediate relief, and this relief was rendered permanent by their application being made as long as the patient remained under treatment. This is the only case of coccyodynia that we have treated, but the marked relief that was afforded would seem to indicate the propriety of the use of electricity in such cases, inasmuch as the only medical cure heretofore has been found either in section of the muscles, or extirpation of the coccyx.

Another case of but a few months' standing of prolapsus in the first degree, due to parturition, was relieved after a few applications of local and general faradization, and the general health of the patient much improved.

CASE OF ACUTE RHEUMATISM, WITH PERICARDITIS,

SUCCESSFULLY TREATED WITH THE COLD BATH.

By H. W. BOONE, M.D.,

A. A. SURG. U. S. A., FT. HALL, IDAHO.

From time to time various medical journals have contained reports of the good effects of the application of cold in rheumatic hyperpyrexia. In the July number of the *Practitioner*, Dr. Charles Kelly, Asst. Physician to King's Coll. Hospital, reports two cases of considerable interest. In his own words: "Both suffered from their first attack of rheumatic fever; both had similar symptoms, and in both the pericardium was inflamed. The man seemed to be going on very well for a time, but then his temperature went up and he died; the woman, who was equally ill, and in whom the temperature was still higher, was cooled

down more than six and a-half degrees in four and a half hours, and made an excellent recovery." In the case of the woman, the simple addition to the treatment of cold applications seems to have turned the scale and saved her life. Prof. C. Leibermeister, of Tübingen, in his lectures on the treatment of fevers, speaking of the use of the cold bath, says: "But this method is not only useful in abdominal typhus, but in every febrile ailment in which the temperature by its height and duration brings danger. The number of diseases is much larger than was formerly supposed. In those diseases in which exist severe and dangerous local alterations, is gained a great deal when we succeed to conquer the danger solely dependent upon the fever." In the January number of *Braithwaite* for 1873, Dr. Henry Thompson, physician to the Middlesex Hospital, reports the successful treatment with baths of a case of acute rheumatism with head symptoms. He mentions, incidentally, that the patient had severe and extensive complications—including pneumonia, pleurisy, bronchitis, and pericarditis—which underwent no perceptible change for the worse in consequence of the treatment adopted. Dr. Thompson considers that in these cases a high temperature is the index of some profound and damaging impression upon the nervous system. With regard to the value of cold applications in the treatment of this disease, he says: "There be many factors at work all conspiring together to compass the death of the patient. If the aggregate of these factors be overwhelmingly strong, there is an end of the matter and the patient dies; but let the powers of life and death be more evenly adjusted, then the removal of any single factor (say the temperature) turns the scale in favor of life, or, to use a more homely metaphor, takes off the last ounce that is breaking the camel's back. It behooves us, therefore, practically to accept the dogma that it is the heat which is the main destructive element, and to act upon it at the bedside whether we believe it or not. We can control temperature, and we are bound to control it." He considers a temperature of 105 or over to call for a prompt use of the bath, and uses it even at a lower temperature to palliate delirium and restlessness. The perusal of these reports leads me to contribute some notes of a case which came under my treatment last summer.

M., 41, native U. S., teamster in government employ. Admitted to hospital August 24, 1872. Had a slight attack of rheumatism five years ago. Is a hearty, well-nourished man; drinks some. August 21, was taken with severe pain in right knee and ankle, and had some fever. Has continued to get worse, and applied for treatment this morning. His right ankle and knee and both wrists are swollen, red, and painful. Tongue moist, furred. Skin perspiring freely. Bowels constipated. Pulse 98, full; temperature at 7 A. M., 101°. Heart sounds normal. No pain in chest. ℞ Sodæ and pot. tart. ʒ i.; Antim. and pot. tart. grs. ij. Mix in water and take at one dose. The affected joints to be wrapped in flannel and oiled silk, and kept wet with Fuller's sol. of bicarb. potass. and opium. Diet, beef-tea and milk. Bowels were freely moved. August 27.—Pain has left the ankle during the night; is worst now in the shoulders. Suffered severely last night, but was relieved by 10 grs. Dover's powd., and obtained some sleep. Urine high colored; no albumen. Takes food well. Temperature in evening, 103¾°; resp., 30. Sept. 1.—Passed a restless night. Has pain in testicles; they are tender and swollen. Says he has a dull pain over region of heart. Resp., 42; temperature, 103°. At 7 A.M., area of heart's dulness slightly enlarged. On auscultation a to and fro sound is heard. Two wet cups applied over region of heart, which gave some relief. Sudamina, chiefly over chest. He is very feeble and depressed. Quinia, grs. 5 every four hours, 10 grs. Dover's powd. at night. Six oz. brandy a day. Sept. 5th.—Patient continues much prostrated; delirious for 24 hours. The area of the heart's dulness extends above to second intercostal space, and laterally from near the right edge of sternum to beyond left nipple. No friction sound. The temperature is 105¾° at 7 A.M.; resp., 44. At 9 A.M. he was placed in a bath at the temperature of 54°, and kept in it 40 minutes, when the temperature was lowered to 101°. While in the bath he complained of cold. In the afternoon the temperature began to rise, and the bath was again used for 24 minutes, when the temperature fell to 100°. The patient then went to sleep. Sept. 6.—The patient feels easier. Temperature, 100°; resp., 37. Sept. 9.—Is stronger, and takes more nourishment. Sept. 14.—Area of heart's dulness diminishing; continues to improve. Sept. 20.—He is convalescing.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Notes of Practice and Peculiarities of Treatment.

BURNS.

The remedies used in the treatment of this class of accidents are as numerous as the visiting surgeons and house surgeons are disposed to devise.

Common white paint kept continually spread on the surface is a remedy quite commonly used.

Equal parts of Garland's cerate and sweet oil is a remedy favorably known.

A very satisfactory remedy is Dr. Buck's burn-mixture. The following is the formula for its preparation:—

℞. Gum Tragacanth..... ʒ ij.
Gum Acacia..... ʒ iv.
Molasses,
Aqua..... āā j

Mix the gum and water, and let them remain until thoroughly dissolved, and then add the molasses.

This is spread over the surface with a brush, forming a continuous coating, and if removed by the process of suppuration, it is to be immediately re-applied.

Syr. Acaciæ, with sufficient glycerine to make a liquid which can easily be spread, is sometimes used, and then covered with lycopodium.

SPRAINS.

The immovable apparatus is usually applied at once.

Immersing the limb in hot water, permitting it to remain for some time, and then applying a snug roller, is a most excellent method of treatment.

ERYSIPELAS.

A single case of erysipelas attacking an injured limb was treated by the immersion plan.

The limb was kept immersed in lukewarm water constantly for ten days, with exceedingly gratifying results.

Whether this method of treatment will be retained or not can only be determined by further use.

CHRONIC SYNOVITIS OF THE WRIST JOINT.

Dr. Burchard, one of the staff of the 2d Surgical Division, has devised a simple apparatus for applying

extension and counter-extension in these cases, which is very efficient, and productive of results satisfactory to the patient.

The indication is to entirely prevent the articular surfaces of the joint from coming in contact.

This indication is fulfilled by means of a wide palmar splint extending from the middle of the fore-arm to three or four inches beyond the fingers, narrowing as it passes beyond them.

At each corner of the upper end of the splint is a small slot. At the lower end of the splint is a round hole of a size proper to receive a violin key.

The splint is then padded in such a manner as to accommodate the irregularities of the limb.

Adhesive straps are now applied to the fore-arm, doubling upon themselves so as to form loops, passing from below upwards.

These loops are attached to the slots in the upper corners of the splint by means of tapes. This fastens the splint at its upper extremity. A broad band of adhesive plaster is next attached to the dorsum of the hand, passes a convenient distance below the fingers, doubles upon itself, and is attached to the palmar surface of the hand.

A small piece of board is then placed in the termination of this loop, in which a hole has been pierced for the reception of a piece of cat-gut, which is to pass out and become fastened to the violin-key.

The broad loop is then cut through in places corresponding to the interdigital spaces, and each finger-basket strapped, leaving the loop in its connection with the ends of the fingers intact.

The violin-key can now be turned, and any amount of extension made which may be desirable.

This apparatus is easily controlled by the patient, and the relief which it affords is sufficient guaranty that its application will be faithfully adhered to.

PNEUMONIA.

In my former note upon pneumonia I mentioned the plans of treatment which are adopted in this hospital. Since that time some cases have been treated by the quinine plan, 5 grs. three times a day, with excellent results.

There is one item in the management of patients who are the subjects of pneumonia which is of practical value, and that is, to insure perfect rest and quietude in bed until the disease has completed its course.

Occasionally patients die very suddenly in the progress of the disease, apparently, at least, from a failure in the heart's action incident to over-exertion, even as moderate as that which may be induced by simply getting out of bed.

That patients sometimes die very suddenly in the course of pneumonia has been noticed for some time, but the *rationale* of the untoward event has not been fully and satisfactorily given.

BRIGHT'S DISEASE.

It is believed that the occurrence of the severe nervous symptoms sometimes seen in connection with this disease, such as convulsions, can be warded off by the introduction of a proper plan of treatment.

The plan adopted is the diuretic plan, and consists in the administration of infusion of digitalis and bi-tartrate or acetate of potash.

These patients take half-ounce doses of the infusion three times a day, with varying doses of the acetate or bi-tartrate, and these remedies are continued for weeks or months in succession.

No hesitation is had with regard to these doses of digitalis, and in many cases very much larger quantities are given without any deleterious results being realized.

Not long since, however, a patient died in the water-closet, and at the post-mortem nothing was found to satisfactorily explain his sudden death.

The heart was hypertrophied, weighing ℥ xx, without valvular lesions, and coronary arteries normal. The kidneys were affected with chronic diffuse nephritis, which had gone on to the formation of a goodly number of cysts of variable size, from a filbert down.

Brain, normal.

Larynx, normal.

Lungs, normal. Some old pleuritic adhesions.

This man had been taking infusion of digitalis in half-ounce doses three times a day, and in the absence of any pathological lesion which would explain the sudden death, the cause was a question to be considered.

Nine of the house staff seemed to be unwilling to believe that death was produced by the digitalis, for two reasons: First, it did not accord with the experience afforded by the treatment of similar cases with the same remedy, and in much larger doses; second, that the article furnished in the institution is so poor that almost any one could take such doses with impunity.

The question, however, is not altogether unimportant.

SUB-ACUTE RHEUMATISM.

For the relief of the stiffness which remains about the joints, after an acute attack, the oleate of mercury and morphia is somewhat employed, and with very gratifying results.

The attention of the profession has been called to this compound by its author, in an article published in the last number of *Braithwaite's Retrospect*, where a more complete description can be found. Ringer also mentions it in his work upon therapeutics.

FROST-BITES.

A most interesting case has been in the hospital for some time, the interest involving the adjustment of a most important surgical question. In this case spontaneous amputation of the terminal phalanges had already taken place.

Spontaneous amputation of the long phalanges had almost taken place, and the question arose as to which was the proper method of management: to have the amputation to go on spontaneously a little farther, then disjoint the bones and remove them, trusting to granulations; grafting, in short, cicatricial tissue to cover the stump, or to amputate with the knife farther back, so as to secure original skin structure for a flap to cover the stump.

The reason given for a knife amputation, and the formation of a flap from the original skin, was, that cicatricial tissue is always easily irritated when subjected to pressure, as it inevitably must be, more or less, in a stump; and hence would be the source of constant trouble to the patient in the future.

The case was left, however, to heal by granulation and cicatrization, and the soundness of the procedure can only be determined by future observation.

PREPARED EARTH.

This material is used in dressing surfaces which have a gangrenous offensive discharge, like the sloughy surfaces following frost-bites.

The earth is spread upon a cloth, and wrapped about the sore, and will remain twenty-four hours without becoming very offensive.

The material is specially prepared at Philadelphia,

and can be obtained for the nominal sum of $3 per bbl.

I suppose that any clayey earth, perfectly dried and thoroughly pulverized, will answer the purpose equally well.

STRANGULATED HERNIA.

A case of this kind was brought into the hospital a few days since, of sufficient age to give evidence that peritonitis had already commenced.

The hernial tumor being somewhat distended, Dr. Van Wagenen procured an aspirator, with which the tumor was emptied of its serous contents. After this operation the hernia was reduced with the utmost ease, thus avoiding the cutting operation.

The patient subsequently suffered from complete suppression of urine, and died somewhat suddenly.

Post-mortem examination revealed the fact that the intestine involved in the hernia was in a perfectly healthy condition, and there were no evidences of peritonitis.

Edœma of the lungs was found, which was considered as the probable immediate cause of death.

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, April 15, 1873.

THE MEDICAL AND SURGICAL HISTORY OF THE WAR OF THE REBELLION.*

THESE two splendid volumes are before us. They comprise the first parts of the Medical and Surgical History of the late war, respectively, and we need not say that, while they have been anxiously looked for, they are most cordially welcomed by the profession. It has been thought better to announce the introductory volumes of this great national work, in an editorial, rather than under the form of a review or bibliographical notice.

Being magazines of facts, statistics, and deductions, and in truth reviews and compilations of the writings, reports, statements, and data of a multitude of independent observers, it appears more appropriate to make such observations as we have to offer, under this form, rather than in the ordinary way of review or notice.

The stupendous array of figures, and the variety and number of recorded facts which they contain, while they reveal the character and quality of the individual labor and discipline requisite for their elucidation and presentation in elegant and intelligible shapes, serve as a warning to the rash reviewer who should attempt an independent analysis with the idea of picking flaws or discovering discrepancies.

The separate departments are introduced by prefatory notices from Surgeon-General J. K. Barnes, U. S. A., which acknowledge the liberality of the Government in providing means for their publication, and make cordial and suitable acknowledgments to the medical officers, both regular and volunteer, for their zealous co-operation in furnishing the more or less crude material from whose almost primeval chaos this world of medical and surgical knowledge has been constructed, and irradiated with the light of intelligent selection, adaptation, and co-ordination. Due credit is given to the principal artificers, Dr. J. J. Woodward, U. S. A., and Dr. George A. Otis, U. S. A., whose analytical skill and discrimination, patient research, and self-sacrificing labor, together with their synthetical ability and reconstructive power, have resulted in the triumphant erection of the foundation upon which the finished edifice will speedily appear in all its completeness and beauty.

The first year of the war revealed the fact that the methods in use in the medical department of the army, and the traditions and usages of that branch of the public service, were wholly inadequate, incomplete, and obsolete. A revolution took place, and while the original form remained, and a few traditions, preserved in the minds of the older men, held sway, radical and thorough reforms were introduced, with the immediate effect of quickening into life and activity the small but able and well-disciplined body of men who composed the active members of the regular medical staff, and the large number of new officers who hastened from civil life to offer their services, and if necessary their lives, to the commonwealth.

The appointment of a young, able, and bold man to the office of Surgeon-General, and the aid afforded by the best members of the medical profession, many of whom had had military experience, corroborated and stimulated by an anxious and thoroughly aroused public sentiment, gave force and efficacy to these measures; and the immediate result was witnessed in the abundance of medical supplies, facilities for the transportation of sick and wounded men, splendid field and permanent hospitals, and intelligent methods of economizing and systematizing professional labor on the battle-field, securing returns, reports, and histories of cases, conveying immediate succor to the wounded and disabled, and providing for their ultimate care and attention till death, or more or less perfect recovery.

It is just to Dr. Wm. A. Hammond, formerly Surgeon-General, U. S. A., to record that the beginnings of these great changes and radical reforms were made under his administration, and that he confidently and intelligently looked forward to the great results which have flowed from them for the benefit of science and humanity.

It is also due to his successor to affirm that these measures have been ably and consistently supported and directed under the administration of Brig.-Gen. Barnes, both during the war and since its happy termination. Great credit is also due to Dr. John H. Brinton, of Philadelphia, late Surgeon U. S. V., who laid the foundation of the Army Medical

* Prepared in accordance with Acts of Congress, under the direction of Surgeon-General Joseph K. Barnes, United States Army. Part First, Medical Volume, 4to, pp. 726, and Appendix, 4to, pp. 365. Part First, Surgical Volume, 4to, pp. 650. Washington: Government Printing Office, 1870.

Museum, and made a commencement of the Surgical Department of the Medical and Surgical History. The method at that time adopted was found to be impracticable on account of the vast amount of labor it would entail, and it was in 1865 changed for the method as adopted and carried out in the works before us. Space does not permit the publication of the introductory chapters entire, and we do not see very well how any clear idea of their scope, and the reasons for the plans accepted and employed, can be given by extracts. The system adopted by Dr. Brinton contemplated a history by battles and campaigns, with enumeration of the forces employed, topographical description of movements of troops, with returns of killed and wounded, supplemented by recorded conditions of climate, weather, hygiean supplies and facilities for transportation, reports of operations and methods of treatment, and descriptions of wounds, injuries, diseases, and their results. The method adopted is a classification by regions of body and character of injury, with short personal histories and illustrations, and references to the Army Medical Museum. A chronological table of battles and engagements is furnished, with Federal and Confederate killed, wounded, and missing. In the medical volume tabulation of disease is made by regions of country and military departments, with reference to the influence of climate, locality, and temperature. Distinction is made in the tables between white and colored troops, and valuable facts are developed with reference to their relative idiosyncrasies and susceptibilities.

The figures of the Adjutant-General's office show the whole number of troops enlisted during the war to have been 2,073,112. The mean strength, 544,704, present; 196,803, absent—741,507, aggregate. The total number of deaths from disease included in the tables, which comprise officers and men both regulars and volunteers, was 166,623; of colored troops, 29,004—making an aggregate of 195,627.

The whole number of deaths amounts to 304,369. Of these, 44,238 were killed in battle, and 26,168 is the estimate of prisoners dying in the hands of the enemy.

Dr. Woodward concludes that his tables cover about nine-tenths of the class of facts they are intended to embrace.

The following is a consolidated table from Dr. Otis's introduction to the surgical volume:—

He states in explanation as follows:—

"The aggregate of 235,583 gunshot wounds here given, with resulting mortality of 33,653, or 14.2 per cent., is explained in the introduction to the medical volume to represent the total returned from about nine-tenths of the mean strength of the Union army, and to be exclusive of the injuries of those killed in action. The latter category (as has been just stated) embraces, according to the Adjutant-General, not less than 44,238; according to the alphabetical registers of the Surgeon-General's office, 35,408; according to the Chronological Summary, 59,860." In a note he states: "The chronological summary compiled by the faithful and indefatigable Chief Clerk of the Surgical Division, Mr. Frederick R. Sparks, indicates the following losses: *Union troops* killed, 59,860; wounded, 280,040; missing, 184,791. *Confederate troops* killed, 51,425; wounded, 227,871; missing, 384,281. The last aggregate includes the armies surrendered. Allowing for many exaggerations and omissions, the errors appear to balance remarkably, and the results to correspond with statistics derived from entirely different sources."

Classification.	White Troops.		Col'd Troops.		Total.	
	Cases.	D'ths.	Cases.	D'ths.	Cases.	D'ths.
1 Burns	9,487	94	613	4	10,100	98
2 Contusions	44,323	161	2,649	11	46,972	172
3 Concussion of brain	873	193	49	22	922	215
4 Compression of brain	61	17			61	17
5 Drowning		672		125		797
6 Sprains	38,387	3	4,317		42,704	3
7 Dislocations	2,908	9	108	1	3,016	10
8 Fractures	1,287	53			1,287	53
9 Simple fractures	4,215	61	131	15	4,346	76
10 Compound fractures	1,316	378	55	19	1,371	397
11 Gunshot wounds	229,119	32,731	6,466	922	235,585	33,653
12 Incised wounds	21,444	186	1,305	3	22,749	189
13 Lacerated wounds	14,153	459	595	8	14,748	467
14 Punctured wounds	5,285	191	499	8	5,784	199
15 Poisoning	3,087	93	67	17	3,154	110
16 Other accidents and injuries	13,099	1,003	2,174	72	15,273	1,075
Aggregates	389,044	36,304	19,028	1,227	408,072	37,531

He goes on to say:—

"However useful these approximations may be for many purposes, any anticipation that they may afford reliable guidance or much assistance in framing a surgical history of the war, must prove illusory. But the consolidation of the dates of the detailed quarterly surgical reports might be justly expected to furnish a very complete record of the surgical practice in the Union army during the latter two years of the war; and for the last year the classified return of wounds received in action should serve as a nearly accurate check list."

A second note is an answer to some of the strictures of Mr. T. Longmore, Deputy Inspector-General of the British army, which appeared in the 54th volume of the Medico Chirurgical Transactions, apropos of Circular No. 6 from the Surgeon-General's office, 1865. A little further on—page xvii. of the introduction—Dr. Otis says: "From a surgical point of view, there was no motive to exclude information that could be obtained of the Confederate wounded. *Le vrai chirurgien ne regarde pas l'uniforme.* Estimates of the ratio of wounded to the forces engaged and other attempts at approximations to unattainable numerical precision, were held to be very subordinate to the accumulation of the greatest possible number of practical surgical facts." This sentence is the key to the method pursued in arranging or classifying the vast mass of facts brought under observation. That the effort has

been wonderfully successful will, he believes, be the verdict of the profession throughout the world.

The conclusion of the introduction to the surgical volume contains a list of medical officers who were killed or who died through accidents in the direct line of their duty, and of those who were wounded in battle. Of this number, eighteen were killed in action. Thirteen were killed by partisan troops or assassinated by guerillas. Eight died of wounds received in action. Nine lost their lives by accident in the performance of duty, and seventy-three were wounded in battle.

This list of casualties, greater proportionally than that experienced in any other staff corps, should, as Dr. Otis justly observes, be sufficient to correct the popular fallacy that in time of battle the post of the medical officer is one of comparative freedom from danger.

It is a truth which all the officers and soldiers of the late war will support by their testimony that the Medical Staff yielded to none, whether in the line or staff, in coolness under fire, unhesitating acceptance of the situation irrespective of danger, privation, or hardship, uncomplaining fortitude, and faithful and heroic performance of duty. Some of them, indeed, in emergency did some *tolerably good fighting*, and, temporarily laying aside the green sash, acted as aides and staff-officers for their commanding generals. We never, however, heard of such services being mentioned in orders. The only return made was the private thanks of the general thus and often deeply obliged, and a slight increase of consideration when requests were made for additional facilities for the comfort and care of the sick and wounded. The dryness of tables and figures—which rise, however, to the sublimity of all that is great, heroic, tragic, and pathetic, when the conditions which their naked outlines represent are understood and considered—is compensated in the Appendix to the Medical volume which contains abstracts from the personal reports of medical officers, and the reports of the Medical Directors of armies, corps, and divisions.

These documents illustrate the real medical history of the war. They are most interesting and valuable historical records, and indicate a high degree of intelligence, not alone professional but administrative, military, and comprehensive. They show that the profession of the country, whether trained in the army, in metropolitan centres, or sparsely and recently settled districts, was capable of grasping and dealing with the great emergency in which the country found itself suddenly involved. They breathe the purest spirit of humanity irrespective of politics, and reveal a high degree of cultivation of both mind and heart. They indicate a degree of medical culture beyond what we are apt to acknowledge in our periodical onslaughts on the medical colleges. More than this, they display the acute practical common-sense of the American *mind* which often rises to the level of genius. The war developed first-class soldiers and first-class military surgeons, out of what, at first sight, and to a European, would have seemed the most unpromising and even hopeless material.

We must conclude the present article reluctantly, for want of space, by recommending to the American Medical Association, at its next meeting in St. Louis, to petition Congress for an appropriation sufficient to publish an edition of the Medical and Surgical History, large enough to place a copy in the hands of every medical officer and private physician who served in the late war, and also to furnish copies for sale at cost. We think a vote of thanks should be passed to Congress for what it has done, and that measures should be adopted to express, in some tangible and emphatic manner, the sense which the profession of medicine entertains for the invaluable services of the learned and accomplished compilers and editors of this great work. We do not endeavor on this occasion to draw any practical conclusions from the facts and figures presented. The completed history (two more volumes in each department are to follow in due season) will be a mine for research and reference to those engaged in special studies and in estimating the value of particular operations and surgical procedures, as well as of medical pathology and the history of disease. We may assume that, in such a vast mass of statistics, special and peculiar conditions will to a great extent balance one another, and that numerical results will, at least, closely approximate exact truth. The sense of the profession educated in civil life and of that department of the profession which has had military experience on a large scale, will, we think, be found to harmonize with the results of the statistics, and the value of probability in forming a judgment in a particular case will be greatly enhanced and become a guide, encouragement, or conservative correction, as the circumstances may demand.

Another important point consists in the fact that this treasury of fact and recorded experience will serve together with other works of the same nature, to inform and instruct the profession in such a manner that it will be prepared to cope promptly, energetically, and intelligently with the catastrophes of future wars, if such should unhappily arise.

An admirable work could be constructed out of these materials as a text-book on military medicine and surgery, and if such should be done it ought to be a compulsory text-book in every medical college. We hope, finally, that these volumes, so honorable to the profession throughout the country and to the Medical Bureau of the United States Army, will have their legitimate influence upon statesmen, legislators, and professed politicians, and cause them to recognize the claims which *legitimate* and *catholic scientific* medicine has upon just and equitable legislation. To recognize the fact that no

sect in medicine could have approximated these results, that science and humanity go hand in hand, *that quackery is an immorality*—that the defence, support, and encouragement of legitimate organized medicine is essential to the good order of society, national prosperity, the happiness of individuals the honor of the country, and the perpetuity of the institutions which the profession of medicine has thus given irrefragable evidence of its zeal, learning, skill, courage, and self-sacrifice in upholding and maintaining.

We have, on a former occasion, ventured the opinion that the Army Medical Museum, in addition to its function, strictly pathological and illustrative, had served as a warning to our lawgivers, and had had an influence in favor of arbitration instead of war. The study of the work before us will intensify that impression, and we recommend it from that point of view to statesmen and *able editors*, in the hope that hereafter all possible expedients, consistent with honor, will be exhausted before recourse be had to war.

If the dark and terrible side of the picture of the pomp and circumstance of glorious war, which these calm statistical scientific books present, can be appreciated, and exert their influence in accomplishing such a result, it will be a greater triumph for the profession than that achieved by their extraordinary merit.

The illustrations and maps are remarkable for their excellence, correctness, and beauty, and the typographical execution is in the highest style of the art.

Reviews and Notices of Books.

HAND-BOOK OF PHYSIOLOGY, by WILLIAM STENHOUSE KIRKES, M.D., edited by W. MORRANT BARKER, F.R.C.S., etc., with 248 illustrations. Eighth edition. Philadelphia: Lindsay and Blakiston. 1872. Pp. 835.

THIS edition is in great part a reprint of the one of 1869, the changes made having slightly lessened the number of pages, but, on the other hand, have considerably increased the value of the work, since by them it is brought quite up to our present knowledge of the science. The reduction in size (less than ten pages) has mainly been caused by the omission of matter relating to questions which, at the date of the seventh edition, were still under discussion, but are now considered to be settled. Nearly every chapter in the first part of the book has undergone more or less change, and additions more important than extensive are frequently to be met with; for example: new matter has been introduced into the chapters relating to the chemical composition of the blood; the leucocytes and their movements within and through the walls of the vascular system; the phenomena of the heart's action; the mucous membrane of the alimentary tract, and the one on animal heat. Paragraphs have been added treating of the tests for biliary salts; of the formation of glycogenic matter in the liver; and a very considerable addition which has been made to the article on the physiology and anatomy of the lymphatic system includes our present knowledge of its vessels, spaces, and glands. The histology of the spleen is for the first time mentioned, and in speaking of the skin, its function in regulating the heat of the body is likewise introduced with this edition. Under the head of the nervous system we find new matter relating to the physiology of the facial, pneumogastric, spinal accessory, and vaso-motor nerves, and the description of nerve fibres has been much improved.

We also observe that several statements have been retained which might, we think, have borne modification; among them we mention the one which classes the nipple among the tissues whose erection is due to vascularity; also the statements that when one kidney is removed its fellow becomes enlarged, and that when the inhibitory influence of the par-vagum is suspended the heart's contractions become *stronger*.

On the whole, there is very little in the book which either the student or practitioner will not find of practical value and consistent with our present knowledge of this rapidly-changing science; and we have no hesitation in expressing our opinion that this eighth edition is one of the best hand-books on physiology which we have in our language.

AIDS TO THE DIAGNOSIS OF DISEASES OF THE KIDNEYS, by W. R. BASHAM, M.D., F.R.C.P., etc. Philadelphia: Lindsay and Blakiston. 1872.

THIS book is a collection of sixty nicely-drawn figures, with forty-eight pages of descriptive text; the illustrations containing examples of all the most typical pathological and extraneous objects found in the albuminous urine from forty-one patients. Short and succinct accounts of the latter are given, together with the general character of the symptoms, their duration, and, in all cases where it could be ascertained, the termination in death or recovery. In many of the fatal cases, the lesions found *post-mortem* are mentioned, but little or nothing is added in the way of comment or theory on the part of the author, so that the book is a bare statement of clinical facts, and, as such, will be of value to every physician who uses the microscope in his practice. The only uncomplimentary thing we can say of the book is, that on page twenty-eight an error occurs which ought not to have crept into a book of such dimensions, viz.: the reference to fig. 3 is evidently out of place, and fig. 4 and fig. 5 should read instead fig. 3 and fig. 4. In all other respects we are well pleased with it.

FAMILY THERMOMETRY. A Manual of Thermometry for Mothers, Nurses, &c.—By EDWARD SEGUIN, M.D. New York: G. P. Putnam & Sons.

DR. SEGUIN, already well known to our readers by his useful abridgement of Wunderlich's treatise on the thermometer, continues to pursue his favorite subject in a new field, subordinate, but, in the writer's estimation, not less important than that of the use of the thermometer by physicians. This concerns the habitual employment of this instrument, by intelligent non-medical persons having charge of the sick, in the intervals of physicians' visits. Dr. Seguin urges the necessity of regularly *training* such persons in the art of measuring temperatures, with an emphasis that is sometimes a little fanciful, and also often eloquent. He takes "mothers as types of the women who devote themselves to men from birth to death," and describes the indignation or despair with which those who are once alive to the importance of their task, may (perhaps more properly, *should*), recognize their present unfitness for it. "Seeing everything around them co-ordinated according to certain laws,—they wonder how it happens that they alone in their professional capacity of breeders of men, have no rule to abide by. . . Re-

flecting upon their own present status in the field of labor, and upon the incommensurable value of the products of their loins and vigils, women cannot suppress their apprehensions, or disgust, at being obliged to raise our children in health or in disease, without having been taught how to do so."

The manual essentially contains: 1st. A general explanation of the effect of disease in modifying the temperature of the body. 2d. An explanation of the method of recording these variations by the thermometer. 3rd. Certain details of prognosis, based upon these variations. 4th. Various practical suggestions for the use of heat and cold in domestic practice, in sudden emergencies or in the absence of a physician. Under each of these heads the author says much that is good, and also some things that we should criticise. It is good that women be accustomed to apply the thermometer at the first sign of illness, and record the observation for the future reference of the physician; but it is surely an exaggeration to tell them that "the thermometer is the only guide," and that "all diseases are *ustorius*." Equally unsafe to permit them to form a prognosis from rise of temperature alone, for how shall they distinguish between the significance of the hyperpyrexia of a continued fever, and in the paroxysm of an intermittent or of an insignificant inflammation, as a furuncle, that in children so easily determines high fever? Again, we do not see the advantage of substituting a special thermometer, with a norme of health, for that in ordinary use, on the ground that "the melting point of snow, or the freezing point of mercury, has no interest for a mother, since they are far remote from the range of health, disease and death." On the other hand many of the categoric propositions are of real value to women sufficiently intelligent to appreciate, and sufficiently sensible not to be encouraged by them to amateur meddling." Heat is the most integral expression of life." "Life is secure when the production and consumption of heat are balanced." "Allay consuming heat." "Recall or accumulate departing heat." "Quench the thirst even of him who cannot drink,—feed through whatever channel him who has no stomach." "Remedy by external appliances, unequal distribution of heat." "The kettle has cured more cases of croup than medicines." "When a child is confined to school-rooms, crowded dormitories or manufactories, his mother must at every opportunity study his temperature."

We sincerely commend Dr. Seguin's book to the class of mothers for whom he writes it.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, January 25, 1873.

Dr. Ellsworth Eliot, President, in the Chair.

NEW MEMBERS.

The following gentlemen, recommended by the Comitia Minora, were granted certificates of membership:—Beverly Robinson, 39 W. 35th st., a graduate in Medicine at the University of Paris, France, in 1872; Albert H. Buck, 50 E. 31st st., a graduate in Medicine at the Col. of Phys. and Surg., Med. Dep. of Columbia Col. in 1867; Thomas E. Satterthwaite, 50 E. 31st st., a graduate in Medicine at the Col. of Phys. and Surg., Med. Dep. of Columbia Col., in 1867; Read J. McKay, a graduate in Medicine at the Bellevue Hosp. Med. Col., in 1867; Charles Y. Swan, Astor House, a graduate in Medicine at the Col. of Phys. and Surg., Med. Dep. of Columbia Col. in 1856; Jacob F. Howe, 52 Great Jones st., a graduate in Medicine at the Col. of Phys. and Surg., Med. Dep. of Columbia, Col. in, 1871; William F. Gellhar, a graduate in Medicine at the New York Med. Col., in 1864.

DEATH OF MEMBERS.

The President then announced the death of the following members of the Society:—Lewis Tice, M.D., a member since April 22d, 1872, who died at his residence in this city, Dec. 23d, 1872, aged forty-five years. Dr. Tice graduated in Arts at Union Col., Schenectady, N. Y., in 1848, and in Medicine at the University of the City of New York, Med. Dep., in 1851.

Dr. Guillermo Michelena, a member of the Society since Nov. 25th, 1872, died at his residence in this city, Jan. 15th, 1873, aged fifty-six years. Dr. Michelena graduated in Medicine at the Univ. of Caracas, Venezuela, in 1840, and at the Univ. of Paris, France, in 1847. He was head Surgeon of the Charity Hospital in Caracas for fourteen years; Rector of the Univ. of Caracas for three years; Professor of Obstetrics and Surgery in the same institution for three years; member and censor of the faculty of the same; M.D. by examination at the Univ. of Havana, Cuba, and President of the medico-legal society of Havana.

REPORTS OF COMMITTEES.

Dr. Castle, of the committee on intelligence, made a report on the progress in the department of Obstetrics and Gynæcology.

Dr. Russel, Chairman of the Committee on Diseases, then reported through Dr. A. B. Judson, the following facts regarding the sickness and mortality from various causes in this county during the year 1872, the report being accompanied with charts. During the period mentioned there were reported to the Bureau of Sanitary Inspection of the Health Department, 157 cases of *typhus fever*; 616 of *typhoid fever*; 3,037 of *scarlatina*; 1,259 of *measles*; 714 of *diphtheria*, and 2,386 of *small-pox*.

"The mortality of the year 1872, as we anticipated in a former report, was very excessive; being nearly 5,500 over that of any previous year in this city. A better idea of the sudden increase by which it was marked, will be conveyed by the following figures, extending back for ten years:

Deaths in	1863,	25,196.
"	1864,	25,645.
"	1865,	24,843.
"	1866,	26,815, (1,158 from cholera.)
"	1867,	23,159.
"	1868,	24,889.
"	1869,	25,167.
"	1870,	27,157.
"	1871,	26,976.
"	1872,	32,647.

Up to 1866 the death rate of these years was considerably augmented by the fatality attending wounds and diseases contracted in the war of the rebellion. In 1867 there was a marked decrease to 23,000 deaths, and from that time up to 1870 the increase was progressive. In 1871, a very healthful year, there was a slight diminution, and in 1872, an enormous rise in mortality. We shall compare the deaths in 1872 with those in the preceding year, in order to show that particular diseases were concerned in this increase. The peculiar influences, meteorological or otherwise, which contributed to so large a mortality, are not alto-

gether apparent, as the rise in weekly mortality began to be noticeable in the very beginning of the year, and continued to the end. Such causes were certainly not confined to this city, as every large eastern city from which we have yet received returns, participated to even a greater extent in the same trouble. During 1872, as compared with 1871, the increase in Boston was 34 *per cent.*; in Providence and Philadelphia 28 *per cent.*; in Brooklyn 23 *per cent.*, and in New York only 21 *per cent.* That of Cincinnati was normal —about 6 *per cent.* A large territory along the Atlantic was thus overspread by the same disturbing elements. The summer's heat was certainly remarkable, and its humidity high, to which circumstances we may attribute much of the mortality of the hot season and early autumn; but the meteorological phenomena of the rest of the year offered no features extraordinary enough to account for the unwonted death-rate.

The zymotic class of affections produced 8,364 deaths during 1871—31 *per cent.* of the total; and 11,922, in 1872—37 *per cent.* of the total; an excess of 3,558 deaths, or of 69 weekly. Every important disease of the miasmatic group shared in this increase save *relapsing fever*, whose mortality in both years was so trifling as to warrant its exclusion from the list which we now present:

DEATHS FROM	1871.	1872.
Small-pox	805	927
Measles	409	463
Scarlatina	791	990
Diphtheria	238	446
Croup	466	675
Whooping-cough	465	565
Typhus fever	65	86
Typhoid fever	239	364
Typho-malarial fever	12	25
Intermittent fever	110	111
Remittent fever	165	193
Cerebro-spinal fever	48	782
Puerperal fever	80	117
Diarrhœal diseases	3,653	5,197

It will be perceived from the foregoing that the three most fatal epidemics of the year were those of scarlatina, small-pox, and cerebro-spinal fever. We may regard scarlatina as our most constant epidemic, and its mortality in 1872, although greater than in 1871, was not up to the average. If we accept as an approximation to the truth the number of *cases* reported to the Bureau of Sanitary Inspection, its mortality approached 32 *per cent.* 725 of its deaths occurred among children less than five years of age; 193 between five and ten; 38 between ten and fifteen, and 34 among those over fifteen years; the oldest being a male between forty and fifty. Of all the deaths from this cause, 667 took place within the first six months of the year.

The epidemic of *small-pox* was a continuation of that of the previous year. It reached its culmination in the spring, its highest weekly mortality having been 51 in the week ending May 25th. It abated during the summer months, and continued under control afterwards. 552 of its victims were males, and 377 were females. It exhibits a greater disparity between the sexes, chiefly among adults of foreign birth, than any other disease. This is doubtless owing to the better facilities for revaccination enjoyed by the females of the poorer classes over their male relations, who are commonly absent at work during the visits of the vaccinating physicians. 552 deaths were of natives and 377 of foreigners. The great preponderance of native deaths is to be accounted for by the fact of 409 having occurred in children under ten years old, the vast majority of whom were of native birth although of foreign extraction. There were retained in the city 617 cases which came to the notice of the health authorities. 316 of these, or over 50 *per cent.* proved fatal. Many of these were only discovered by the certificate of death, and of course many who recovered had been sequestered, and thus escaped observation. Therefore the ratio of deaths given must be regarded as exaggerated. The 11th and 17th wards suffered the most severely, having respectively 60 and 78 deaths, 44 *per cent.* of all which occurred in the city proper, out of 17 per cent. of its entire population. Four persons between 70 and 75 years old, and one between 80 and 85, were carried off by this disease.

Cerebro-spinal fever became epidemic early in the year, and up to December 31st destroyed 782 lives. The first death from this cause in New York was recorded in 1861—or, at least, "spotted fever" was assigned as the cause of death in a single instance. No similar case was recorded until 1866, during which year there were registered 18 deaths from "cerebro-spinal meningitis." The same disease was credited with 32 deaths in 1867; with 34 in 1868; with 42 in 1869; with 32 in 1870, and with 48 in 1871. Most of these cases seem to have been regarded as *idiopathic* cerebro-spinal meningitis, if there be such a thing. The proportion of deaths to cases of this disease, as it prevailed here during the past year, cannot even be estimated, as we have had no means of ascertaining the number of recoveries. 415 of its deaths were in males, and 367 in females; 642 of native, and 140 of foreign birth. The same explanation of the excess of native mortality is applicable to this affection as to small-pox, 530 deaths, or 68 *per cent.* having occurred among children under ten years old. After that age the number diminishes rapidly in each successive quinquennial period of life—the two oldest deaths having been reported as between 65 and 70. As to the etiology of this disease, the circumstances of its first cases, and many subsequent ones having been found in dwellings where defective drainage existed, seemed to point to emanations from privies and sewers as its chief exciting cause. Its appearance, however, almost simultaneously in many portions of the United States would indicate a pandemic origin. But we do not deem it expedient to discuss theories.

There is nothing of interest to be noted with regard to the deaths by *measles* and *croup*. *Diphtheria* was particularly fatal during the latter portion of the year; its deaths in the last quarter averaging 21 weekly.

261 males and 304 females fell victims to whooping-cough. There are two interesting facts which distinguish the fatal cases of this affection in New York, viz.; 1st, its being confined *exclusively* to children under 10 years old, no cases in persons beyond that age having been recorded since 1865, and in that year but one, whose age is given as between 50 and 60. We have before adverted to the universal preponderance of females over males among the fatal cases of this disease, as quite characteristic. The United States Census, for 1870, shows 3,987 deaths of males against 5,021 among females, from whooping-cough, throughout the country. Of these 9,008 cases only 143 were over 10 years old, one of which was over 80 years. The remaining diseases of this order exhibited no unusual peculiarities, except in the case of *diarrhœal affections*, which produced an enormous mortality during the hot season. That our excessive summer mortality is due almost entirely to heat, is shown pretty well upon the chart

which accompanies this report, where the fluctuations of the death-line are seen to correspond closely to those of the line of mean temperature.

Syphilis caused 139 deaths, of which number 110 were congenital cases. It is somewhat curious that of the latter, 63 were males and only 37 were females.

Six deaths were due to *hydrophobia*.

Alcoholism was returned as the direct cause of death in 314 instances. In 1871 deaths from this cause amounted to 220. Of the last year's deaths *delirium tremens* occasioned 102. Intemperance was certified to be either the direct or complicating cause in altogether 826 cases—over 2 daily. Seventy-five *per cent.* of the cases were in males.

Constitutional diseases caused 6604 deaths against 6263, in 1871. The principal ones were as follows:—Four deaths were due to *gout* (2 males and 2 females); and 152 to *rheumatism* (62 males and 90 females). The latter affection has steadily been increasing in prevalence and fatality within the five years past. To *cancer* were referred 392 deaths, against 335 in 1871. Cancer of the uterus caused 95; of the stomach, 87; of the breast, 55; of the liver, 48. Of the cancers of the breast and uterus, 74 occurred in married women, 56 in widows, and 11 in single women. Of the whole number of cases, 96 were natives and 296 foreigners; a remarkable difference in favor of the native element, obtaining equally among males and females, for we find that cancer of the liver destroyed 24 of each sex, of whom but 6 were natives.

Tuberculous and *scrofulous affections* caused 6023 deaths. The most interesting of this order, viz.:—*phthisis pulmonalis* carried off 4274 persons—13 per cent. of the mortality from all causes—its lowest relative mortality since 1866. In 1871 its deaths amounted to 4186—a percentage of 15.5 of the total. Of the deaths caused by it in 1872, there were 2176 males and 2098 females; 1461 were natives and 2813 foreigners—the latter being about double the former.

The class of *local affections* occasioned 10,903 deaths, against 9,280 in 1871. The chief varieties were as follows:—Disorders of the nervous system, 3479. Of these *cerebral meningitis* and *encephalitis* caused 962; *apoplexy* and *paralysis*, 577; *insanity*, 65; *epilepsy*, 94; *convulsions*, 922; and direct effect of *solar heat*, 320. The last is the greatest number of deaths from this cause ever known in New York. 212 occurred during the week ending July 6th. In point of mortality from all causes (amounting to 1591) the week mentioned was the most remarkable one in the history of this city. Upon a single day, July 2nd, there occurred 351 deaths. It will be seen by referring to the chart that the highest mean temperature was reached on July 1st, and was immediately followed by a corresponding rise in the death-rate.

Of disorders of the circulatory system, *aneurism* (mostly aortic) caused 72 deaths, and *heart diseases* 894.

Diseases of the *respiratory system* caused 3,649 deaths, against 3,248 in 1871. Of these, bronchitis was credited with 1,040, and pneumonia with 2,150. The latter disease was so prevalent during the first half of the year as to almost assume the character of an epidemic, 1,393 of its deaths having occurred in that period. One-half of its total mortality was among children less than five years old.

To affections of the digestive system were ascribed 1,330 deaths, of which the principal were: *diseases of the liver*, 478; *enteritis* and *gastro-enteritis*, 321; *gastritis*, 118; and *peritonitis* (idiopathic, so called), 146.

Urinary affections were credited with 1,174 deaths, 1,064 of which were due to *Bright's disease*. *Nephritis* and *uræmia* caused about the same number as in 1871. *Diabetes mellitus* was assigned as a cause in 25 instances—16 males and 9 females. Singularly enough the same number of such deaths, and the same proportion between the sexes, was observed in the previous year.

Diseases of the generative system produced 59 deaths; of which 26 were cases of *ovarian tumor* or *dropsy* not operated upon, and 10 of *metritis* (non-puerperal).

Diseases of the locomotory and osseous systems caused 159 deaths: and affections of the integument, 40.

Affections peculiar to new-born children were credited with 965 deaths—635 being credited to *premature* or *abnormal births*; the rest being mostly *malformations*.

Diseases of the puerperal state caused 476 deaths, against 381 in 1871.

Age was certified to have caused 393 deaths, 7 of which (1 man and 6 women) were reputed to have passed 100 years—cases somewhat apocryphal.

There were due to accident or negligence, 1,108 deaths, 219 of which resulted from *drowning*; 116 from being *run over*, and 305 from *falls*. There were 69 homicides, but no executions. Of the 144 suicides, 50 were by *poison*, 32 by *shooting*, 22 by *hanging*, 16 by *cut* or *stab*, and 13 by *drowning*.

Of the total mortality, about 50 *per cent.* was in children less than 5 years old. There died 1,553 persons of 70 years and upwards. The total number of deaths was 32,647, giving an annual death-rate of 32.6 in each thousand inhabitants, the population being estimated at one million.

THE PAPERS OF THE EVENING.

Dr. T. Addis Emmet read to the Society a paper on "Laceration of the Perineum involving the Sphincter, and Operation for Securing Union of the Muscle." The whole paper has been published under the head of *Original Communications*.

Dr. Bozeman, being called on by the President, expressed his satisfaction at the able manner in which Dr. Emmet had presented the subject of extreme lacerations of the perineum, and had little to add excepting in relation to the treatment of lacerations, which also involved the recto-vaginal septum, which Dr. Emmet had not fully touched upon. The extension of the rupture into the septum adds very much to the gravity of the accident, and increases very considerably the chances of failure in an operation. This had been the case in his own early operations, and it was not until later that he learned that it was owing to the attempt, on the part of the operator, to accomplish too much at once, viz.: to close both the fissure of the septum and of the perineum at the same operation. For fifteen years past he had followed the plan of making two stages, closing, first, the septum, and, after an interval of five or six weeks, the perineum. He complimented Dr. Emmet upon the success which resulted to him in the use of the interrupted suture, which was one of the earliest forms of suture employed, and was still the favorite with many of our most skilful operators. For himself, however, he preferred the quilled suture of Dr. Roe, which was, also, the one chiefly in use in England, especially by Mr. Baker Brown, whose success in the use of it had not been excelled by any other form of producing union.

Dr. Bozeman had himself employed at the outset of his experience the interrupted suture, but had suffered

so many failures as regards the union of the recto-vaginal septum, that he had adopted the quilled suture instead. With the perineum his success with the quilled suture had been much better. Dr. Pancoast had also complained of this difficulty in all his early operations.

Dr. Bozeman was of the opinion that for practical purposes, the quilled suture was to be preferred to the one described by Dr. Emmet. When it is used, as in any case, great care needs to be paid to the paring of the edges of the rupture. It is his custom to make the denuded surface from one-half to three-fourths of an inch broad, in order that by the extensive apposition all passage for flatus or fæcal matter might be cut off.

Where Dr. Emmet uses four or five sutures, Dr. Bozeman is accustomed to employ only three. The first one is employed in very much the same manner as the first one introduced by Dr. Emmet, though brought out differently and in a manner which he would not then undertake to describe. It should be introduced an inch from the denuded surface and almost on a level with the anterior margin of the recto-vaginal septum, and brought out two or three lines from the median line. The second suture he would place about two-thirds of an inch above the other, and a short distance outwards; the third in a line with these, or at an angle of nearly 45° with the median line. Into the loops formed by the suture he would introduce a piece of quill or bougie, and by drawing the stitches tight a perfect adaptation and slight eversion of the edges will be produced. Four or five superficial sutures will serve to bring the edges nicely together.

The deep sutures, which are the most important of all, he does not disturb under forty-five to forty-eight hours, though it is rarely necessary to leave them longer. The superficial sutures, however, he leaves for five or six days; almost invariably a perfect union results. Cases have come to him in which failures have resulted from making the denuded surfaces too narrow, thus leading to the formation of recto-vaginal fistula, and in other instances leaving a septum too thin to withstand the forces likely to be brought to bear on this part. It is customary with him to leave a catheter in the bladder for four or five days in order to prevent any contact of urine with the cut surfaces, and to keep the patient on her back until the third day, when she can be laid on either side for two or three days, and then turned on to the back again. He also approved the administration, after the operation, of opium in doses of one grain every four or six hours to produce rest, and to keep the bowels confined. The latter condition is to be maintained, if possible, for ten or twelve days.

Dr. Benjamin Howard then read to the Society a paper on "The Cure of Urinary Perineal Fistulæ with Stricture, without the ordinary Cutting Operation," which mainly consisted of the report of a case in which this complication of stricture was speedily cured by causing a catheter to be retained in the urethra, so that no urine was permitted to pass through the fistulous canals.

Dr. Stein hesitated in responding to the invitation of the President, since he could add very little to the statements made by Dr. Howard, and all he should say would be in confirmation of them. He observed, however, that several questions of importance were involved in the treatment of stricture, and not the least was that of the location of the disease and its character as dependent upon location in the fibrous or the sub-mucous connective tissue; and assumed that strictures seated in the fibrous tissue of the corpus spongiosum do not yield by any means of treatment so readily as when they are confined to the sub-mucous connective tissue. He mentioned in confirmation of this a case in which internal urethrotomy and gradual dilatation were powerless to effect a cure, owing to the disposition of the tissues to contract, and in which external urethrotomy had ultimately to be made.

Dr. Stein also related a case showing the effect of extra-urethral abscess in producing stricture.

Dr. Wm. T. White also related a case which he observed a year ago, and which, he thought, seemed to prove what Dr. Howard said with regard to the disposition of urinary fistulæ to close when relieved of the passage of urine. The patient in question had congenital phymosis, with a prepuce adherent to the glans. An operation was made for the cure of the phymosis, and a number eight sound being introduced, a stricture was discovered at a distance of three inches, and in further examination with a filiform bougie was found to be an inch in length. The day was dark, and the patient behaved badly under chloroform, and considerable difficulty attended the examination. Twelve days after the exploration of the stricture, one and a half inches of the calibre of the urethra corresponding to the seat of the stricture sloughed out, and two-thirds of his urine passed through this fistulous opening in the perineum. Subsequently the opening was closed by taking flaps of skin from the scrotum, and during the process of healing (about two weeks) a catheter was retained in the bladder. The patient has since had no trouble in passing his urine. Dr. White had not been able to discover any cause for the stricture, the trouble in passing urine, like the phymosis, having always existed within the patient's recollection.

The President announced that Dr. J. C. Peters would read the next paper to the Society on the subject of the last revision of the Pharmacopœia, and stated that members of the College of Pharmacy were expected to be present, and take part in the discussion of the paper. He further called attention to the approaching meeting of the State Medical Society, and urged the delegates from this Society to be present promptly.

The Society then adjourned.

Correspondence.

PERCY'S ALKALOID HYPOPHOSPHITE.

AN ANSWER TO DR. E. PEUGNET.

To the Editor of the Medical Record.

Sir—In the Medical Record for March 15th is an article by Dr. E. Peugnet on the above chemical preparation. The Doctor styles it *so-called*, and cautions me that I must not nullify my physiological chemistry "by adopting either preconceived ideas or an unsupportable hypothesis."

Dr. Peugnet again says, "Dr. Percy, in his Prize Essay, has given us an almost complete chemical history of Phosphorus down to the present time; but we regret that he did not enter more fully into its toxicology." I regret to say that Dr. Peugnet has overrated my "chemical history," for I have, in truth, given but a very limited chemical history of such an important organismal element. But I have endeavored to give, and I think I have given, a more complete and thorough insight into its physiological distribution throughout the system; the ubiquity of its presence in some one or other of its chemical forms; the peculiarities of the chemical conditions in which

it exists in different organs; and the derangements which an organ may suffer by a mere chemical change of this important element. In short, I supposed that I had given but little of the chemistry, but that I had entered very fully into the animal and vegetable physiology of the element.

In every fully reported "Case" in my Essay the toxicological appearances were fully observed, and there are no cases that I have reported in which I have not fully pointed out "the morbid and deleterious effects of excessive and inordinate doses"* of phosphorus and its preparations. Dr. Peugnet evidently means *antidotal effects*, instead of "toxicology;" but, if so, he has not done me justice, for I have in numerous cases administered and thoroughly tried all the asserted antidotes and found their worthlessness, and have, in their place, pointed out a new and reliable antidote—oxygen. Dr. Peugnet seems to agree with most of the reviewers who have read my Essay, for he says, "The essentially original part of the Essay is that which relates to his so-called hypophosphite." I feel that they, and he too, will do me more justice if they will re-read my Essay.

It always seemed to me that it was necessary, before we tried any therapeutical experiments with a substance, that we should understand thoroughly what the substance was, and what were its chemical reactions: whether it was unlike all the known components of the system, or whether it was similar to some existing element therein. In the first 39 pages of my "Prize Essay," I have given a large number of analyses proving the presence of peculiarly varied and mobile combinations of phosphorus in all the living tissues of man and animals. Several years were spent by me in experimenting in like manner upon vegetables, and many analyses are given that are so new that I am not aware of similar labors, or results in any way approximating them; and I have in these numerous instances shown (in Dr. Peugnet's own words) that the vegetable as well as the animal "organism is a vast and complete chemical laboratory," self-appropriating and elaborating, not only the kind, but the quality of the organismal element it stands in need of.

I do not know where in chemical writings there are more chemical errors than in his paragraph commencing "Basing himself," et seq.

He tells us that lecithine is a "*neutral* phosphor*etted* fatty matter," and in the same sentence that it is "an *acid* phosph*ate;*" that it "is composed of nervine in combination with oleic *acid*, margaric *acid*, phosphoglyceric acid."

I believe in my Essay that I have stated, from actual observations and many experiments, that the "oleo-acide-phosphoric" of Fromy is a hypophosphite, and not a phosphate, and answers to all the tests of a hypophosphite until chemical "tortion" converts it into a phosphate. As I understand this sentence, Dr. Peugnet makes this assertion simply as all others have made it before him, and not that he has disproved my observations by any analyses of his own.

Mr. Spangenberg prepares according to my formula some of my alkaloid hypophosphite, and Dr. Peugnet, like myself, tried it therapeutically in some cases of nervous debility, and found it of very great value, producing beneficial effects that other medicines had failed to do. The Doctor then tests it chemically by macerating it in water, and by the several well-known chemical reactions he proves that it contains hypophosphorous acid ($3HO+PO$), and not a trace of phosphoric acid. His chemistry in this well-known test is quite correct. He then states, "it is therefore evident that this preparation is *not* an alkaloid, but that it is anhydrous hypophosphorous acid" (PO).

It is a well-known chemical fact that anhydrous hypophosphorous acid (PO) has no separate existence, and all the celebrated chemists, Graham included, failed to produce it. Hypophosphorous acid exists only in combination with water, two equivalents being necessary for its existence; the third equivalent may be exchanged for some base, but the two equivalents of water enter even into all its salts (MO, 2HO, PO). Rob it of either of these two equivalents of water and the acid is destroyed.

I endeavored by many means to form a hypophosphite without the combining equivalents of water, and succeeded at last in making it combine with other elements than water. I found in the brain a hypophosphite in combination with fatty matter without any combining water, and by numerous experiments I made the same substance. I have succeeded in finding a new base and a new combining element, for hypophosphorous acid; but this substance is not, as Dr. Peugnet asserts, *anhydrous* hypophosphorous acid (PO), but that acid in combination with two equivalents of fatty matter, and the other equivalent may be either fatty matter or some base, as a nitrogenous compound or an alkali (as for example KO, 2?, PO, using the arbitrary formula ?, to express the fatty body). Here at least is a chemical discovery, but not one at variance with the laws of nature.

But Dr. Peugnet, in his analysis, takes my alkaloid and subjects it to the decomposing agency of water, a substance for which it has the greatest affinity, for like all other chemicals it is decomposed by a stronger affinity, and enters into new combinations. I have shown, on Page 15 of my Essay, that its affinity for water is so great that it robs the water of combination even from sulphuric (HO, SO_3) and hydrochloric acids. In this analysis the hypophosphite has a stronger affinity for water than for the fatty and other bodies, and therefore the oleo-hypophosphite is decomposed.

And so on analyses the Doctor finds hypophosphorous acid (HO, 2HO, PO), and therefore concludes that I have formed simply PO without other combining elements. He does not examine the fluid for any other substance, and simply states that by the distillation of the remaining fatty matters no pure phosphorus was eliminated. There should have been, for there were phosphates still remaining in the beef extract.

The Doctor's analysis, after digesting the fluid with animal charcoal, is certainly incorrect, and he will prove it so if he tries it again; for he will find both superphosphate of lime and hypophosphite of lime: he says he obtained only hypophosphorous acid.

I do not think I need a better analysis than this of Dr. Peugnet's to prove that I am perfectly correct.

In my formula I dissolve phosphorus in a fatty substance, and by the direct action of oxygen convert it into hypophosphorous acid (PO), that at the moment of its generation takes to itself three equivalents of glycerine, and forms an oleo-hypophosphorous acid. Dr. Peugnet proves the correctness of this by finding (when the substance is put into water) hypophosphorous acid (HO, 2HO, PO) that there was no phosphorus left, and no phosphoric acid present. The process is the same without the beef extract, and the analysis would have the same result, for if either of the combining equivalents is changed, the whole is converted into another substance. He simply decomposed my oleo-hypophosphite into hydrated hypophosphite; had he used a greater heat he would have converted it into a phosphate. He proves that after

* Webster.

his decomposing agent, water, was added, there was nothing present but hydrated hypophosphorous acid; it could not exist as PO, that is, hypophosphorous acid, without any combined element, and therefore it combined with the oil.

In another paragraph, in which the Doctor speaks of a "liquid preparation similar to the first case he made with lard oil," he is reasoning *à priori*, and upon an "unsupportable hypothesis," for he disproves every word of his reasonings by his own previous analysis, in which he finds hypophosphorous acid (HO, 2HO, PO); he needs no hypothesis to argue out what possibly might be present, or to imagine certain decompositions; he has his own facts to prove the presence of hypophosphorous acid, and the absence of any other formula. He proves what I claim—a new chemical discovery.

Throughout the whole argument Dr. Peugnet tells us he found hypophosphorous acid, that is, a lesser oxide of phosphorus; at his conclusion he calls it a hyperoxide, that is, a greater oxide, a "so-called" phosphate.

I feel thankful to Dr. Peugnet for his honest, earnest, and labored criticism. I may be full of errors in my "hypothesis." If I am, I hope to elicit truth, and if I can elucidate any new facts I shall benefit the profession and necessarily, through it, the public.

I have discovered another and an easier means of making an oleo-hypophosphite, which, instead of tasting disagreeably, rather detracts from the oily taste of any oil in which it may be combined; it gives to the oil a rather pleasant sub-acid taste. When my investigations are more complete I will publish them to the profession.

I suggested in my Essay that I was at work endeavoring to prepare an organismal hypophosphite of a better formula than there presented, one such as exists in living animal and vegetable tissues. I have, I think, prepared from the germ of the wheat, from the fine inner bran, and from the brains of fish, a substance containing all that is contained in the alkaloid hypophosphite, and, in addition, phosphites, phosphates, and free hypophosphorous acid.

Unfortunately, the alkaloid I recommended in my essay is disagreeable to the taste, and some persons do not like to take it on account of this taste; the Vitalized phosphates I have now prepared have not that objection, as they are quite pleasant to the taste.

These Vitalized hypophosphites may be obtained for the use of the profession at Caswell & Hazzard's, Fifth Avenue Hotel, and corner 6th avenue and 39th street.

SAMUEL R. PERCY, M.D.

47 West 38th street, New York, March 31st, 1873.

ARMY NEWS.

Official List of Changes of Stations and duties of Officers of the Medical Department, United States Army, from March 19, 1873, to April 4, 1873.

McKEE, J. C., Surgeon.—Granted leave of absence for six months on Surgeon's certificate of disability, with permission to go beyond sea. S. O. 57, A. G. O., March 19, 1873.

BILL, J. H., Surgeon.—Assigned to temporary duty at David's Island, N. Y. H. S. O. 55, Department of the East, March 22, 1873.

ALDEN, C. H., Surgeon.—Granted leave of absence for four months, with permission to go beyond sea. S. O. 56, A. G. O., March 18, 1873.

TILTON, H. R., Assistant Surgeon.—Assigned to duty as Post Surgeon at Fort Wadsworth, N. Y. H. S. O. 55, c. s., Department of the East.

COUES, ELLIOTT, Assistant Surgeon.—Assigned to duty, as Medical Officer and Naturalist, with the expedition for the survey of the Northern Boundary. S. O. 68, A. G. O., March 31, 1873.

STYER, CHARLES, Assistant Surgeon.—Leave of absence extended to include May 10, 1873. S. O. 66, A. G. O., March 28, 1873.

EWEN, C., Assistant Surgeon.—Assigned to duty at Little Rock, Ark. S. O. 47, Department of the Gulf, March 24, 1873.

WINNE, CHARLES K., Assistant Surgeon.—Leave of absence granted for six months from April 15, 1873, and his resignation accepted by the President, to take effect October 15, 1873. S. O. 55, A. G. O., March 15, 1873.

Medical Items and News.

MEDICAL SOCIETY OF COUNTY OF HUDSON, N. J.—At the regular meeting of the District Medical Society for the County of Hudson, N. J., held at the Court House April 1st, 1873, the following officers were elected to fill vacancies: *President*, Dr. D. B. Carpenter; *Vice-President*, Dr. S. R. Forman; *Treasurer*, Dr. Everett. Dr. H. M. Eddy was elected Reporter to the State Medical Society. At the regular meeting in March the following members were elected delegates to the State society: At large, Drs. Lutkins, Reeve, and Carpenter; Representatives, Drs. Vondy, Hunt, Buffett, Noble, and Craig.

MEDICAL LIBRARY AND JOURNAL ASSOCIATION OF NEW YORK.—At the stated reunion of this association, held March 28th, 1873, Dr. John C. Peters, President, in the chair, Dr. Beverley Robinson, graduate of the School of Medicine, Paris, read an important paper on "Cardiac Thrombosis in Diphtheria," in which the following conclusions were brought out:—

1st. Cardiac thrombosis is a tolerably frequent complication of diphtheria.

2d. Fibrinous, elastic coagula, twisted between the valves, or which adhere intimately to the walls of the heart, form before death.

3d. These coagula are often produced, apart from the agony, in children who are far from having reached extreme feebleness; for he has recognized them several times when the child appeared convalescent,—when everything betokened an early recovery.

4th. They cause very grave symptoms, which may give rise to suspicions of their presence.

5th. The diagnosis of these concretions is important, from the double standpoint of the prognosis and treatment; since, on the one hand, their existence in the course of diphtheria renders the fatal termination almost sure; and, on the other hand, it makes the operation of tracheotomy useless, at least in some cases.

6th. The polypiform clots are frequently the proximate cause of the very grave state in which the patient is found, and not the result of this state itself.

7th. Death may occur in a sudden manner immediately after the detection of the thrombosis, or else after a state of anxiety or anguish, more or less protracted.

Drs. Leaming, Putnam, Jacobi, and the President made remarks on the paper.

ERRATUM.—In our issue of April 1st, it was announced that Prof. William T. Frink would read a paper at the stated meeting of the N. Y. Academy of Medicine, April 17th, on "The Etiology and Indications for the Treatment of Irregular Uterine Action during Labor." The name of the speaker should read Prof. William T. Lusk.

GIFT TO PROF. AGASSIZ'S MUSEUM.—Mr. John Anderson, of New York, the well-known tobacconist, has presented Prof. Agassiz with an island in Buzzard's Bay, upon which to establish his proposed Summer School and Museum of Comparative Zoology, also the sum of $50,000 towards the permanent fund for the Museum. The Legislature of Massachusetts also proposes to appropriate $50,000 to Prof. Agassiz's project.

CORNWALL.—Mr. H. B. Cornwall, of the New York School of Mines, has accepted the assistant professorship of Analytical Chemistry and Mineralogy in the School of Science of Princeton College, N. J.

THE NEW YORK SOCIETY FOR THE RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—At the 50th annual meeting of the above named Society, the following named gentlemen were elected officers for 1873:—

President, Dr. John O. Stone; *Vice-Presidents*, Dr. J. R. Van Kleek, Dr. L. T. Hubbard, and Dr. John G. Adams; *Treasurer*, Dr. J. W. G. Clements; *Managers to serve three years*, Dr. Jared Linsly, Dr. A. Underhill, Dr. E. L. Beadle, Dr. J. O. Smith, Dr. Gouverneur M. Smith, Dr. Joel Foster, Dr. Thomas F. Cock.

At a subsequent meeting of the Board of Managers, Dr. Gouverneur M. Smith was elected Secretary of the Society, and Drs. William C. Roberts, James H. Anderson, and Robert Watts elected managers to fill vacancies in the Board occasioned by the deaths of Drs. H. D. Bulkley and C. Henschel, and by the election of Dr. Hubbard to the vice-presidency.

The Society has funds invested amounting to about ninety thousand dollars, and at this date extends aid to six widows and three children of its deceased members.

A CITY OF THE DEAD.—During the year 1872, 6,573 persons were interred in Greenwood Cemetery, Brooklyn, N. Y., making a total of 161,376 inhabitants of the necropolis.

A NEW HOSPITAL AT BALTIMORE, MD.—J. S. Hopkins, the well-known millionaire of Baltimore, Md., recently deeded to trustees thirteen acres of land, bounded by Wolfe, Monument, Broadway, and Jefferson streets, for the erection of a hospital for the relief of indigent sick and orphans. At a late meeting of the Board they were notified by Mr. Hopkins that he had further dedicated $2,000,000 worth of property for the support and maintenance of the hospital. The hospital buildings will be on a magnificent scale.

MEDICAL COMMENCEMENTS.—The commencement of the Jefferson Medical College, Philadelphia, Pa., took place March 12, 1873, at the Academy of Music; 149 graduates received diplomas.

The Medical Department of the University of Pennsylvania held its annual commencement at the Academy of Music, Philadelphia, March 13, 1873. Diplomas were given to 99 graduates.

The first commencement of the College of Physicians and Surgeons, Baltimore, Md., was held at the Masonic Temple, February 18, 1873. Diplomas were presented to 18 graduates.

The 52d commencement of the Medical College of Ohio was held in Pike's Opera House, Cincinnati, March 1, 1873; the degree of M.D. was conferred on 94 graduates.

The commencement exercises of Rush Medical College, Chicago, Ill., took place February 19, 1873; 62 candidates received diplomas.

At the recent commencement of the Missouri Medical College, St. Louis, 21 graduates received the degree of M.D.

ELECTRO-THERAPEUTICS.—A new monthly journal especially devoted to electro-therapeutics, under the name of *Il Galvani*, is to be started in Urbino, in Italy.

COD-LIVER OIL.—The editor of the *Nashville Journal of Medicine and Surgery*, in reviewing the history of that periodical, which was commenced January 1, 1851, alludes to an original article in the first number, entitled, "Six Cases of Phthisis Pulmonalis Treated by Cod-Liver Oil," by D. W. Yandell, M.D., of Louisville, for the purpose of recalling the fact that these were "the first original cases upon tuberculosis treated by cod-liver oil published by an American physician;" "the first published in the English language having been by Dr. C. J. B. Williams, in 1849, consisting of notes of 234 cases."

MEDICAL SOCIETY OF THE STATE OF NEW YORK.—Since the organization of this Society in 1806, 145 medical men have been elected *Honorary Members*; of these 119 were non-residents of the State; 71 only are now living. 416 *Permanent Members* have been elected from the years 1813 to 1871, inclusive; of these, 306 are now living. The Regents of the University have conferred the honorary degree of Doctor of Medicine upon 115 gentlemen on the recommendation of the State Medical Society; of these, 49 have died. Eligible for election as permanent members, 134. Eligible for election as honorary members, 14. Of the 48 ex-presidents, 30 have died. 54 county societies are represented in the parent society, representing 2,432 members. The average attendance at the annual meetings held in Albany in February of each year, is about 350.

BRAIN DISEASES IN ENGLAND.—According to Dr. Charles Elam, of London, during the last thirty years, while the English population has increased thirty per cent., the mortality due to diseases of the brain has multiplied nearly four-fold. This he attributes to the fact that "the great development of railway and telegraphic communication has resulted in an enormous increase of business transactions, entailing a vast augmentation of the cares, worries, and anxieties of life. The brain, receptive of all impressions, and originating all volitional impulses, has a double load to bear in the economy, etc."

A NEW MEDICAL STUDENTS' JOURNAL.—A new periodical, called "*The Students' Journal and Hospital Gazette*," has been issued with the opening of the new year in London, England. It will appear fortnightly.

A PLEA FOR THE TRACTOR.—Dr. Wm. Goodell, of Philadelphia (*American Practitioner*, Jan. 1873), shows that the action of the vectis is mainly that of a tractor, and the aim of the operator should be to use the instrument as a hook, rather than as a lever.

SUICIDES IN NEW YORK CITY.—During the year 1872, 140 persons committed suicide in this city. In 1870 there were 108 suicides; in 1871 there were 112. Of the 140 cases, only 36, or about 25 per cent., were

natives of the United States. Germany takes the lead, furnishing 56 cases. Next to the Germans in the record of foreign suicides come the Irish, who furnish 19 cases. Of the whole, one-half of them were between 20 and 40 years of age, and more than one-third were between 30 and 40; 110 were males and 30 females; 35 of the 140 shot, and 48 poisoned themselves; 35 men and 13 women poisoned themselves, and Paris green was chosen in 25 cases out of 48.

STRICTURE OF THE RECTUM.—Dr. White, of Bath, in his "Observations on Stricture of the Rectum," 1820, was the first English surgeon to write a work on stricture of the rectum. He made no mention of the venereal poison as a cause of stricture. This is also the case with Mayo, of London, 1833, and Frederick Tatham, 1833, and even Mr. Syme, 1839. Dr. Erskine Mason, in his paper on "Venereal Stricture of the Rectum" (*Am. Jour. Med. Sciences*, Jan. 1873), says the French were the first to have spoken on this subject. Richerand, in 1815, spoke of *condylomas internes* of the rectum. After somewhat extensive experience with this disease, Dr. Mason accepts *in toto* the views first advocated by M. Gosselin, in the *Archives Générales de Médicine*, 1854, and adds his quota to the proof that these *so-called syphilitic strictures* are in no wise due to syphilis, but arise from the local and non-infecting chancroid.

THE TEA QUESTION.—In the United Kingdom alone, in 1871, 123,401,889 pounds of tea were consumed.

In a paper by Dr. Adam Smith, read before the London Society of Arts, the use of tea was recommended in the following cases:—After a full meal, when the system is oppressed; for the corpulent and the old; for hot climates, and especially for those who, living there, eat freely, or drink milk or alcohol; in cases of suspended animation; for soldiers who, in time of peace, take too much food in relation to the waste proceeding in the body; for soldiers and others marching in hot climates, for then, by promoting evaporation and cooling the body, it prevents in a degree the effects of too much food, as of too great heat.

SLOW POISONING.—The secular and medical journals are constantly reciting cases of slow-poisoning from *green wall paper*, which is now so much in vogue. Mr. Joseph Hall, State Chemist, at Hartford, Ct., estimates that every square-foot of this innocent-looking paper contains an amount of poison equivalent to five grains of arsenious acid, or double the fatal dose for an adult person.

FŒTICIDE.—At the request of many of his former pupils, Dr. Hugh L. Hodge, of Philadelphia, has consented to the republication of his Introductory Lectures of 1839 and 1854, on "Fœticide or Criminal Abortion," being the opening of the course on obstetrics and diseases of women and children, University of Pennsylvania.

It has come to hand neatly gotten up in hand-book form, comprising 55 pages, and is published by Lindsay & Blakiston.

THE TEETH.—A series of short articles on "The Teeth: Notes on their Pathology," which originally appeared in the *British Journal of Dental Science*, written by Oakley Coles, L.D.S.R.C.S., are reproduced in monograph form, with well-defined illustrations from Brücke. J. & A. Churchill, of London, are the publishers. The author remarks "that they are now offered to the profession, rather as suggestive of fresh lines of thought, than as a finished contribution to dental literature."

THE WOMEN OF HUMBOLDT COUNTY OF CALIFORNIA.—Dr. Geo. L. Fitch, Little Lake, Cal. (*Pacific Med. and Surg. Jour.*, Jan. 1873) doubts if there is a real healthy woman within the limits of this county. The constant fog and cold winds exert a peculiarly depressing influence on women, and as a consequence their menstrual function is nearly always deranged, extremes in this respect being the rule. He speaks of a case of flooding for several hours in a child aged 9 years, whose pelvis was large. There was no hymen. She had not been tampered with. Seven months from the first attack the hæmorrhage from the vagina and uterus returned again, but not so badly as before. Cold cloths and gallic acid promptly checked the flow.

FREE PARKS AS SANITARIUMS.—A reprint from the *Northwestern Medical and Surgical Journal* gives Dr. J. M. Toner's practical article on "Free Parks and Camping-Grounds, or Sanitariums," for the sick and debilitated children of large cities during the summer months. Dr. H. C. Hand's chapter on "Infant Mortality" is appended.

MEDICAL RESPONSIBILITY AND MALPRACTICE.—This is the title of an excellent address delivered February 7th, 1872, by William C. Wey, M.D., late President of the Medical Society of the State of New York, at the sixty-sixth annual meeting. This, with the opening address delivered February 6th, 1872, is published in pamphlet form.

OVARIOTOMISTS.—J. B. Lippincott & Co., of Philadelphia, publish the paper prepared for the last meeting of the American Medical Association, by S. Fitch, M.D. Edin., of Portland, Maine, giving the peculiarities in the operations of the three following Ovariotomists: T. Spencer Wells, of London; W. L. Atlee, of Philadelphia; and Thomas Keith, of Edinburgh.

The important points advanced in the pamphlet are elaborately discussed in the late works of Drs. Peaslee and Atlee, to which the profession have so recently been directed.

DIPLOPIA FOLLOWING THE USE OF CHLORAL.—A case of this character, following the administration of this remedy, is reported by William R. Mandeville, M.D., A. A. Surg., Post Hospital, U. S. A., Aberdeen, Miss., in the October number of the *American Journal Medical Sciences*. A male, suffering from a carious dens sapientiæ, took ninety grains, in three doses of thirty grains each, within two grains. The next day the patient complained of seeing everything double, and of specks continually floating before his eyes—muscæ volitantes. This condition of his eyes lasted three days.

GOITRE IN GEORGIA.—According to the *Georgia Medical Companion*, there is a neighborhood on the head waters of Lott's Creek, Scarboro, Georgia, containing about fifty families, and spread over a territory of about five to seven miles, the female portion of which seems to be predisposed to this disease. There is rarely a female that has arrived at puberty that is not afflicted with it. It has been so with almost all the women raised there. There never was a male known to have it in that settlement. The disease yields readily to the iodine treatment. The soil is sandy, growth principally pine, interspersed with broad leaf jack. The drinking-water is obtained from wells, the average depth of which is about twenty feet. The locality is noted for its extreme healthfulness in other respects.

Original Lectures.

ON BRIGHT'S DISEASE.

By ALFRED L. LOOMIS, M.D.,

PROF. PRACT. MED. UNIV. MED. COLLEGE, N. Y.

(Phonographically Reported for the MEDICAL RECORD.)

LECTURE I.

GENTLEMEN:—At my last lecture I described to you the pathological lesions of the different forms of Bright's disease of the kidney. This evening I shall speak to you of the symptoms which mark the developments of these anatomical changes, and I shall consider them in connection with the different stages of the disease which I described at my last lecture. Before entering in detail upon the history of these symptoms, I wish to say a word in regard to urea, the presence of which in the circulation is supposed to have very much to do with the production of very many, if not all the phenomena of the disease. I am aware that this statement requires some qualification, for there have been many theories advanced in relation to the poisonous element in Bright's disease. Some have maintained that this condition occurs independent of the urea, that the urea underwent decomposition, that ammonia was evolved, and that the ammonia was the poisonous element. Others that it is due to structural changes in the brain similar to those in the retina in neuro retinitis.

Others, again, have supposed that the changes in the nervous centres, particularly of the brain, which gave rise to the nervous phenomena of the disease, were due to œdema of the brain tissue. After carefully reviewing all the theories, and going over the experiments made relating to them, I must say that the theory which assumes that urea is the poisonous element which produces the condition known as uræmia is the most reasonable, and, at the same time, is better sustained by facts and experiments than any other. In health only a trace of urea is found in the blood. It is not produced by any special organ or tissue of the body, but is undoubtedly the united product of all the nitrogenous effete material of the body.

In health we eliminate about 500 grs. every twenty-four hours, and it is the office of the kidney to eliminate this urea. Now, whenever the function of the kidneys is interfered with or arrested, the urea accumulates in the blood; acting, it seems to me, as a direct irritating poison, interfering more or less with all the functions of organic life.

If a person takes a large dose of urea, as it were, at one draught, a violent and overwhelming influence is exerted upon the nervous system, the urea showing its effects by convulsions, coma, and death. If taken in small doses, the drinking carried on for a long time, its first effect is to interfere with digestion; secondly, it effects changes in nutrition, and all the elements of the blood become so changed, that no one of the functions of the body is carried on in its normal state. This seems to me to be the correct explanation of the nervous phenomena connected with the history of Bright's disease. First, that there is poisoning of the system by urea; second, by arterial tension and cerebral œdema. In detailing the symptoms of this disease, I shall speak first of those which mark the different stages of inflammatory form, or that form which I told you Virchow described as parenchymatous nephritis.

It has its seat, and all the primary changes are found in the tubules of the kidney. In connection with this form, the first thing that the patient notices ordinarily is slight œdema of the face. If he is in a weak condition from any other disease, at the time of the occurrence of the nephritis, you will find œdema commencing in other parts of the body, perhaps of the feet first, but, as a rule, the œdema commences in the face.

With the occurrence of the œdema there is a restlessness about the patient, which he cannot account for; he has headache, usually constant, which seems to increase in severity from hour to hour. If the patient is closely questioned, he will state that recently he has noticed some change in his urine; that it has been scanty, high-colored, and perhaps there has been some pain in the back, and along the loins. He has had frequent desire to pass urine. He may also complain of dyspeptic symptoms, some nausea, perhaps vomiting, which sometimes is a very troublesome symptom. Sometimes this symptom of vomiting is so troublesome, that the physician will direct his attention to the stomach as being the seat of all the trouble, and treat the patient for some gastric disease. There is more or less of febrile movement, as indicated by the acceleration of the pulse and elevation in temperature. The skin, as a rule, is more dry than natural; occasionally it is moist, but when it is, the perspiration has a peculiar urinous odor. This is a description of the milder form of the first stage of parenchymatous nephritis.

In a favorable case, a case of the best caste, after the patient has reached the condition described, he begins to improve; the urine is increased in quantity, the œdema gradually disappears, the head-ache moderates, the dyspeptic symptoms abate, and in the course of two or three weeks the patient has entirely recovered. In a large proportion of cases, however, no such favorable issue is to be expected. Instead of improving, the patient gets worse from day to day; the œdema is present not only in the feet and face, but extends over the entire body. All the cellular tissue of the body becomes œdematous externally and internally. Internally, the lungs become œdematous and we have dyspnœa. Dyspnœa however, in this connection, is not always dependent upon an œdematous condition of the lung, for there is such a thing as uræmic dyspnœa independent of any change in the lung tissue, but when the general anasarca just described is present, you will recognize that probably there is œdema of the lungs. The pulmonary œdema may also sometimes be accompanied with more or less pulmonary congestion, giving a watery expectoration, which will sometimes be streaked with blood. If the disease progresses, the anasarca will gradually increase, until the patient becomes perfectly water-logged. From this the still graver symptoms may occur indicative of approaching convulsions; convulsions may occur, coma come on, and death follow; death may also occur from some acute secondary inflammation. This is the history of many cases of the inflammatory form of the disease.

There is another class of cases, and quite a large one too, which do not recover or die, but become chronic. They go on, become water-logged more or less, have more or less œdema of the lungs and dyspnœa, and present a very pallid appearance. The pallor is peculiar; not like the clear pallor of phthisis, nor like the dingy pallor of cancer; but a peculiar pallor, not easily described, but which is peculiar to Bright's disease, and is easily recognized after it is once seen.

In these cases the œdema may gradually disappear, the appetite slowly return; the patient seems to be convalescing, and even gets into a comfortable degree of

health; he has passed through the first stage, through the second and into the third stage, or stage of atrophy. He now is in the stage of permanently enfeebled health; the œdema, however, never entirely disappears, and this is the peculiarity of this form of Bright's disease, even in the stage of atrophy. The patient, as a rule, does not get entirely rid of the œdema. It can always be detected by pressing firmly along the course of the tibia, or behind the internal malleolus, and is indicated by the little pit which can be made, showing that there is œdema of the cellular tissue. Another class of cases, in which the acute inflammatory form of Bright's disease is present, present symptoms more violent than either of the classes to which reference has been made. In this class of cases the patient is seized with a chill, has pain in the back and along the ureters with retraction of the testicles. There is delirium, great disturbance of the nervous system, and the patient presents an array of symptoms which are in every way urgent. The patient may pass into coma and die within two or three days. This is the very acute form of tubular or parenchymatous nephritis. In the clinical history of the inflammatory form of Bright's disease, there are three classes of symptoms which are of special importance, to which I will now particularly invite your attention. These are: (1) Those connected with the urine; (2) Those connected with the dropsy, and (3) Those connected with the nervous system. These three classes of symptoms are present in all cases of parenchymatous nephritis or the inflammatory form of Bright's disease. First, of the urine: In reciting the clinical history, I told you it was high-colored, scanty at first, and sometimes it has a smoky appearance. If it is examined for its specific gravity, that will be found high, perhaps as high as 1030. If tested for albumen, perhaps $\frac{1}{3}$ or $\frac{3}{4}$ of the bulk of the specimen will coagulate. If the urine is acid, testing with heat will coagulate the albumen, but if the urine is alkaline acid must be added first, or heat will not coagulate the albumen.

It is important therefore, that the testing should be done with the heat first, and then the acid and heat. The next thing to be determined is whether casts are present or not. What kind of casts do we expect to find? In the acute stage, those tube casts will be found which are made up of the different elements which I described in my former lecture as marking the pathological changes which took place in the uriniferous tubes, viz.: granular epithelial casts. Casts of this character are found in no other form of Bright's disease; not in the amyloid kidney, nor in the cirrhotic kidney, unless you have a complication by the ingrafting of the inflammatory form upon them. Whenever granular epithelial casts are found in the urine, you may be sure that there has been a recent inflammatory change in the tubules. There may also be present fibrinous, exudative matter, and it may be poured out into the centre of the tubular cavity; but the casts formed of this material under such circumstances will be of small size, what are called the *small hyaline* casts. The term hyaline used to be improperly called waxy. The material of which the cast is composed is simply coagulated fibrine.

With these casts of small size, are sometimes found more or less of what are termed blood-casts, fibrinous matter with blood globules, and sometimes mixed with this material, epithelial cells of a distinctly granular character. The epithelial cells may be simply thrown off and found lying loose in the urine.

If, therefore, you find a patient who furnishes urine of high specific gravity, containing granular epithelial casts, small exudative casts, and some blood globules mixed with them, you may be certain that the patient is in the acute stage of parenchymatous nephritis. There is no question, if he gives active symptoms, headache, more or less œdema, &c., which have been mentioned, and his urine furnishes us with the characteristics which also have just been described. As the patient goes on from this acute stage and passes into the stage in which the fatty changes take place in the tubes, whether he is to recover or not, the urine becomes more abundant, not so highly colored, specific gravity becomes lower, &c.

The specific gravity never gets very low in any stage until we reach the stage of atrophy. The specific gravity however is somewhat lower in the fatty stage than in the acute stage, and the quantity of albumen is somewhat diminished. These may be regarded, perhaps, as very good signs, but before positive opinions are expressed upon this point, it is important to determine what kind of casts the urine now furnishes. If fatty epithelium, and fatty and granular casts are found, you may be sure that the patient has passed well into the second stage of the inflammatory form of the disease. He has now what you may call a fatty kidney, if you choose. If you find along with this hyaline material, fine granular casts, you may be sure that he has something beyond the fatty change, and that the molecular changes which precede and accompany the process of atrophy have commenced. You have no more of the granular epithelial casts in this fatty stage, but you have hyaline casts which are of large size, and they will contain oil globules, and epithelial cells in which there are oil globules.

As the patient goes on to the next step, or stage of atrophy, the urine is increased in quantity, it *may* be very abundant; the high color diminishes or disappears; the specific gravity becomes lower, as low as 1010, and it contains very much less albumen than before.

The major portion of the casts now found, are large hyaline and fine granular casts; but in these casts there may be oily material, occasional fat globules, and occasional epithelial cells.

The patient now may get into a very comfortable condition; general health poor, it is true; not up to the normal standard; perhaps may have a little œdema of the feet, but as long as he takes good care of himself, keeps in a warm climate, he will get along very well, and may go on for a long time. What is the danger in such a case? The patient is not going to die from the kidney disease already existing; he is taking small doses of urea, it is true, but it is not sufficient to interfere with his general health to any serious extent; but his danger is, that some of these tubules which are doing the work may become the seat of an *acute inflammation*, and he may have the first stage of the inflammatory form of the disease ingrafted upon this stage of atrophy. The œdema may suddenly increase; general anasarca immediately follow, the patient pass into convulsions, and die suddenly.

(The Professor then related a case illustrating the danger in question.) A patient in this stage of Bright's disease, whom, in view of the danger, he had sent South to remain during the winter months, finding himself as he fancied well, after a month's sojourn in a warm climate, returned. Upon the first night of his return he went on a little spree, during which he was exposed to cold, had a chill, and within twenty-four hours had complete suppression of urine, was seized with a convulsion, and died. If this patient had taken heed to the advice given him, he probably might have lived comfortably for a considerable length of time.

So much for the urine: you readily see the import-

ance of understanding how to examine it, and also of making frequent examinations. I may say also, that it is quite important to make a quantitative as well as a qualitative analysis. You can prognosticate much better if you know how much urea the patient is passing, for it may suddenly diminish in quantity, evidencing that some trouble is approaching, which cannot be recognized in any other way. There is one obstacle in this, however, as yet, for the healthy significance of these changes is not perhaps fully understood; *i. e.*, the determination of how much a person may fall in his daily quantity of urea and not be particularly endangered by it.

We next come to consider the dropsy.

This occurs early, and is one of the symptoms which is present all through the course of this form of Bright's disease. Why it occurs I am not certain. Perhaps it occurs from a number of causes, and several explanations have been given: First, it is said to occur on account of a sudden withdrawal of a large amount of albumen from the blood.

It also occurs to some extent from the failure of the kidneys to eliminate the watery portion of the blood in the form of urine. Sometimes we have sudden œdema taking place associated with an almost complete suppression of urine. Under these circumstances, undoubtedly the drawing off of the albumen has something to do with the œdema, but the shutting in of the watery eliminations of the body has much more. There is another cause which is spoken of, viz.: that the capillary force of the circulation becomes impaired, on account of the poisonous effect of the urea in the circulation.

We know that wherever the capillary circulation is slow, there we are most likely to find œdema. Perhaps all of these alleged causes may be sufficient to explain the occurrence of the dropsy, and we will proceed to speak more particularly of its clinical history.

In the last stage, or stage of atrophy, or when the patient has what is termed chronic Bright's disease, you have in addition to the causes mentioned for the dropsy, the anæmic condition of the patient. The repair of the blood is interfered with as well as the repair of the other tissues of the body, placing it in a favorable condition for the occurrence of dropsy. I think it may be set down that dropsy is a necessary symptom of the inflammatory form of Bright's disease. In the stage of atrophy it may not be very marked, but there is some œdema still remaining. In the early stages of the disease, however, it is a very marked and constant symptom. We next come to speak with regard to the nervous symptoms which occur in this form of Bright's disease. It seems that there is a retention in the circulation of some element which has a peculiar effect upon the nervous system. If you please you may say that it is due to the retention of all the elements of the urine, but it seems more reasonable to suppose that the urea is the substance which produces the irritation, by its peculiar effect upon the nervous centres. The theories on this point I have already referred to.

The first thing perhaps that will be noticed will be a more or less severe headache accompanied by restlessness. A severe headache in Bright's disease always means something, and must not be disregarded, for it is often the precursor of more dangerous symptoms. If permitted to go on, perhaps we may have convulsions after a little time, and this may be followed by coma. Or, if the poisoning goes on more gradually the patient may first get drowsy, and then you may be on the lookout for coma. We are not so apt to have convulsions under these circumstances as when the poisoning takes place rapidly. The changes in the nervous system depend upon the changes which take place primarily in the nutritive processes of the body from the circulation of the poisonous element urea, and I believe that the dropsy and other symptoms depend very much upon the same cause. By remembering these few simple rules of the clinical history of this disease, you will be able, almost always, to tell where your patient stands, what form of the disease he has by the history, although you may not see him until he has reached the stage of atrophy, and by his history you can determine pretty certainly, if the case at the commencement was one of parenchymatous nephritis. In this form of Bright's disease we may have many complications, and the complications may cover up the ordinary symptoms of the disease.

The first complication I mention is the hypertrophy of the heart. This will not be found in the first stage of this form of the disease, but it will be found after the patient has passed into the chronic stage of the disease; perhaps in connection with the fatty kidney, but especially in the stage of atrophy.

This cardiac hypertrophy has come to be with me a very strong element in making out a diagnosis with regard to the different stages of this form of Bright's disease. To illustrate: a patient is brought into the hospital having convulsions; it is important to determine whether it is his first attack or not. The urine is examined, and all the elements are present which indicate an acute stage of the inflammatory form; but he may have the acute inflammatory form ingrafted upon the chronic form of the disease. Now examine the heart, and if hypertrophy of the left ventricle is found, without valvular lesion, it is almost certain that the patient has chronic Bright's disease, and that he is now suffering from an acute nephritis ingrafted upon a chronic, for in the first stage and first attack there is no cardiac change.

It is always present in the chronic stage. It occurs in the same manner as hypertrophy in general does, from an increased amount of labor. Impurity of the blood, if you choose, interferes with readiness of the circulation through the capillaries, and then you have the paralyzing influence of the capillary circulation, which is exhibited by the disturbance of the relations between the normal constituents of the blood and the vessels, which interferes more or less with the circulation. The heart must carry on this circulation, and it is this increased work that constantly increases its labor, and causes the hypertrophy. It takes some time to accomplish this, and it is not generally until after months of suffering in this way that the heart begins to show it, by gradual increase in the size of the left ventricle. This is a very important complication, for it enables us to determine whether a given case is in the acute or chronic stage of the disease.

Another class of complications relate to the lungs and bronchial tubes. We may have pulmonary œdema, congestion and pneumonia, and occasionally capillary bronchitis, and occasionally simple bronchitis.

Pulmonary œdema and congestion comes in an acute stage, and the reasons I have given.

Pneumonia occurring in connection with Bright's disease is always of a severe type, and is a complication in which the patient is continually in danger.

The patient may do well, but there is constant danger lest pulmonary œdema makes its appearance at the same time in other portions of the lungs, or that the pneumonia itself will extend.

Pneumonia is more apt to occur in the acute stage or fatty stage than in the stage of atrophy.

Inflammation of serous membranes is another complication.

I believe that the serous membrane most commonly affected is the endocardium. I am aware that in making this statement I shall be contradicted by some, but I believe that there are many cases of chronic valvular lesion of the heart which had their origin in this complication occurring in connection with an acute attack of Bright's disease.

Pericarditis, pleurisy, and occasionally meningitis, may occur as complications. It is important to remember that one of the most dangerous complications of the acute form of Bright's disease is inflammation of the serous membranes.

Another complication which may occur is a subacute inflammation of the mucous membrane of the stomach. The mucous membrane undergoes structural changes and patients never entirely recover from these changes.

Amaurosis is another complication. This occurs in the very acute stage, not as the result of neuro-retinitis which occurs in the chronic form. The patient may be perfectly well up to a certain time, then for two or three days, he may notice some œdema, has some dyspnœa, becomes delirious, has high temperature, and becomes blind. Under such circumstances the loss of sight is not due to neuro-retinitis, but to some effect of the urea upon the nervous system which produces amaurosis. Some say that there is œdema of the retina, but this is not now generally accepted. It is certain, however, that it is not a neuro-retinitis, for there is no evidence by the ophthalmoscope which points satisfactorily in that direction.

These are the important complications which are liable to occur in this disease, viz.: first of the heart, second of the lungs and bronchial tubes, third inflammation of the serous membranes.

We come now to speak of the causes of the inflammatory form of Bright's disease, or parenchymatous nephritis. The most common cause is exposure to wet and cold, or in other words, changes in temperature. This is proved by the fact that it occurs most frequently in those who are exposed to sudden changes in temperature. Firemen are a class of men who are very liable to suffer from this disease. That class of men who are accustomed to go on a "spree" are favorite subjects. It is not the alcohol that does it, for there is no evidence that this is a producing cause, but the man who gets drunk is very liable to subject himself to exposures which chill him, and in this way he developes his Bright's disease. It is not the alcohol, but the exposure to wet and cold which is so frequently associated with it. Sometimes a very simple exposure is sufficient, like removing the clothing on a hot summer's day, and sitting down by a window or in an open draft of air, a sudden chill follows, pain in the back, &c. Usually the exposure must be more severe than this, but exposure to wet and cold may be set down as the most common cause.

The next most frequent cause is blood poisoning. Under that head may be included all those diseases which depend upon a blood poison for their cause, such as scarlet fever, typhus fever, pyæmia, rheumatism, and the whole class of diseases which are recognized as due to blood poisoning are fruitful causes of Bright's disease in its inflammatory form. It occurs in scarlet fever because the patient has a poison circulating in the blood; but not every case of scarlet fever has Bright's disease. In some seasons, perhaps, almost every case of scarlet fever will be followed by it, and in the next perhaps not a single case will occur, because of the difference in the type of the fever. In certain types and intensity of the poison, there is a very strong exciting influence to the development of tubular nephritis. Another cause exists in certain irritating substances which may be taken into the stomach, and have the power of increasing the urinary secretion.

Among these are cantharides and balsam of copaiba. More than one case has been caused by these agents, having been taken in too large doses, for the cure of a clap. Another cause is pregnancy. It is developed not infrequently in pregnancy, not because, as was once supposed, of the pressure of the uterus upon the abdominal blood-vessels, and preventing free return circulation, but because during pregnancy, there is a larger amount of excrementitious substances to be eliminated by the kidneys, and these are the substances which are very liable to irritate the kidneys and give rise to tubular inflammation.

This portion of our subject is a very interesting one, but we must stop the discussion at this point for the present. At our next lecture we shall pass to the consideration of the other forms of Bright's disease and endeavor to reach the treatment.

COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

SURGICAL CLINIQUE OF

PROF. WILLARD PARKER, M.D.

INFLAMMATION OF FIBROUS STRUCTURE ABOUT SHOULDER.

GENTLEMEN:—The first case presented to-day is this man, who is fifty years of age and a laborer. Some weeks ago he received a blow upon the outside of his shoulder. Since the injury he has been unable to use the limb, has been carrying the hand in a sling, and has suffered more or less pain up to the present time. As a result of this quiet, it will be seen that the shoulder generally has atrophied, the result simply of non-use of the parts. Injuries about the shoulder are often exceedingly troublesome, and sometimes exceedingly difficult in the way of diagnosis. In order to arrive at a correct diagnosis, it is necessary that we should proceed properly with the examination; and first, nothing is more necessary than a perfect familiarity with the anatomical construction of the joint, the bones and ligaments which enter into its composition. One element should particularly be kept in mind, and that is, the long head of the biceps, which penetrates the capsular ligament and runs across the joint lying in the bicipital groove of the humerus. In the next place, the limb should be placed in a proper position for examination. The most favorable position is with the forearm at a right angle with the arm, seizing the lower end of the humerus with one hand while the other rests over the top of the shoulder.

If rotation is now made, trouble about the ligamentous structures can at once be detected, for the ligaments are placed upon a stretch, and the patient will immediately complain of pain. The same motion also will develop crepitus if it is present; and if luxation has taken place, the head of the bone will be recognized as being out of its normal position.

By crowding the articular surfaces together, it is easily determined whether inflammation of the sy-

novial membrane is present or not, by the presence or absence of pain produced. It is also important to recollect that in the young subject, usually under fifteen years of age (yet it may occur as late as thirty years of age), diastasis takes place, and this circumstance must not be overlooked.

Again, we sometimes have an injury of the long head of the biceps as it passes through its groove, and a subsequent inflammation excited in the groove. This point can always be felt by placing the fingers upon the front part of the shoulder and slowly moving them forwards, until the bicipital groove is reached which contains the muscle. By pressing upon that and rotating the humerus upon its axis, the patient will at once complain of severe pain if an injury has been sustained at that point.

In this case there is no disturbance produced upon manipulation, except an uneasiness which is produced by rotating the bone upon its own axis, and there is tenderness along the bicipital groove. The diagnosis then is, that we have an inflammation involving the fibrous structures around the joint, namely, the capsular ligament, and particularly that portion through which the long head of the biceps passes.

Prognosis is good.

Treatment is rest and moderate counter-irritation, either by tr. iodine or small blister. Rest is a prime element in the treatment of these difficulties, yet keeping them too still will sometimes postpone their recovery. A poor man who is obliged to work will sometimes get well much quicker than a wealthy man who may not be obliged to labor or take exercise.

LUXATION OF ELBOW-JOINT—SEQUELÆ.

The second case which is presented to-day is this boy, six years of age, who had a luxation at the elbow-joint about two weeks ago, and from which he still continues to suffer. At the present time, motion about the joint is quite limited, and there is numbness and inability to move the forefinger and thumb of the corresponding hand.

Again, in order to place yourself in the most favorable position for arriving at a correct diagnosis, you must adopt a proper method of examination. With regard to the elbow-joint, the proper position is with the arm and forearm placed at right angles with each other, the palm of the hand looking directly into the patient's face. In this position the bones of the forearm are placed parallel to each other, the internal condyle, olecranon process and external condyle are placed in a direct line, and the head of the radius is easily accessible unless some fracture, dislocation, or diastasis has taken place. In this case, all these anatomical prominences are in their normal position; hence, by exclusion, we diagnosticate that this was a case of simple luxation.

In luxation of the ginglymoid joints, it is amazing to see how easily they are reduced, while with the orbicular articulations a good deal of force is usually required to get the bones into place again; but it is wonderful to notice how soon a man can work again after having sustained a luxation at an orbicular joint.

With the ginglymoid articulations, the fact with regard to recovery is far different. They are easily reduced, but slow of recovery, and just the opposite is experienced in the orbicular joints.

The reason is simply this: a large amount of white fibrous tissue enters into the structures about a ginglymoid articulation, and when inflammation is set up in this tissue, there is always a shortening taking place, and with this comes a slow recovery. The question of interest now is, what are you to do with such a case, for this is the exact condition of affairs here,—motion is limited and the mother alarmed? It is all embraced in three words, so far as passive motion or operative procedure is concerned, and these are, *let it alone.*

There is, seemingly, an almost irresistible tendency on the part of some to use cold water in the treatment of affections of the joints. There is an indefinite amount of harm done by using cold water in these affections, and yet cold water is sometimes invaluable in the treatment of the same kind of cases as this one. The rule in its use is, never to use cold water about a joint so long as there is the least trace of inflammatory action left there. The trouble is that it will excite a new inflammation, and make the matter worse than ever. In the great majority of cases, if it is not well known what to do in the treatment of a joint, if warm water is used, the treatment will be advantageous: warm water followed by hand friction as much as you like. When, however, all tenderness, all heat is gone, and nothing is needed but simply to tone up the parts, cold water may be very serviceable. All that is then necessary is a simple dash, followed by dry friction, until reaction is thoroughly established. This is one of a class of cases that constitutes the *pons asinorum* of the young medical man, and too much care cannot be exercised when such a case presents itself. Keep the rules in mind which I have just indicated, and you will be always right.

CONGENITAL HYDROCELE AND HERNIA.

The next case presented is one of *Hydrocele* and *Hernia*, in an infant six months old, both double and both congenital. The herniæ are inguinal. Congenital hydrocele is rare. I have seen but few cases before this one.

With regard to such cases of hernia, I will tell you to what point I have arrived in their treatment, but you must exercise your own judgment with regard to following the same plan. For a good many years I have done nothing for these cases of hernia in young children as far as the application of mechanical apparatus is concerned. Formerly I was in the habit of treating them, but I have found out that it is worse than naught, for all these mechanical appliances irritate the child immensely, and do no good. Keep the child in as good condition as possible, and leave the hernia alone. When the child gets so that it can run alone, then adjust a truss, and in a great many cases it will then produce a radical cure. But, it may be asked, are not these cases liable to become strangulated? Strangulation sometimes occurs, but it is rare. I was once called up at three o'clock in the morning to operate upon a child nine months old where hernia had become strangulated, and the operation permanently relieved the child, but very rarely do we have any trouble in this direction. If they must be treated, the only thing of service before the child is old enough to run alone is the use of the adhesive plaster. This can be used very satisfactorily in cases of umbilical hernia, and in those cases it may be employed as early as desirable. Make a roll of adhesive plaster a little conical, like the end of the finger, and of sufficient size to fill the opening in the abdominal wall. Reverse the hernia, place this roll of plaster immediately in the opening, and over this a strip of plaster reaching to the back bone upon either side. This to me is the most satisfactory method of treating umbilical hernia in children, and you can almost always succeed in curing those cases. With regard to the congenital hydrocele in this case, that should be let alone. If desirable to do something, a little warm water and salt

may be used night and morning. If it does not go away within a reasonable length of time, the scrotum may be pricked with a fine needle. The little holes thus made will give escape to the fluid, and give rise to sufficient inflammation to close up the cavity. If this does not answer, a little thread may be passed through the scrotum, which usually is quite sufficient. In the performance of both of these operations great care must be exercised that the intestine is not wounded. This case, gentlemen, which I now present, possesses a great amount of interest.

CONTUSION OF SCALP.

One week ago this lad fell and caused this contusion of the scalp, and we now have to deal with a soft tumor of moderate size, technically called hæmatoma. The more common sort of these tumors or contusions are those we have in connection with parturition, particularly in connection with primiparous cases. The labor may be somewhat tedious, and there may be quite a tumor at the presenting part during the whole time, and when the child is born, the friends and probably the doctor will be quite astonished at the presence of a tumor of considerable size upon the child's head. What is to be done with this class of troubles? Let them alone and they will always go away without any trouble. Sometimes, however, it will be necessary to do something to assuage the anxieties of the friends, but be careful that nothing is done which will produce harm. The tumor consists of blood, and the blood does not coagulate, which makes the case so much the more favorable. These extravasations sometimes are of enormous size, but I have never seen any occasion to meddle with them. I saw one case where the tumor had been opened, and in that case a slough took place afterwards, and a portion of bone came away. I believe it is advisable to let them alone, entirely alone. The sharp ring-like edge which is felt in these tumors at the point of injury is a little deceptive. It is nothing but the thickened edge of the soft parts, and is not bone. This is a practical point, for many a poor fellow has had his scalp cut into under the impression that it was a proper case for trephining.

SYPHILIS.

This man whom you now see is suffering from tertiary syphilis, and that is the cause of this diseased bone upon his skull.

In connection with this case I will say a few words concerning the treatment of syphilis.

It generally occurs in those men who are addicted to the use of alcoholic drinks. It may be in the gentleman who takes his bottle of wine at dinner, or his hot drink at bedtime; who lives pretty thoroughly upon his tobacco, and then the third partner in the firm comes in in the shape of syphilis. The trio consists of rum, tobacco and syphilis.

A vast number of our men who undertake to treat syphilis, treat the syphilis alone, never thinking to break off the rum and tobacco. The patient can never get well under such circumstances. With these three enemies in the system what chance can the doctor have to rout one while the other two stand ready to neutralize his efforts by carrying in sustenance for the third? I make it my rule, never to undertake the treatment of a case of syphilis unless the patient will give up his tobacco and rum, and coöperate unreservedly with me in the management of his case, and then it is comparatively an easy matter.

This is a practical point worth abiding by. Again, whenever a man has a constitutional disease, whether scrofula or syphilis or tuberculosis, or other disease, that man's system is *below par*; it is never up to the getting-well point. The first great step then is to try and bring them up to that point. Syphilis demands the quiet effects of mercury. I am aware that I differ with many of my brethren in the treatment of syphilis, but I believe that the poison of syphilis can only be removed from the system in almost all cases by the judicious and wise use of mercury. This mercury is to be used wisely and in moderate doses, so as not to impair the vigor and health of the system. Very often it is important to make use of some tonic at the same time, such as quinine or the preparations of bark. These have been my convictions for a great many years, and I give them as the result of my own practical observation, and have never seen any reason to vary the conviction, that iodide of potassium alone cannot overcome the syphilitic poison in the system. The iodide of potassium, however, is a very valuable remedy in the treatment of syphilis, but it comes in after we have accomplished our purpose with mercury, in order to remove any deleterious effects of mercury which may be left in the system. Here its value cannot be overestimated. The powerful effect which the iodide of potassium has upon the system, especially where mercury has been employed pretty freely, is sometimes seen in the profuse ptyalism which it produces, and if the syphilis receives any benefit from the administration of iodide of potassium, I believe it is in those cases which have heretofore been treated with mercury and the iodide arouses the mercury to new action. You can remove mercury from the system by the use of iodide of potassium, but you can never remove syphilis by using it. At the same time we use iodide of potassium in order to get good results in the system, I almost always employ the iodide of iron, as you see in this case. The point is, as has been stated, to bring the system up to par. The usual formula which I employ consists in six drachms of the iodide of potassium, one ounce of syrup iodide of iron, and make a six or eight ounce mixture. When this man first came here he was exsanguineous, and had a hang-dog look, but now his face looks ruddy and his system is fast getting into the proper condition for the manufacture of good blood. His system is being brought up, and now if he injures himself in any way, proper reparative processes will at once be instituted. The plan which I adopt and recommend in the treatment of syphilis is as follows:—Take a case of genuine Hunterian chancre. I commence with the administration of iodide of mercury in one-half grain doses twice in twenty-four hours, combined with something, perhaps hyoscyamus or lactucarium, to prevent irritation of the mucous membrane of the intestinal canal. Continue this, in connection with a true diet, consisting of simple plain material and such as will produce healthy blood, embracing breadstuffs, eggs, milk, and meat twice a day, and, cutting off entirely tobacco and all alcoholic drinks, continue the doses until the feeling of hardness about the chancre is all gone. Then stop the remedy, and watch the patient. If the disease begins to come out in the system, manifesting itself by glandular enlargements, diseases of the skin, affections of the fauces, or any one of these evidences, which shows that the poison is still in the system, resume the mercury as before and continue it until the disease has again passed away. It will be necessary to watch these patients for a long time, at least for months, and perhaps for a couple of years or more.

KRAUT.—Prof. Kraut of the University of Gottingen died recently, aged 72.

Reports of Hospitals.

CHARITY HOSPITAL, N. Y.

NOTES OF PRACTICE AND PECULIARITIES IN TREATMENT.

PNEUMONIA.

THE plan of treatment for pneumonia which finds most favor, is that by quinine and carbonate of ammonia. The patients are given from the first about 15 grs. of quinine per day, in 5 gr. doses, and 6 grs. of carbonate of ammonia every two hours. The oil-silk jacket is looked upon favorably, especially when bronchitis is present. The quinine is given for its tonic and anti-cell producing effect, and the carbonate of ammonia, not so much to retain the fibrin in a fluid condition as for its stimulant effect.

Alimentation is to be carefully attended to, and the patients are to be well nourished. With this plan of treatment the report is that the patients do remarkably well.

PHTHISIS.

The general therapeutics in these cases are such as the profession are already familiar with. The only new remedy which has been employed for the relief of the night-sweats is the tr. of belladonna, given in ordinary doses, once or twice a day. This remedy has given very satisfactory results in all the cases in which it has been used.

For the purpose of subduing the fever, which in some cases becomes the most prominent symptom for treatment, Heim's pill has been used with excellent results:

℞. Pulv. herb. digitalis, ℈ss.
Pulv. rad. ipecac,
Pulv. opii puri, āā grs. v.
Extract helenii q. s. u. f. pill No. xx.
Consp. pulv. rad. ind. flor.
S. a pill three times daily.

To control the diarrhœa which sometimes appears, salicine has been used with better success than any other remedy which has been employed. It is given in ten-grain doses every four hours, either in the form of pill or powder, as most agreeable to the patient. Dr. Drake, House Physician, who introduced it into the hospital, has treated seven cases by the use of salicine, which had resisted every form of treatment which had been adopted, and cured every one of them. What is equally satisfactory is, they have remained cured. Salicine has therefore come to be one of the methods of treatment for chronic diarrhœa, whatever cause it may be dependent upon, or with whatever disease it may be associated. There are occasional cases which do not respond to this remedy; but in general, the results have been far more satisfactory than with the use of any other remedy.

SPASMODIC ASTHMA.

Nitrite of Amyl is considered very good, but the prescription ordinarily used is a drachm of Ct. Spts. of Ether with ten minims of Tr. Belladonna three times a day. This mixture may be continued for weeks, and many patients improve markedly under its influence.

HÆMOPTYSIS.

When the patient has a sudden attack, the local application of ice or cold sponges over the surface of the chest are mainly relied upon.

In these troublesome cases, where blood is expectorated, more or less in quantity, every two or three days, or once a week and so on, some of the patients have tr. ergot in half-drachm doses three times a day, and in some instances they have received marked benefit from the use of this remedy.

Inhalations of balsam of tolu and sesquichloride of iron. The quantity usually employed is

℞. Balsam tolu, ʒ j.
Sesquichloride of iron, ℥ ij.
Water, O j.

In that class of cases to which reference has been made, these inhalations allay the irritation, and act in a very beneficial manner.

SUB-ACUTE PLEURISY.

Tapping has rarely been resorted to here, for the reason that it has been rendered unnecessary by the method of treatment adopted in these cases. Blisters and diuretics, and with these tonics, constitute an essential adjuvant. The tonics most generally employed are quinine and iron. With this plan of treatment, paracentesis thoracis is an operation but rarely seen.

ACUTE ARTICULAR RHEUMATISM.

Opium in sufficient quantities to procure relief from pain, with the use of the "alkaline treatment," are the constitutional measures usually employed, and nitrate of potash and wine of colchicum-seeds is a favorite prescription, and in some cases seems to have the preference, when compared with the pure alkaline treatment. The topical applications for the joints are to immediately paint them with tr. iodine, cover with cotton, and over this oil-silk. Renew this every day. With all these elements at work thoroughly, the doctors expect to overcome all the acute symptoms at least, and in most cases the disease entirely, within four or five days.

BRIGHT'S DISEASE.

The plan of treatment for this formidable malady is the union of the diuretic and tonic plan.

The agents employed are the infusion of digitalis combined with bitartrate of potassa, and quinine and iron as tonics.

When œdema of the lower extremities is present, the hot-air bath is the common means employed for its removal, in addition to the constitutional measures already indicated.

Progress of Medical Science.

THE CAUSE OF COLLAPSE IN DIPHTHERIA.—Professor Mosler, of Greifswalde, has published two cases of sudden collapse during apparent recovery from diphtheria. They give a somewhat different theory for the cause of death than has been urged by Trousseau. In fact this complication is barely mentioned by the latter author. Niemeyer describes such cases as those whose general condition has not excited much apprehension, or, in fact, has been regarded as satisfactory until, without warning of any kind, they fell into a collapse. In other cases still, profound syncope has occurred a number of times, at last ending in death.

A great deal of discussion has taken place with regard to the implication of the nervous system in the pathological changes, but in many cases no lesion whatever could be discovered. Wagner was the first to call attention to the fact that in these cases there was usually some change in the muscular tissue of the heart.

In the two cases cited by Mosler collapse was sud-

den and unexpected, the first taking place on the fifteenth, and the second on the fifth day. In both of them the walls of the heart were found dilated, and the seat of fatty degeneration. The trabeculæ in each case were flattened down.

The author makes the practical deduction that this demonstrates how necessary it is to adopt a tonic and stimulant method in treating this disease.—*Archiv der Heilkunde*, 1873.

The Relation between Intestinal Hemorrhage in Typhoid Fever and Cold-water Affusions.—Wunderlich, of Leipsic, has published an interesting reply to the opponents of this mode of treatment, and makes special reference to 18 cases in which this complication occurred in his father's clinic, between the years 1868 and 1872. Of 253 cases, the whole number treated during that time by various methods, intestinal hemorrhage occurred in 18, or in 7.1 per cent. It occurred, moreover, in 16 out of 155 cases treated by cold water, or in a little over 10 per cent.

These apparently unfavorable statistics are believed to be exceptional and dependent on other causes than this particular method of treatment. For example, four of these cases occurred in the comparatively short space of time between the 27th of September, 1868, and the 14th of November of the same year. For the subsequent three years only two such cases occurred, while the remaining 12 fell between the 30th of June, 1871, and the 20th of April, 1872. He adds that it is well known how certain epidemics show a marked prominence of special symptoms. This was true in Algiers; for of two epidemics one exhibited intestinal hemorrhage in two per cent. of the cases, and the other in 28.6 per cent., and the treatment in both was identical. Further, if cold applications cause such hyperæmia, we should expect that the blood would escape when the vessels were under the greatest pressure. In the six cases already mentioned only three had hemorrhage that could in any way be ascribed to the bath, and then it occurred after a lapse of some hours, while in the other cases after fully half a day.

The following statistics of mortality from typhoid fever with enterorrhagia have been compiled for the time preceding the introduction of this treatment—the name of the observer in each case is added:—Reinhard, 47.4 per cent.; Griesinger, 31.2 per cent.; Gietl, 50 per cent.; Vienna Hosp. Reports, 50 per cent.; Murchison, 35 per cent.; Betke (Bremen), 42.9.

Now, on the other hand, the statistics show a far more favorable result for treatment, the mortality, according to recent returns, being only 11.1 per cent., and no one of these cases died in consequence of hemorrhage. Of the 16 cases to which allusion has been made, the author believes that the hydropathic treatment was a powerful factor in insuring a favorable issue.—*Archiv der Heilkunde*, vi., 1872.

New Views in regard to Chlorosis and Puerperal Endocarditis.—Virchow in a recent article opposes the common idea that chlorosis results from an imperfect formation of the blood elements, and thinks that it may be due to anomalies in the vascular system. In these cases, he says, the heart and large vessels are not as fully developed as they usually are in persons of good health. This condition he usually finds associated with either an imperfect or an excessive development of the sexual organs. Still, as this is not always the case in chlorotic persons, and as the manifestations of the disease may appear before puberty and continue through and after pregnancy, we must look elsewhere for an explanation of the cause of the trouble, and he accordingly inclines to the belief that chlorosis stands in intimate relation with the more constant and permanent abnormities of the vascular system. The arteries, in these cases, are small and have thin walls, and give off irregular branches; this is especially true of the intercostals. The inner coat of these vessels, too, has a curiously undulating or fenestrated appearance, and is inclined to fatty degeneration; the middle coat and the muscular tissue of the heart are less often affected. As to the mechanical effect of the diminished size of the heart and vessels, there may still be no disturbance of the circulation, provided the blood be also diminished in quantity; but if greater quantities be produced, aortic pressure will increase, and dilatation and hypertrophy of the heart will ensue. The pressure in the peripheral vessels may then become excessive, and this may account for the frequent occurrence in such persons of the hemorrhagic diathesis, purpura, metrorrhagia, and chronic ulcer of the stomach. This imperfect development of the vessels, or hypoplasia, as it may be called, is frequently associated with an endocarditis of the valves. The left auriculoventricular orifice is affected by preference, and less often the aortic valve. The instances of endocarditis that occur in puerperal women, and produce such severe and dangerous complications, are more frequent than has hitherto been supposed. In most cases we can discover coincident disease of the uterus or adjacent organs; but there are cases in which puerperal endocarditis exists, and where the generative organs are perfectly normal.

Formerly death in such cases was regarded as due to pyæmic metastases. It is true we have sometimes to do with the occurrence of an old endocarditis which may return during pregnancy or parturition. The post-mortem changes are hard to recognize in pure valvular endocarditis, for the surface of the valves appears intact; the morbid process consists in a thickening of the endocardium. At first there are no heart murmurs and no local symptoms. In a short time, however, there appear over the affected spot warty or polypoid clots of blood, or there are ulcers formed by the dissolution of the effete matter, and then emboli are found in the spleen, kidneys, retina, and choroid.

There is another kind of endocarditis that is associated with puerperal disease. In these forms there is really a diphtheritic membrane formed, and it seems to be situated on a previously diseased portion of the valve. The cause of this affection is obscure.—*Berl. Beitrag. zur Gynaekologie*, 1, 3.

A Cure for Diabetes Mellitus.—Professors Cantani and Primavera, of Naples, report the most extraordinary success in their treatment of this obstinate disease. Their statements are in brief as follows:

1. Their patients have all, with rare exceptions, recovered.

2. Stout persons have lost but little weight during the treatment, while spare ones have sometimes gained as much as twenty-five pounds.

3. Though the urine has become rich in urea and uric acid, the patients have never shown symptoms of gout or urinary calculi.

4. The treatment was also successful in arresting some instances of albuminuria that accompanied the disease.

5. The cure consists in an exclusive meat diet, and by this term fish is also included; further, at each meal is to be taken lactic acid ♏ij–iv in water ℥ vj. As a substitute for wine at dinner, alcohol ℥ ss. with water ℥ vj is given.

Alcohol and lactic acid are designed to replace the

saccharine and starchy elements of the food. To obtain a permanent cure it is necessary to persist in the treatment for several months after sugar has ceased in the urine. Then the patient may gradually return to a mixed diet.—*Allgemein. Med. Central. Zeitung*, 1873.

THE LYMPHATICS OF THE BRAIN DURING INCREASED ARTERIAL PRESSURE.—Gaethgens, of Dorpat, believes that sudden pressure in the vessels of the brain is followed by a corresponding escape of fluid from the perivascular spaces through the lymphatics. Taking horses for his experiments, he opened both the carotid and the large lymphatics of the neck. After observing the amount of lymph that was escaping through the lymphatics, he injected the carotid with some warmed and defibrinated blood under high pressure. In each experiment it was found that during and immediately after injecting the carotid there was a remarkable increase in the flow of lymph.

The suddenness of the increase would seem to indicate that it was not due to increased transudation from the vessels into the perivascular spaces, but rather to the mechanical pressure.

This may explain how force is distributed when for any reason the vessels are subjected to unusual tension. If the same force acts for a longer time it will naturally lead to œdema and compression of the brain.—*Allgemein. Med. Central. Zeitung, Feb.*, 1873.

STRYCHNIA AND ITS PHYSIOLOGICAL ANTAGONISTS.—Schroff has made some interesting observations in the Pharmacological Institute of Vienna, and his conclusions as to the antagonism between strychnia and its various supposed antidotes are somewhat different from those that have heretofore been reached.

In these experiments he employed an aqueous solution of the nitrate of strychnia, each cubic centimetre of water containing two milligrammes of the poison. He found that a single milligramme of strychnia used in this way was sufficient to kill a frog, while it required fifteen milligrammes to kill a rabbit.

Having administered poisonous doses to these animals, he tested the efficacy of such reputed antidotes as physostigma, bromide of potassium, aconitia, the methyl compounds of strychnia, and the hydrate of chloral.

It will be remembered that there are two recorded cases in which physostigma has been successfully used. In one of these cases Keyworth saved the life of a woman who had taken three grains of strychnia. He employed the tincture of the alkaloid in thirty-drop doses. In the second case, Newman, by giving one-sixth grain doses of the extract of Calabar bean, moderated spasms which were apparently due to strychnia.

The results of the experiments in these cases were formulated as follows:—

1. That the Calabar bean moderates the tetanic spasms, but

2. That it does not defer the fatal termination, in one case rather accelerating it.

The interest which attached to the alleged antagonism between strychnia and the bromide of potassium was due to the success reported by Gillespie and Hewlett.

The experiments in this case resulted negatively; in fact, death seemed sometimes to be hastened by the bromide.

In regard to the action of aconitia, it was found that whether large or small doses were given, the phenomena of strychnia poisoning were never entirely obscured. Entire absence of reflex action seemed to follow most rapidly when both alkaloids were administered simultaneously. In the larger doses death followed from aconite poisoning.

Woorara was also tested, and poisonous doses were given in one case before, in a second during, and in a third after, a poisonous dose of strychnia. In none of these cases, however, did the woorara arrest the tetanic spasms, but in one instance the characteristic actions of both poisons showed themselves side by side.

One experiment only was performed to test the methyl compounds of strychnia as antagonists of strychnia. The result was highly satisfactory. A poisonous dose of the methyl was followed by a non-poisonous one of strychnia, and the animal recovered in a few days.

The following observations were also made with regard to the hydrate of chloral:—

If strychnia be given to an animal during the deep narcotism of the hydrate, a poisonous dose of the former will be borne with impunity, but will not prevent a fatal termination, which will eventually take place through a gradual failing of the respiration.

Many of the statements now published by the author he wishes regarded as preliminary, but he hopes by further experiment to be able to establish them more satisfactorily.—*Med. Jahrbuecher*, iv., 1872.

CATARRHAL SALPINGITIS.—Prof. Carl Hennig, M.D. D., of Leipzig (*Am. Jour. of Obstetrics*), has an important paper on "Catarrh of the Fallopian Tubes —Catarrhal Salpingitis"—an affection very common, and, of the various catarrhs of the genital organs, occurs the most frequently. Whether, under ordinary circumstances, tubal secretion flows into the cavity of the uterus, he states, is still an undecided question. Having examined 103 subjects with reference to catarrh of the internal genital organs, he found that in 41 cases the mucous membrane of the tubes, 31 of the body of the uterus, 43 of the cervix uteri, and 27 of the vagina, was in the catarrhal condition. For the most part, both tubes are affected; the left is more often singly affected than the right. In 27 cases both were affected; in 10 the left, in 7 the right; among 86 tubes examined, 69 of the whole were catarrhally affected. In regard to complications of tubal catarrh, in 24 cases evidences of peritoneal inflammation were present, which in seven of them had not ceased; one case showed not only the results of previous peritonitis, but also an endocarditis, pneumonia of the right side, icterus and ecchymosis of the liver, chronic nephritis, and eczema of the skin. In six women, ascites was met with. Adhesion of the ovary to the diseased tube occurred eight times; to intestines, once; to the uterus, once. In connection with anomalies of the ovary it was found in 23 cases, etc. Tubal catarrh, as long as it does not produce a perforating ulcer, is not fatal. It is otherwise with the sympathetic and secondary catarrh.

The life of the prostitute, and probably the period of pregnancy, are the most productive fields for tubal catarrh; the puerperal state the least productive. Married women are less often exempt than all individuals past the menopause in the various social positions. Widows are less seldom spared than children. Chaste women are more subject to catarrh than the prostitutes, the young, and the married. In concluding, he considers it interesting, that of married women before the menopause, less than half, and after the same, more than half, are affected.

THROMBOSIS OF THE ARTERIES OF THE EXTREMITIES.—John A. Liddell, M.D., of New York (*Am. Jour. Med. Sciences*, Jan. 1873) has a lengthy article in which he

discusses, mainly from a clinical stand-point, thrombosis as it occurs in the systemic arteries, especially those which belong to the extremities.

By way of introduction, he asserts that the blood does spontaneously coagulate in the peripheral arteries during life, as he has shown that it not unfrequently does in the peripheral veins, or, in other words, systemic arterial thrombosis does take place. Thrombosis of the arteries of the extremities has been observed much more frequently in connection with the so-called spontaneous gangrene of the aged than with any other disorder. Two cases are reported which afford a good illustration of the relation which subsists between arterial thrombosis and senile gangrene. A case is reported, affording an illustration of another variety, namely, that in which the coagulation primarily occurs, not in the terminal branches, but in the main artery of the limb. A case related by Romberg describes a third variety, that of *secondary arterial* thrombosis.

In describing the clinical relations of thrombosis of the arteries of the extremities, he mentions, with cases, the following several diseases in connection with which it has been found to occur: Puerperal Gangrene; Rheumatic Gangrene; Ulceratvie Endocarditis; Asiatic Cholera; Pleuro-pneumonia; Typhus and other forms of continued fever; Constitutional Syphilis. Inflammation of the parts surrounding large arteries and veins may sometimes be attended with thrombosis of these vessels.

No period of life is exempt from the occurrence of thrombosis of the systemic arteries.

Ovariotomy.—J. Marion Sims, M.D., of New York, in a recent number of the *N. Y. Medical Journal*, has an extended paper in which he claims that the majority of the fatal cases of ovariotomy are caused by septicæmia. To substantiate his opinion he presents the records of thirty-nine fatal cases taken from the first 115 operations made by Mr. Spencer Wells; of these, the latter gentleman interpreted the causes of death as follows: Intestinal obstruction, 1; tetanus, 2; pyæmia, 2; heart-clot, 3; exhaustion, 7; peritonitis, 12; septicæmia, 7; not stated, 5. Total, 39. Dr. Sims makes the causes as, Tetanus, 2; pyæmia, 3; septicæmia, 34. Whenever in the progress of a case, after operation, there was a discharge of reddish serum beside the pedicle, he put it down as septicæmia. In every one of the author's seven post-mortem examinations, and in every one of Mr. Wells, twenty-six, there was a quantity of reddish serum, or grayish turbid serum, or fetid serum, or putrid serum, or acrimonious serum, in the peritoneal cavity; and in cases slowly dying of pyæmia, pyogenic reservoirs are found in the pelvic cavity. He thinks it is logical to infer that these pent-up fluids are the causes of the blood-poisoning that so uniformly and universally attends the fatal cases of ovariotomy. Dr. Sims gives Dr. Peaslee credit for the principle of intra-peritoneal medication which was originated by the latter, and only claims to be his coadjutor. But the rule that he would establish for exceptional cases, Dr. Sims would wish to make applicable to all alike; and instead of washing out the peritoneal cavity at the top, he proposes to open it at the bottom, as he did in 1855, and let the fluids run out spontaneously and continuously. The natural outlet of the peritoneal cavity is through the Douglas *cul-de-sac*. Dr. T. Parvin, of Indianapolis, Ind. (*Am. Practitioner*, Nov. 1872), in reviewing three cases of ovariotomy, is impressed wtth the value of a preliminary tapping in cases of ovarian dropsy when the tumor is large. The tumor by its immense size has seriously disturbed vital functions. Lessen its size, so that that interference may be temporarily at an end, and the patient may rally and recruit her forces. And again, it is less violence to remove a mass of ten or twenty pounds than one of forty, fifty, or sixty. Possibly or probably the patient's chances of recovery are increased in proportion as the size of the tumor is diminished. Finally, for the purpose of diagnosis, a preliminary tapping is of great value. As to the method of securing the pedicle, he believes, when the length is sufficient, there is nothing so simple, so easy, and so efficient as the clamp.

Thrombus of Left Ventricle, with Pulmonary Apoplexy and Rupture of Thoracic Duct.—W. W. Munson, M.D., Otisco, Onondago County, New York, relates the following case: C. E. B. Male, aged 18 years. Previous health good. I was called in the night of October 10, 1872, with report that patient had "difficulty of breathing." Arrived about 12 o'clock P. M. Found great dyspnœa with tumultuous action of heart, face livid, pupils dilated to a mere rim—not responsive to light, conscious. He had been suffering for a few days from a slight attack of indigestion, with vomiting and diarrhœa, which was readily controlled with bismuth and astringents.

Mother stated that at about 11 o'clock of the night in question, he called her with this complaint of "jerking in his breathing," and that he had been very restless during the previous day, going from couch to bed and back every few minutes.

After I had been in the house about fifteen minutes, dyspnœa suddenly increased, and immediately blood and contents of stomach gushed from mouth and nose with great force, and he was dead instantly, making but two violent efforts in as many breaths, as one dying of strangulation.

Made autopsy in presence of Dr. J. Kneeland of South Onondaga. Found large thrombus in right ventricle, firmly attached to tricuspid valve and its tendinous and muscular cords, extending into pulmonary artery an inch or so. Inferior cava, superior cava and its immediate branches firmly obstructed with coagula. A large rent was found in lower lobe of left lung, opening into a pleural sac, which contained four or five ounces of blood. Right pleural cavity also contained blood. Lungs otherwise healthy.

But the most interesting feature of the case is this: On opening abdominal cavity we found several ounces of a milky appearing fluid which, by separating stomach and transverse colon, could be seen oozing up from below. Stomach and bowels were carefully examined for perforation, but none was found, nor did either contain any such substance; both perfectly healthy. Then we thought there must be an abscess, but none was found. At last we discovered a large rupture of the thoracic duct, just behind the pancreas, probably produced in the violent efforts of the death agony—the left subclavian, along with the other branches of descending cava, being engorged, obstructing opening from thoracic duct.

No embolus was *found* in branches of left pulmonary artery to cause the laceration of lung; neither could we account for the hemorrhage into right pleura, probably produced, however, by rupture of some small thoracic veins which escaped detection.

Query: Is it possible that the efforts in suffocation produced by the thrombosis were sufficiently violent of themselves to cause so general a laceration of tissues which were not in any way degenerated by disease?

Bronzing of the Skin.—H. C. Hand, M.D., of St. Paul, Minn. (*N. W. Med. & Surg. Jour.*, Jan., 1873), publishes a singular case of intense bronzing of the

skin of the entire body arising during pregnancy. The patient was an unmarried Irish girl, æt. 21. She, having been thrust from her home in the North of Ireland, arrived in Philadelphia penniless and friendless. She was delivered of a full term and healthy fœtus. From the time of its first appearance the discoloration of the skin gradually increased in intensity and territory, until at the time of delivery it had invaded the whole body. In the course of months the anæmia and prostration vanished and the darkness of her skin gradually faded away. The author suggests that her grief was an active agent in producing the pigment changes of her skin, by modifying its nutrition through defective or faulty innervation. This query is raised: "When aided by the predisposing cause of gestation, why might not her skin turn dark from grief, as readily as the hair may turn white from grief or fear?"

Amputation at the Hip-joint.—A successful case of amputation at the hip-joint is related by A. E. Carothers, M.D., of Saltillo, Mexico, late Asst. Surg. U. S. Vols. (*Am. Jour. Med. Sciences*, Jan., 1873). The following are his closing remarks: Where gunshot fracture of the trochanters, neck or head of the femur is complicated by wound of the great vessels of the thigh, or where they are included in a slough of the wound causing secondary hemorrhage, it is the duty of the surgeon to give the patient the chance for life that lies in amputation at the hip-joint.

ARTICLES IN OUR EXCHANGES.

PRACTICAL MEDICINE AND PATHOLOGY.

Series of cases of organic heart-disease. Alfred Stille. *Northwestern Med. and Surg. Jour.*, April.

On diseases of the throat. Knight, F. I. *Boston Med. and Surg. Jour.*, April 3.

On the epidemic influenza. Various Authors. *Med. and Surg. Reporter*, April 5.

Extensive abscess of the abdominal cavity. Constantinides, P. C. *Canada Lancet*, April.

On thrombosis of the cerebral arteries. Lidell, John A. *Am. Jour. Med. Sciences*, April, 1873.

An inquiry into the nature of the yellow-fever poison, etc. Sternberg, George M. *Am. Jour. Med. Sciences*, April, 1873.

Typhoid fever, lesions and treatment. Rhett, Benjamin. *Charleston Med. Jour. and Review*, April.

Case of tubercular meningitis. Ross, George. *Canada Med. and Surg. Jour.*, April.

Pathology, causes, course and treatment of rheumatism. Whitmire, James S. *Chicago Med. Jour.*, April.

The character of phthisical hæmoptysis. Dutcher, A. P. *Cin. Med. News*, April.

Paresis of the cerebral arteries. Kennedy, Stiles. *Review of Medicine and Pharmacy*, April.

Functional disease of the heart. Davis, N. S. *Med. Examiner*, April 1.

The case of a patient with a history of syphilis, and a blow on the head, having died with phthisis. Carson, Wm. *The Clinic*, April 5.

Thermometry in cerebro-spinal meningitis. Rodenstein, C. F. *Archives Scientific and Practical Medicine*, March.

Plastic exudation within the pleura—dry pleurisy. Leaming, J. Rosebrugh. *Archives Scientific and Practical Medicine*, March.

Inhibitory arrest of the act of sneezing, and its therapeutical applications. Seguin, E. C. *Ibid.*

On a rare cause of mistake in testing urine for albumen by the ordinary processes. Brown-Séquard, C. E. *Ibid.*

Variola; observations during the last epidemic. Kersch, S. *Memorabilien*, 2, 1873.

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, May 1, 1873.

SHALL WE HAVE ANOTHER AMERICAN MEDICAL ASSOCIATION?

THE present meeting of the American Medical Association in St. Louis invests the question of the practicability of reorganizing that body with much interest. For several years past there has been a feeling that this organization is very far from representing the profession of America, so far indeed that with few exceptions there is hardly a medical man in the country who is not thoroughly disgusted with its workings and heartily ashamed of the reputation it has earned. At one time to speak against any policy of the Association, or to criticise its doings, or to question its motives, was considered so heretical that it required all the moral courage which a firm conviction of being in the right gave to the critic. When we first took occasion to refer to its proceedings as being farcical, undignified and unworthy of the high aims of a body claiming to guard the best interests of our brotherhood, we recollect how much righteous indignation was uttered against us. Now, however, as the question has been taken up and discussed by many of the leading medical journals, all of whom agree that the Association as such has proved itself a failure, we feel that we have not written in vain; that we did not take the weaker side of this argument. We are now convinced that the time has come when the profession throughout the land are ready to entertain the question of a thorough reorganization of the society, and are willing to make an effort to give it that power and usefulness which should rightly belong to it. Many have gone so far as to give up all hopes of resuscitating it, and to propose a new organization in its stead. Although we believe that many radical and sweeping changes are necessary, we are willing to try the effect of restoratives a little while longer, believing that by this method there may be left a chance of lifting this so-called representative body from the disgraceful lethargy into which it has fallen.

We have always maintained that one of the great drawbacks to the Association has been the cheapness of its delegateship. So cheap has it of late become that it goes a begging. It has not been a question whether or not any one could go, but whether they would go. The consequence has been that very few of the solid representative men ever attend any of the meetings, and the important questions which may come up, and which have such an immense influence upon the good name of medicine, are left to be decided by incompetent upstarts and irresponsible bunglers. As we have so often said before, let there be fewer delegates, let there be the most stringent rules providing for their election, and let it be considered an honor to be elected. The suggestions of Dr. PROUT, of Brooklyn, which we publish in another column, are deserving of consideration in this connection. We commend them to the attention of all interested in the question of creditable delegateship. Although his method is far from being perfect, it presents many striking points of practicability. We can at least seize upon it as a starting-point. We care not how the question of delegateship is settled provided that we attain the results so anxiously, so imperatively desired.

We have also shown on previous occasions why newspaper reporters should be excluded, and why the suggestion of Dr. DAVIS, of Chicago, that the Association print its own proceedings, is a good one (MEDICAL RECORD, vol. viii., p. 85). We trust that the Association may act accordingly.

Another point to which we wish to call attention, and one which it is of the greatest importance to consider, is the necessity of having a large and carefully selected Committee of Ethics. Every year we have one or more test questions sprung upon the Association. As a rule only a few interested parties are prepared to discuss them, and we have an exhibition of the disgraceful scenes which have of late made the Association famous as an undignified, quarrelsome and stultified body. Now if all doubtful points, all important ethical questions, could be left entirely to this committee, composed, as it should be, of our best men, men whose opinion the whole profession respect, they could in a majority of instances be disposed of at once. If this committee cannot be unanimous in the expression of their views, let them make a majority and minority report, so that the Association can see the true issues at stake and be prepared to vote accordingly. This, it strikes us, is one way to insure that careful, impartial, and thorough examination into all "the weightier matters of the law" which their great importance to the present and future welfare of the profession demands.

Among all who have written on the subject during the past few months, no one has come so near to our

own views as Dr. Gross, of Philadelphia. In a letter to the *Medical Times* (April 5) he submits a plan of reorganization that is substantially a modification of the plan we propose. Dr. Gross, who is one of the oldest members of the Association, and who has given, as he states, "anxious deliberation" to the subject, accords with us in these three propositions:—

1. That the Association must reorganize or disband. 2. That ethical questions and miscellaneous business of all kinds should, so far as possible, be kept out of the public meetings of the Association. 3. That the membership should be somewhat restricted.

In regard to the details of the method of correcting these two evils we differ, but our general objects are the same, and the plans are not so far apart that they cannot be harmonized. Dr. Gross proposes the appointment of a medical council of ten members, residing at or near the place of meeting, to whom shall be referred all questions of ethics and other miscellaneous business, and their decision shall be final. We agree with this proposition, but the number of members of the council is too small.

A council sufficiently large, and composed of representatives from all parts of the country, would represent the profession of the *whole* country. They could meet a day or two before the Association meets, hold private meetings daily during the session, and on the last day, perhaps, bring in their reports. It is not probable that all the members of a council thus constituted would ever meet, but out of thirty or more members there would be at least a majority. Dr. Gross must himself see that a body of ten men in St. Louis are not competent to decide the destinies of an Association composed of physicians from all parts of the country. There is no necessity for quarterly meetings, as he suggests. Let them correspond by circular during the year, and when they come together their labors will be comparatively easy.

On this subject we are not theorizing; the plan we propose is a practical one; it has been and is carried out in many of our smaller societies, and with success, and this made their sessions most satisfactory. Dr. Gross further proposes to have the Association admit members only through the State societies. We believe that it would be more practicable and every way better to allow the county and other societies to send delegates as heretofore, excluding medical colleges, hospitals, and charitable institutions of every kind. The advantage of this arrangement would be, that the county and other societies, which are really of greater importance to the well-being of the profession than large organizations like the American Medical Association or State societies, will be better sustained, and the members will labor in them and for them in order that they may deserve and receive the honor of delegateship.

As an experiment the transactions have proved a failure not only in a scientific but in a pecuniary way, and unless we can make some change for the better in both respects we are in favor of confining their utility to the mere publication of the minutes, leaving the valuable papers to be disposed of as promptly as possible in the different medical journals of the country. By such means authors can come before large audiences, and their ideas can become the property of the profession at least within the year in which the pretentious and expensive volume of transactions is expected.

We do not, however, pretend to speak of all the changes necessary to be made in the organization of the Association to place it in the position which it should hold, but only desire to call attention at this time to one or two which, it strikes us, are of sufficient importance to engage the attention of the Association at its next meeting. Doubtless other suggestions equally good will be advanced by others, and if they are considered more practical, more comprehensive, and more salutary in their general influence upon the profession, we hope that they will receive every consideration. We are not ambitious to see any particular theories of our own adopted, our sole aim in entering the discussion being to redeem the Association and cause it to reflect the sentiments of the advanced professional mind of the present. Let us make a determined and conscientious effort to bring about such a result, and if this be impossible, we are then willing to accept the ultimatum of the demise of the Association, and at the same time congratulate the profession that it has freed itself from an incubus which has been weighing down its very life for the past ten years.

In conclusion, let us hope that the meeting at St. Louis will be signalized by the incorporation of all the changes in the organization which shall insure for it the countenance and respect of the entire American profession. We believe that the fate of the Association hangs on the meeting at St. Louis. Will its founders and friends be equal to the emergency?

THE MEDICAL AND SURGICAL HISTORY OF THE WAR OF THE REBELLION.

We repeat the recommendation made in the previous number, that the American Medical Association petition Congress for an appropriation to publish an edition of this great work, large enough to place a copy in the hands of every medical officer and private physician who has served during the late war, and also to furnish copies for sale at cost. In addition, let a vote of thanks be passed to Congress for what it has already done, and also to Surgeon-General J. K. Barnes, U. S. A., and the accomplished and scholarly compilers and editors. The profession, as a body, cannot express itself too emphatically on these points.

THE MEDICAL HEALTH COMMISSIONERS.

If the new health department is actually created, there will be but one medical gentleman to be ap-

pointed as Health Commissioner. It is a matter of a good deal of importance that he shall be a thoroughly representative man. The Health Officer of the port, whose appointment as the other medical member is provided for by the act, will receive the indorsement of the profession. Let us hope that an equally responsible one will be found as his associate. The means to such an end will, in our opinion, be the retirement from public life of the present Health Commissioners, neither of whom have met the expectations of their brethren. As to the chiefs of the new bureaux, nothing better can be done than to have the old ones reappointed. This would be the most substantial tribute to their praiseworthy endeavors to discharge the grave responsibilities of their respective offices.

THE SANITARY SUPERINTENDENT OF THE BOARD OF EDUCATION.

We are pleased to note that Dr. R. J. O'Sullivan is again a candidate for the position of Sanitary Superintendent of the Board of Education. He is a gentleman eminently fitted for the position, having for many years past given close attention to sanitary affairs relating to the common-school system. The indorsement of the medical profession as represented by the presidents of the different medical societies, and other prominent physicians, is well merited, and should command the serious attention of the appointing power.

PHYSICIANS IN PUBLIC OFFICES.

With one or two exceptions, every one of the newly created school districts is represented by a member of the medical profession. This is as it should be, and proves that the profession is beginning to take an interest in the management of public affairs, which as representatives of an educated class they should have done long ago.

THE PROSPECTIVE HEALTH DEPARTMENT.

The new charter creates a Health Department composed of four commissioners, two lay and two medical. The former consists of the President of the Board of Police, and a layman who is to be President of the Board; the latter of the Health Officer and another medical gentleman. The bureaux to be continued are those of registration and sanitary inspection, as before. It is expressly provided that a medical man shall not be president. Why the bare possibility of a physician being chosen to such an office should have prompted our lawgivers to offer the gratuitous insult to our profession, of enacting that under no circumstances should such a thing occur, does not appear.

If the charter receives the approval of the Governor (which at the time of our going to press it has not), we shall have more to say concerning some of its provisions.

Reviews and Notices of Books.

THE PATHOLOGY, DIAGNOSIS AND TREATMENT OF DISEASES OF WOMEN, INCLUDING THE DIAGNOSIS OF PREGNANCY. By GRAILLY HEWITT, M.D., Lond., F. R.C.P., Prof. Midwifery and Diseases of Women, University College, and Obstetric Physician to the Hospital. &c. &c. Second American from the Third London edition; revised and enlarged with One Hundred and Thirty-two Illustrations. Octavo, pp. 741. Philadelphia, Lindsay & Blakiston. December, 1872.

AFTER a fitting dedication to Sir Charles Locke, the first sentence of the preface reads: "This new edition of my Treatise on the Diseases of Women is substantially a new work." We desire to confirm this statement, and to add that it is a very great improvement upon all previous editions.

The experience of the author for the last five or six years has led him to become a radical and earnest votary of the "Mechanical System of Uterine Pathology." Throughout this large volume this is the controlling idea. Mechanical displacement of the uterus in its three forms of Flexion, Version, and Descent, is in his mind the key to all or almost all the abnormalities of the nutritive, menstrual, secretory, sanguimotor, and nervous functions. In order not to misrepresent the author we will borrow his own statements upon the subject: "Patients suffering from symptoms referable to the uterus are almost universally found to be affected with flexions or alterations in the shape of the uterus of easily recognized character, but varying in degree."

"The change in the form and shape of the uterus is frequently brought about in consequence of the tissues of the uterus being previously in a state of unusual softness, or what may be often correctly designated as chronic inflammation.

"The flexion once produced is not only liable to perpetuate itself, but continue to act incessantly as the cause of the chronic inflammation present.

"Logically and practically there are good reasons for placing the flexions first in the order of sequence. Admitting the powerful predisposition to flexion produced by a soft condition of the uterus, that softness is not always of the nature of inflammation, for flexion, not uncommonly, as after parturition, may be brought about by over-straining; the uterus being simply softer and larger than usual. Accidents or over-exertions frequently give rise to flexions in the non-gravid state, without any decided evidence of previous uterine inflammation.

"It is not intended to be inferred that all uterine pathology involves is a study of flexions, their relations to inflammation, and *vice versâ*. The uterus is liable to other pathological processes having no relation of a tangible character to either flexion or inflammation, *e.g.*, cancer, fibroid tumors, &c. But regarding the large majority of actual cases it is nevertheless true that these flexions and consequent inflammations have a very preponderating influence."

In support of these propositions he reviews the entire uterine practice of the University College Hospital, as observed and directed by himself during the last four years.

Of 1,205 cases upon the books, 491 were those of disease of the external generative organs, the breasts, the ovaries, and conditions dependent upon pregnancy; leaving 714 cases properly classed as uterine. In 90 of these no examination was obtained; the remaining 624 were the more severe cases, and in them diag-

nosis was definitely made by physical examinations, as follows: Ante-flexion, 184; Retro-flexion, 112; Prolapsus, 81 (or 377 cases of displacement in the total of 624); Fibroid tumors and polypi, 96; cancer, 54!!; Pelvic cellulitis, 32; or 182 cases of organic nature; leaving 65 to distribute among Menorrhagia, Amenorrhœa, Hæmatocele, Hypertrophy of Cervix, Leucorrhœa, Climacteric disorders, &c. &c.

Reviewing these statistics, we remark: 1st. That, accepting the author's diagnosis, we think his conclusion of the preponderating influence of displacements is fully sustained by them. 2d. That other authors with minds preoccupied with other ideas would probably have classed these cases very differently; *e.g.*, to J. Henry Bennett they would mostly have been inflammation and hypertrophy, to Chapman (latest of American authors) they would mostly have been congestion.

3d. That in our opinion Dr. Hewitt, ably, and in the main justly, goes behind these secondary and derived conditions to the prime cause of the morbid phenomena in displacements—probably erring, however, in not allowing congestion to precede displacement in the order of time as often as the facts warrant.

4th. We are disposed to believe that in estimating ante-flexions and ante-versions sufficient allowance is not made for the normal varieties of the forward inclination of the uterus.

Thus, in the girl before puberty, the uterus is constantly ante-verted—and during menstrual life, if the longitudinal axis of the body of the uterus being produced upward should issue in the median line, and not more than 2½ inches below the umbilicus, we should not consider that anterior displacement existed. We should not accept Dr. Hewitt's opinion, that when the intra-vaginal portion occupies the axis of the superior strait of the pelvis, and the body of the uterus can be felt above the anterior vaginal cul-de-sac, morbid anteflexion exists.

Conversely, we should not describe as morbid any retroflexion in which the axis of the body of the uterus did not fall behind the axis of the trunk—unless there were decided symptoms of discomfort or disorder of function.

5th. The proportion of cases of cancer (54 in 1,205) seems to us very large—no parallel for it existing in our experience or observation.

On pages 35 and 36 we have copied from Dr. Farre three very instructive plates, the study of which will do much towards correcting ideas of uterine pathology in the minds of students; and on page 37 a statement of great importance, more clearly made by Dr. Hewitt than by any other author with whom we are familiar, viz.: that the primary effect of congestion upon the tissues of the uterus is to cause *softening* and *increased pliability*. This is the condition in which flexions very commonly are acquired. Endometritis as a separate and distinct phenomenon Dr. Hewitt regards as rare in the extreme, but very common as the result of any condition which obstructs the cervical outlet, such as flexions, hypertrophic elongations of the cervix, and such softening of the cervix as allows its tube to collapse—also any obstructive adventitious growths, as polypus, fibroids, epithelioma, cancer, &c., &c.

In common with most modern authors Hewitt lays little stress on "Ulcerations of the Os," regarding the condition as generally but a symptom, and the term as very commonly misapplied. Acute inflammation of the uterus from other than traumatic causes he considers extremely rare. Chronic congestions and so-called chronic inflammation he considers as best managed by constitutional treatment, local depletion and the sparing use of milder caustics, but believes that many of the cases depend upon flexions and are best treated by removal of the cause.

Chaps. iv. and v. are occupied with the methods of exploring the Pelvis and its Viscera. The teaching is sufficient and sound but presents nothing new. Chap. vi., pp. 146–192, treats of the diagnosis of Pregnancy. It is comprehensive and well written, and embraces some points not often adverted to.

Chaps. viii.–xiv. treat of Flexions, Prolapse and Inversion. The subjects are illustrated by admirable plates, which seem to us more satisfactory than those usually employed. They teach us how Congestion, Chronic Inflammation, Endometritis, Hypertrophy, Dysmenorrhœa, Amenorrhœa, Metrorrhagia and Abortion, with their whole train of subjective symptoms, may and often do depend upon these mechanical causes.

The chapter on Inversion is not so full as the subject warrants, and does not detail many of the mechanical expedients found useful in reinversion, such as the dimpling of the fundus, elastic pressure, incision of the cervix, the repositor of Dr. White, or the exceptional intra-abdominal dilatation of Prof. Thomas.

In repositing the flexed uterus Hewitt appears to employ only the ordinary Simpson's sound, which for such uses has, with us, long been superseded by Sims' Repositor or the still more beautiful articulated instrument devised by Emmet.

In the general treatment of flexions he assigns much importance to the dilatation of the cervical canal, asserting that moderate anteflexions are often cured by this means alone. For the retention of the rectified uterus he employs intra-vaginal pessaries, occasionally the intra-uterine stem, which he mounts upon his ordinary ring-pessary. The instrument which he commonly employs is known among us by his name. It is a copper wire ring covered with gutta-percha, varying in diameter from 2½ to 4½ inches, and so malleable that it may be put into any shape. The shape employed for retroversion is the elongated and double-curved oval familiar to us in "Hodges' Closed Lever" and the "Albert Smith."

Dr. Hewitt's instrument is little used among us, the ring of plain block-tin being preferred on account of its greater cleanliness and permanence, and the hard rubber instrument chosen in preference to either on account of lightness, cleanliness and comparative freedom from the danger of producing ulceration of the vagina. For anteversion he bends a ring of large diameter into a shape to which he gives the name of the Cradle Pessary. The peculiarity being that while one end of the instrument occupies the posterior cul-de-sac, two shoulders rise up to occupy and extend the exterior cul-de-sac, while the remainder of the instrument follows down the anterior wall of the vagina and finds its fulcrum on the inner surface of the symphysis.

The subject of Pessaries is a very important one. While there are still some who decry their use, we are sure that such are neither the majority nor the best informed portion of the profession.

In our observation more signal and more frequent advantage follows their use than any other single proceeding in gynæcological therapeutics. Such evidently is Dr. Hewitt's opinion. The great variety of instruments, some of them of the most absurd character, and the constant crop of new forms which are yearly added to the list, attest the ingenuity and the imperfect success of the profession in this field.

The section upon the natural supports of the uterus and the forces which antagonize displacement is a very full and just discussion of the subject. The operation for removing the vagina, as done by Sims, Emmet and Thomas, is discussed without conclusion as to the final

value of the proceeding, a matter upon which, we believe, the projectors are not now sanguine. Amenorrhœa, Dysmenorrhœa, Meno- and Metrorrhagia are fully and fairly discussed, but the essay upon Chlorosis is not up to the mark of recent studies of that subject. The chapter on nervous disorders referable to the uterus is excellent; of course he finds that flexions are the most frequent occasion, and even asserts that the condition which the classic treatise of Gooch on Irritable Uterus illustrates, is pretty uniformly flexion with its attendant congestion. Hypertrophy, atrophy and the undeveloped uterus are discussed at length, but the author does not commit himself upon the vexed question whether there is ever an increase of tissue in the non-parturient uterus. Vaginal discharges, Hæmatocele, Cellulitis, cancer are critically studied.

Ovarian tumors occupy a considerable portion of the volume, but the abundant and exhaustive treatises of Wells, Peaslee and Atlee occupy this ground so much more fully that no one would think of studying them only in a systematic work upon diseases of women. In the account of the operation we notice what is either a grave mistake or a misprint in the direction that a temperature of 60° should be maintained in the room during the operation. We are not aware that the clamps invented by Dr. Hewitt have been much used by others. The objection to them would seem to be that they involve too much stitching of the pedicle. In common with other operators Dr. H. prefers the clamp where the length of the pedicle permits its use. Diseases of the bladder of the external generative organs and vesico-vaginal fistula occupy the remainder of the book. Dr. H. does not recognize, as our American specialists do, the harmlessness and the great advantage of incisions from the vagina into the bladder for the cure of calculus, cystitis, etc. He also seems to be unacquainted with the value of the electro-caustic methods of treatment, now so highly appreciated among us.

The style of our author is not free from ambiguities and repetitions. The book is larger than it need have been, but in its arrangement as well as in its teaching it is a great improvement upon the previous edition, and is, as a whole, equal in value to any of the recent systematic treatises on this subject. As we have before said, the plates are unusually instructive and valuable, and the general appearance of the book is creditable to the publishers. Future editions will undoubtedly appear and will command the attention due to the excellent opportunities, the diligence, the acumen, and the candor of the author.

ON THE FUNCTIONAL DISEASES OF THE RENAL, URINARY, AND REPRODUCTIVE ORGANS, with a general review of Urinary Pathology. By D. CAMPBELL BLACK, M.D., L.R.C.S., Edin., Member of the General Council of the University of Glasgow, Author of "Observations on Therapeutics and Disease;" "On Certain Points in the Pathology and Treatment of Gonorrhœa;" "On Syphilitic and Phagedænic Ulceration," etc., etc. Philadelphia: Lindsay & Blakiston, 1872.

IT is to be regretted that the author has not given more space to the first three chapters of this most excellent little work. As it is, they contain a complete summary of the most advanced views on "The conditions that affect the secretion of urine, with special reference to suppression;" "Retention of Urine, its Varieties, Causes, and Treatment," and "Irritable Bladder and Strangury."

The remaining chapters embrace the entire subject of spermatorrhœa and its accompanying disorders. The disinclination of professional men to give their attention to functional diseases of the male generative organs is deplored, and, on the other hand, their too exhaustive consideration of the corresponding diseases of the female is pointed out.

The arguments adduced in favor of sexual intercourse as a physical as well as a psychical necessity are strong and incisive, and the propositions of the moralists in regard to the beneficial effects of the act when *licensed*, and, *per contra*, its baleful influences when *non-licensed*, are aptly met and ably overthrown. Says the author: "Patients who are tormented with nocturnal emissions, and cannot marry, are advised, forsooth, to diminish secretion. Go to the raging sea and say, 'Be still!' . . . . . As well tell a man with jaundice to diminish his biliary secretion, or the unfortunate victim of diabetes to arrest the diuresis which constitutes a notable feature of his disease."

The term Spermatorrhœa is objected to in the following language: "I would suggest that the term Spermatorrhœa be at once and forever expunged from medical literature. Beside being a misnomer, it has an abominable ring. Spermorrhagia more aptly expresses the meaning of the term which should be employed."

In the concluding chapter non-specific urethral discharges and their differential diagnosis are discussed, and several instructive cases are related.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, Jan. 22, 1873.

DR. ERSKINE MASON, PRESIDENT, in the Chair.

TUMOR OF BRAIN.

DR. FINNEL exhibited a specimen of tumor of the brain embedded in the substance of the left middle lobe, and read the following history prepared by Dr. Matthew C. O'Connor:

Thomas Lynch, 35 years of age—born in Ireland—railroad laborer by occupation—married. This patient enjoyed good health until five months previous to admission to St. Vincent's Hospital, when he commenced to have constant headache, which he attributed to exposure to sun during the summer, his work as railroad laborer requiring him to be a great deal exposed. About three weeks afterwards the headache became more severe, quite suddenly, and it continued very severe since that time. His eyesight began to fail soon after this. He would vomit frequently, during the week previous to admission, almost every day. His smell began to be affected: shortly after he noticed his sight failing. Two months before admission had to take to bed. Denied explicitly ever having any venereal trouble.

He was admitted to St. Vincent's on November 1st. On admission he gave the above history. The pain he described as more severe over left side of head, and particularly so at occiput. His appetite was impaired and bowels costive. Pupils dilated, left slightly more than right. Pulse 60.

Next day after admission his pulse was found to be 45 and full. About two weeks after admission his eyesight failed completely. He would lie in bed with his eyes shut, and would only open them when told, the pupils not responding to light, then would quickly close them.

He vomited almost every time he took food, until about two weeks before death, when it ceased.

He had occasionally slight delirium, more marked at night. He did not sleep well, but took short dozes. Bowels were always constipated, requiring occasional injections.

He had no hemiplegia nor paralysis of facial muscles, except about two days before death, when paralysis of left orbicularis palpebrarum was noticed. Hearing unaffected.

His pulse at each observation was found invariably to be more frequent and weaker than at the preceding, until December 12th, two days before death, when it reached 150. At this time he gradually became comatose, with stertorous breathing, and died on December 14th. He was treated with iodide of potassium.

Post-mortem five hours after death. Body somewhat emaciated. Cranium alone opened. Pacchionian depressions well marked. Dura mater normal.

The specimen was, on motion, referred to the Committee on Microscopy.

Dr. Briddon remarked that it was not uncommon for cerebral tumors of slow growth to be unaccompanied by paralysis of the motor nerves. He had on a previous occasion presented a cancer growing from the base of the skull in which the larger lobe of the left hemisphere was involved. In that case sight was destroyed five years before death, smell two years, and taste for a much shorter period. There was no paralysis until immediately before death, when compression took place from the inflammatory action around the tumor.

MULBERRY CALCULUS LITHOTRITY SUPPLEMENTED BY LITHOTOMY.

Dr. Briddon next exhibited calculi removed by the operations of lithotrity and of lithotomy. The following was the history of the specimens.

The patient, a Baptist minister, aged 67 years and eight months, was referred to me in October, 1872, by Prof. Charles A. Budd. He had been suffering from symptoms referred to his bladder for the period of six or seven years, such symptoms consisting in the occasional frequent desire to urinate. During the last year his sufferings have been more permanent and pronounced, and at the time of his coming under observation he had to empty his bladder every two hours during the day, but was not much disturbed during the night; considerable pain during and after the act. This pain was in the organ involved, and in the glans. Urine was sp. gr. 1020. React. acid, and it contained neither albumen nor casts. He had no enlargement of the prostate, but for some reason, which I could not at the time explain, I made two careful explorations before I was able to satisfy myself of the presence of stone. October 15th, in the presence of Dr. John Howe, I introduced a lithotrite, and in the reversed oblique position I succeeded in closing the blades on a calculus less than an inch in diameter. Found on closing the blades it was not sensible of fracture, but as the instrument had been two or three minutes in the bladder I removed it, and there was a very small fragment of concretion adhering to the blades.

This operation, though conducted with the greatest care and gentleness, was followed by rigors and profuse perspirations.

October 22d introduced lithotrite; searched very carefully through all the positions of Civiale, but could not even detect the stone; this operation was followed by a succession of rigors and perspirations, and the patient was very weak and shaky for a week.

The difficulty and uncertainty of finding the calculus; the increasing irritability of the bladder, and the tendency to rigors, determined me to substitute lithotomy for crushing; and the operation was done on the 7th of January, 1873, in the presence of Profs. Budd, Mason, and others, and the stone was removed without difficulty worthy of note. After its extraction I searched the cavity for pouch or diverticula, to account for the difficulty I had frequently experienced in detecting the stone when exploring with sound or lithotrite. The bladder was not sacculated, it was unusually large, and its thickened lining membrane in large voluminous folds, sheltered behind which I could easily conceive it possible for a small concretion to elude the most careful manipulations.

The calculus was composed of oxalate of lime, incrusted with a layer of phosphates more than a quarter of an inch thick, the whole weighing ninety-nine grains.

In the afternoon of the day upon which the operation was performed the patient had one severe and several smaller rigors; he was ordered five-grain doses of the sulphate of quinine in conjunction with morphia. On the following day was in good condition, and his subsequent recovery was uninterrupted by accident of any kind.

CURIOUS CASE OF ENGORGEMENT OF THYROID BODY.

Dr. Delafield presented a specimen taken from a patient with the following history:

A gentleman, æt. 52, had always enjoyed good health, and was not conscious of anything abnormal about himself, except that he had for 20 years a small goitre on the right side of his neck. It had never given him any trouble, and it was a thing to which he had not paid any special attention. On the 22d of June, while eating his dinner, he suddenly, without apparent cause, choked over a piece of meat. From that day forth until the time of his death he was never able to eat any solids. There was no further change from the 22d of June until the 3d of October, when he noticed that the goitre was becoming enlarged, and at the same time was beginning to be painful. This condition continued for two days, when also without cause he was attacked with acute suppurative inflammation of both eyes. For this trouble the patient sought relief in the Eye Infirmary, where he was under the care of Dr. Althof. The disease ran a rapid course, both corneæ sloughed, and the contents of the eyes were discharged. He was then transferred to the Roosevelt Hospital, on the 29th of October. It was then noticed that the tumor on the right side of the neck was decreasing, and at the same time there was less difficulty in swallowing, although the patient was still unable to swallow solid food. On the 17th of November the tumor seemed to have disappeared. The difficulty in swallowing, however, remained about the same. With these symptoms he had occasional vomiting. He grew weaker and weaker, and a few days before his death he developed symptoms of gangrene of the lung, and died January 9. When the patient was admitted to the Eye Infirmary the principal attention was directed to his eyes; when admitted to the Roosevelt Hospital the principal attention was directed to the tumor in his neck, but further than this his case was not inquired into as particularly as it might have been. Dr. Delafield's care of the case ceased just when the tumor was commencing to decrease.

At the autopsy the brain was found normal. The eyes were found reduced to stumps. The ophthalmic arteries and veins, and the larger veins on the cranium connected with these, were examined with considerable

care, but nothing was found to account for the curious suppurative inflammation attacking both eyes. The right lung was found the seat of gangrene in a portion of its upper lobe the size of a hen's egg, and around this the lung was hepatized. There were also one or two small spots of gangrene in the lower lobe of the same lung. The heart, otherwise normal in appearance, was much reduced in size, evidently owing to the severity and the long continuance of his disease. The liver, kidneys, spleen, and intestines presented nothing abnormal.

On examining the neck the thyroid gland on the left side was enlarged, and extended down below the clavicle. On the right side where the tumor had existed the thyroid gland was rather small, and in the soft tissues surrounding it there were found some thin layers of yellow material, presumably dry pus. The wall of the œsophagus opposite the bifurcation of the trachea was destroyed for the space of an inch and a half long, embracing pretty nearly the entire circumference of the tube. It was destroyed by an ulceration which has opened into both bronchial tubes. The edges are ragged and very little thickened. On minute examination it was found that there was some infiltration in the neighborhood—in a word, that the ulcer was cancerous in character.

The trachea presented nothing abnormal until the bifurcation was reached, when an opening was found in both bronchi.

The autopsy only threw light upon one symptom, that is, the difficulty of swallowing, due to the tumor, which in its turn was occasioned by inflammatory processes.

EXCISION OE ELBOW—EXPEDIENCY OF TREPHINING OLECRANON.

Dr. Sayre presented a specimen of excised elbow-joint removed by operation for suppurative disease of the part, of eighteen months' standing, the result of an injury. The case made a very rapid recovery. He desired to call attention to the condition of the olecranon, illustrating by its numerous perforations. Nature's effort to discharge the contents of the joint. The question occurred to him whether it would not be well to imitate nature in this regard by trephining the olecranon.

Dr. Briddon asked if, in such an operation, there was not more danger from bony anchylosis than if a clean exsection were made.

Dr. Sayre remarked that the operation would be of course an experiment, but his recent successes in boring into the ankle would encourage him to do the same thing with the elbow when an opportunity should offer.

MORBUS COXARIUS—EXSECTION, ETC.

He also exhibited a head of femur, &c., removed, four weeks before, from a boy nine years of age, who had morbus coxarius for three years. The patient was removed from the wire-breeches the Sunday previous. At the time of making the report the patient was walking about on crutches.

Another similar specimen was exhibited, removed from a patient that afternoon at Bellevue Hospital. Said patient was a boy aged five years, who had suffered from hip-disease for two years, the result of a fall. The head and neck of the femur were entirely destroyed. The trochanter major presented a large carious abscess, which was opened, giving exit to the matter. The acetabulum was perforated. At the bottom of a sinuous tract, on the external aspect of the thigh, was a small spiculum of bone which was discovered while attempting to evacuate the said sinus of its contents.

He remarked, in conclusion, that this was his forty-first case. Of this number he had lost but eight—seven in the first twenty, and but one in the last twenty.

The Society then went into Executive Session.

Stated Meeting, February 12, 1873.

Dr. Erskine Mason, President, in the Chair.

MISCELLANEOUS SPECIMENS.

Dr. Lewis A. Sayre presented to the Society the patient from whom he removed the first and about half of the second phalanx of the thumb (1¼ inch in all) for necrosis following a neglected felon. The man had recovered with his thumb but little shortened, and with an artificial joint. The voluntary movements of the last phalanx were nearly as good as on the sound side.

EXSECTION OF ELBOW, ETC.

At the same time the before-mentioned specimens were exhibited he showed also the fragments of bone taken from an elbow which he had exsected. He could now report that, six weeks after the operation, the wounds had completely healed, and that the voluntary movements were now almost perfect.

Dr. Sayre next exhibited a great toe which had been removed from a gentleman who had suffered for the past eighteen months with suppuration of the tarso-phalangeal joint, caused by dancing with a tight boot. Abscesses had formed and eight fragments of necrosed bone had been discharged. The Doctor said he would have undertaken to form a false joint, as in the case of the thumb, had not the patient lived at too great a distance from the city to admit of the care necessary during the after-treatment.

MORBUS COXARIUS.

Next the Doctor presented two specimens of the remains of the heads and necks of two femora, both of which had been removed that afternoon. The first case was a boy nine years old, who for six years past had been suffering from hip-disease resulting from a fall. For a year and a half the child had been going about, and had improved very much in his general health; but an abscess existed behind the trochanter major, and from it was a daily discharge of pus.

On making an incision down to the bone, it was discovered that the whole of the head and most of the neck of the femur were gone; the acetabulum had become perforated, and an abscess which was discovered to exist inside the ilium, being limited by the periosteum, communicated with the one above mentioned. The pus from these sources gushed out when the capsule was divided at the point of its insertion at the inter trochanteric line.

The abscess extended down the inner side of the bone, which was cut by the saw, just above the trochanter minor.

The second case was that of a little girl of thirteen, who had fallen when about two and a half years old, and received an injury which resulted in hip-disease. A discharge of matter from sinuses on the inner side of the thigh, near the groin, had been going on for some time.

At the time of the operation the limb was adducted, flexed, and fixed. The operation was done at the desire of the mother, who could not afford the time and expense of caring for the child during the long time it would take to bring about a discharge of the dead bone if the cure had been left to nature. Furthermore, the limb would not have been as useful as after an operation for the immediate removal of the

diseased tissues; for, in Dr. Sayre's experience, cases in which such an operation has been performed give better results as regards usefulness of the limbs. At the operation it was found that the head and neck of the femur were almost completely gone, a fragment the size of the last phalanx of a thumb representing all that remained of the latter; and, what was unique in the doctor's experience, the acetabulum had become filled with new material, and a new facet had formed above it, on which the upper extremity of the femur rested, being still embraced by the proper capsule, which had become displaced with it, and no luxation out of the capsule had ever taken place. The abscess had extended down into the bone-tissue on the inner side of the femur, but had not yet perforated the medullary canal.

These were the forty-second and forty-third cases in which Dr. Sayre had performed this operation, and all the cases excepting these have been in patients who were at the time of the operation almost in *articulo mortis*, and the operation had been made as a last resort. These patients, on the contrary, were able to go about, and were in a pretty fair condition as regards their general health. Of these forty-three cases only eight have died, and six of the deaths occurred among the first twenty cases. The cases were not picked ones, and in those in which the result was fatal the death did not appear to be hastened by the operation.

Both the patients were put into wire breeches.

Dr. Finnell asked if Dr. Sayre ever exsected the head of the femur when anchylosis had taken place.

Dr. Sayre said he never did it unless for the correction of deformity; and in such cases he would make a new joint, by cutting a section of bone from the healthy tissue, according to the method he had already published. When anchylosis has taken place, and the position of the limb is good, he attempts no operation at all.

GLIOMA OF RETINA—EXTIRPATION OF EYE.

Dr. Knapp presented an eyeball removed by him from a child two months ago, and which presented a glioma of the retina. The disease was first noticed six months before its removal, and two months later was shown to an oculist. It is not known whether an operation was advised or not. When Dr. Knapp saw the child for the first time, the eyeball was enlarged, inflamed, hard, and protruding. The anterior chamber was shallow; the pupil large and immovable, the lens transparent, and the vitreous chamber filled with a dirty, yellowish substance. As the diagnosis was evident, an immediate operation was advised and consented to, and was at once executed. It was found that there was an episcleral tumor around the optic nerve, which itself was thickened, and, therefore, another piece of it, as far as it could be reached in the orbit, was excised. The specimen presented to the Society showed the ordinary condition of glioma, or encephaloid tumor of the eye. It filled the entire vitreous chamber, and formed an additional tumor on the outside of the sclerotic of about the size of an almond.

As could have been anticipated, a relapse of the pseudoplasm followed soon. A tumor in the temple, on the side of the extirpated eye, of a softish consistence, in immovable connection with the bone, grew in two months to the size of a goose's egg. Several other smaller tumors made their appearance at other parts of the skull.

Two weeks after the operation, a local recurrence was noticeable in the orbit, which increased very rapidly in size, ulcerated, and bled freely. Another tumor, apparently of the same nature, developed in about the centre of the right half of the lower jaw. The child died from exhaustion a little more than two months after the extirpation, and Dr. Knapp was able to present to the Society its skull. The calvaria showed, on its inner side, a great number of vascular exostoses, arranged like walls around free spaces which looked like depressions on the inner table of the skull. Corresponding to these crater-like depressions, there was a great number of hemispherical, soft, extremely vascular little tumors on the outer surface of the dura mater. There were six or eight subperiosteal tumors in both the temporal and frontal regions, and another one on the right lower jaw, which had been noticed during life. The bone corresponding to the largest of these tumors, situated in the right temple, was rough, reddish, and thinned. There was another one on the inner table of the cranium, inseparably connected with the dura mater. The cranium itself was healthy, but somewhat corroded in the right temporal region.

The nature of all these tumors Dr. Knapp pronounced to be that of a very vascular glioma—the so-called fungus hæmatodes of earlier writers. The epicranial tumors, and those on the outside of the dura mater, being unconnected with one another and the original retinal tumor, must, the Doctor thought, warrant their being considered metastatic.

There are only four or five instances of gliomatous metastases on record. The picture of the present case in its outward appearance greatly resembled that of the first case of the kind, which was described by the Doctor in his treatise on intraocular tumors. It differed from the same, however, as the metastatic tumors did not originate in the diploë of the bones, but were subperiosteal. Recently, another case had been shown at the Philadelphia Pathological Society by Dr. Norris, which, to judge from the short description in *The Medical Times*, should be identical with the specimen exhibited by Dr. Knapp.

With regard to the prognosis in the case of gliomatous tumors in general, the Doctor mentioned that they were exceedingly malignant; yet some few cases were on record in which relapses have not occurred. He had extirpated more than three years ago, in this city, an eyeball affected with glioma of the retina, and the boy does not, as yet, show any symptoms of its recurrence or of ill-health. These observations seem to confirm the notion that the initial stage of glioma is benign.

EPITHELIOMA OF LEFT EYELIDS.

Dr. Knapp next introduced a patient suffering with epithelioma of the left eyelids, from whom he hopes to remove the disease, preserving the eyeball, and constructing new lids. The first pimple was noticed fifteen or sixteen years ago, and was very slow in its growth until eighteen months ago, since when the ulceration has attacked the bone in the lachrymal region. Dr. Knapp thought the tumor extended to the apex of the orbit, which was usually the case when they had attained a size like the one presented; but he hoped to preserve the eyeball, though, perhaps, half of it might be denuded. Certain tumors, called cylindroma, are found in this region, and are very prone to relapse.

NEW YORK ACADEMY OF MEDICINE.

Stated Meetings, February 20 and March 6, 1873.

Dr. Ellsworth Eliot, President, in the Chair.

At the Stated Meeting, held February 20th, Prof. Henry D. Noyes, M.D., made some interesting remarks

on the "Indications for General Pathology in the Diseases of the Eye," with illustrations by the magic lantern.

THORACENTESIS.

Dr. Chas. A. Leale, at the Stated Meeting, held March 6th, read an important paper on "Thoracentesis," based on recorded cases occurring during the past eight years, and closed with these conclusions:

After carefully considering the subsequent histories of all the patients on whom I have performed thoracentesis during the past eight years, it has proved successful in every instance, either by not only preventing death, preceded by the most agonizing symptoms that the physician is called upon to witness, but in the majority of instances we may confidently hope a restoration to at least very good health.

We should, as in tracheotomy and abdominal paracentesis, prefer to use the scalpel to open the chest. 1st. As a safer procedure. 2d. An incised wound is known to heal—if required—with greater certainty. 3d. By using a long male silver catheter, the most dependent part of the chest can be emptied of its fluid contents, and there is no danger of pricking the lung from change of position or movement of patient while the liquid is being withdrawn, as noted by Dr. Allbut. 4th. When pus has commenced to undergo that change preparatory to absorption, the probabilities are, that very little, if any, will be reproduced after the operation, if the wound is immediately closed. 5th. That in closing the wound under the above circumstances, the little atmospheric air admitted, and the small quantity of pus left behind, are very soon absorbed. 6th. That if pus should again accumulate in the chest, the operation is so easy, the pain so slight, and the closure so rapidly accomplished, that a repetition is nothing to be feared, and really causes less prostration than perhaps sometimes where a large incision is made, and perhaps pus formed with greater rapidity. 7th. That atmospheric air, pus and blood, even to the extent of about eight ounces, may be absorbed, and that the injured compressed lung can again resume its normal condition, as so conclusively proven by the recorded post-mortem examination. 8th. That when unhealthy decomposition has commenced, the wounds should be left open and the parts carefully disinfected. 9th. That thoracentesis should oftener be performed for the quick removal of fluid from the chest, even in far advanced phthisis pulmonalis; when relief may be obtained, life prolonged, and painful death averted.

Dr. Peaslee referred to the importance of the paper, and to the fact that he performed paracentesis and thoracentesis on a patient, in 1851, before Dr. Bowditch reported his cases. A full history of the case was given.

The President stated that he had notes of twenty cases of thoracentesis, although his cases for the last two or three years had not been recorded. In one case the operation was performed 5 times; in another 3 times; and in 8 cases, twice—either with Dr. Bowditch's instrument, or the author's adaptation of Davidson's syringe; nine of his cases were fatal; but, even in these, the operation gave relief. Pneumo-hydrothorax existed in 4 cases. In not one of the 20 cases did the operation fail to produce relief, or was there any bad effect. He thought that the operation was useful in some cases of pulmonary tuberculosis, giving expansion to the lungs. If we knew the patient had pneumo-hydrothorax before the operation, it would be questionable whether the operation should be performed, without there was a good deal of dyspnœa.

Dr. Peaslee inquired if he had operated in cases of hydropericardium, and received a negative reply. The President remarked that it had been done, but could not recall cases. He would not hesitate to do it.

In answer to the question of Dr. A. C. Post, whether hydro-pneumothorax was not always, or necessarily fatal, he said that the prospect of recovery in cases of great dyspnœa was very small, but recovery sometimes took place, and related a case in point.

The following donations to the library were announced: Two copies of the U. S. Marine Hospital Service, for 1872; copy of the Edinburgh Medical Journal.

The resignation of Dr. P. W. McDonnell, as a Resident Fellow, was unanimously accepted.

The President stated that at the next meeting a paper on "Galen and Paracelsus" would be read by Prof. J. C. Dalton, M.D. Dr. Wm. Detmold would also describe a new method of "Treating Facial Paralysis."

The Academy then adjourned.

Stated Meeting, April 3, 1873.

Dr. Austin Flint, President, in the Chair.

Drs. Leroy Milton Yale, John J. Mason, and Cornelius R. Bogert were elected Resident Fellows.

On motion of Dr. Alfred C. Post, Drs. S. S. Purple and W. C. Roberts were appointed a committee to draft resolutions on the death of the late Josiah C. Nott, M.D., a Fellow of the Academy, who died March 31, in Mobile, Alabama.

OPIUM—ACUTE URÆMIA.

Prof. Alfred L. Loomis read a lengthy paper on "Acute Uræmia," which will be published in full in our columns. He showed that morphia, injected hypodermically, is a proper and safe remedy in cases of acute uræmia.

Dr. Chamberlain, at the suggestion of Dr. Peugnet, had employed in two cases of this disease the benzoate of ammonia for neutralizing and eliminating the poison from the system. In a case which was seen by Drs. Loomis and Flint, the remedy was given when the patient was in a stupid state; in a short time there was increased urination. As yet he could not speak with much emphasis concerning the value of this remedy.

Dr. Anderson mentioned a case of spasms, occurring six hours after confinement, which was relieved by a full dose of calomel followed by an injection of turpentine. The previous administration of ether only partly relieved the patient.

Dr. Hubbard was pleased with Dr. Loomis' paper, and should in the future employ the hypodermic injection in this class of cases. In puerperal eclampsia, he was sick and tired of chloroform, but would advocate the infusion of digitalis and, in some cases, bleeding. He had had but little experience with uræmic convulsions.

Dr. J. W. Richards was happy to hear that opium was beneficial in controlling convulsions, and that the author of the paper, the son of one of his old playmates, was advocating the use of it. Two cases of hysterical convulsions were related, occurring in his practice, which were controlled by large doses of this agent. In one case he gave forty grains of opium and two ounces of laudanum in one night, which, he facetiously remarked, "almost controlled the convulsion." He saw no impropriety, but *propriety* in the use of opium in cases of acute uræmia, and in connection venesection.

The President introduced Dr. James P. White, of Buffalo, who returned thanks for the privilege of meet-

ing with the academicians, and stated that in some cases of puerperal convulsions he would not confine himself to hypodermic injections. Perhaps the profession were riding the hypodermic hobby a little too hard. Although we had been told that opium could not be given in cases of cerebral obstruction, the President would recollect a case which occurred at Black Rock, more than a quarter of a century ago, in which an enemata of opium controlled the convulsion. Since 1851 he has been in the habit of giving in some form an opiate, in conjunction with an anæsthetic, to control the convulsions. It was important, as Dr. Anderson had remarked, "to let off the steam," but calomel was not as good as other remedies; croton oil, prepared with sugar and placed on the tongue, was an effective agent. It irritates the mucous membrane of the entire intestinal canal, proving a revulsive. The theory of Braun, that every patient with convulsions was in an anæmic condition, he could not accept; consequently, he would perform venesection occasionally.

The Academy then adjourned.

Correspondence.

REORGANIZATION OF THE AMERICAN MEDICAL ASSOCIATION.

To the Editor of the Medical Record.

Sir: As the matter of reorganizing the American Medical Association has been discussed in your columns, as well as in other journals, permit me to say that I think no better model for it can be found than our State Society. I therefore have drawn up, and propose the enclosed plan for its reconstruction. This is far from being complete, as I only want to point out a direction in which improvement can be had. If there is not some radical change soon made, I can only look forward to, and hope for the speedy death of an organization that, whether representing or misrepresenting us, does so much to make the profession in this country appear ridiculous.

Different views are held as to the proper work of the Association—one being that it should discuss scientific matters as well as govern the medical profession; another is, that it should simply be a governing, and not a scientific body. This is the opinion held by the Boston *Medical and Surgical Journal*, which proposes that it be composed of two delegates only from each State. If this view of its purpose is correct, then 309 delegates are many more than are needed. I am in favor of making the Association a scientific as well as a governing body.

It might also be well to consider whether the Association could not with advantage assume the charge of preparing the U. S. Pharmacopœia, and rescue it from the trade influences that seem to be acquiring control over it.

The following plan of organization would probably answer all good purposes:

The American Medical Association shall be composed of delegates and permanent members.

The Medical Society of each State may send as many delegates as the State has representatives in Congress, but any State that may have only one representative shall be entitled to send two delegates. The number of representatives is 292; one additional delegate from Delaware, Nebraska, Nevada, and Oregon (4) will give a total of delegates from States of 296.

In addition to those from the several State Societies, the following organizations shall be entitled to representation:

The Medical Society of District Columbia	2
The Medical Department U. S. Army	2
" " " " Navy	2
The U. S. Marine Hospital Department	1
The Association of Superintendents of Insane Asylums	2
The Association of Teachers in Medical Schools	2
The U.S. Pharmaceutical Association	2
Giving a total of delegates of	309

Ten permanent members may be elected annually in the following manner: the delegates from the different medical societies shall be divided into ten equal or nearly equal geographical sections. At each meeting each section may elect a permanent member, who shall reside in the part of the United States represented by the section, and who shall have attended two annual meetings as a delegate.

Permanent members shall have all the rights and privileges of delegates.

Delegates from the societies and associations named above, shall hold office for four years, except that of those first elected after this change takes effect; one-half shall hold two years, one-half of each delegation shall thereafter be elected every two years.

No State Society, after the year 1880, shall be entitled to representation unless it be composed of delegates from county societies, with or without the addition of permanent members, who shall have first served as delegates.

Meetings shall be held annually; each alternate meeting being held in New York City.

An annual assessment of $5 shall be made on each delegate and permanent member. Money required to carry on the work of the Association in excess of the amount thus received shall be assessed upon the several Societies represented in proportion to representation.

J. S. Prout, M.D.

Brooklyn, March 31, 1873.

ARMY NEWS.

Official List of Changes of Stations and duties of Officers of the Medical Department, U. S. Army, from April 5, 1873, to April 18, 1873.

White, Robert H., Assistant Surgeon.—Relieved from duty in the Department of the South and to report to the Commanding General Department of the Lakes, for assignment to duty. S. O. 74, A. G. O., April 9, 1873.

Kimball, J. P., Assistant Surgeon.—To proceed to Yancton, D. T., and report to the Commanding Officer, Battalion 7th Cavalry, for duty upon the Yellowstone Expedition. S. O. 64, Department of Dakota, April 2, 1873.

Corson, Joseph K., Assistant Surgeon.—To report in person to the Commanding General Department of the South, for assignment to duty. S. O. 74, c. s., A. G. O.

Matthews, W., Assistant Surgeon.—Relieved from duty at Willett's Point, N. Y. H., and to report in person to the Commanding General Department of the East, for assignment to duty. S. O. 78, A. G. O., April 12, 1873.

McMillin, Thomas, Assistant Surgeon.—Died, April 6, 1873, in Camp at Headquarters, Modoc Expedition.

Medical Items and News.

New York Medical Library and Journal Association.—At the stated reunion of this Association, held April 4, 1873, Dr. John C. Peters, President, in the Chair, Dr. R. A. Vance read a short paper on "The Ophthalmoscope as a means of Diagnosis in Tubercular Meningitis and the Diseases which simulate it." Drs. O. D. Pomeroy, T. R. Pooley, Wm. C. Roberts, and the President made remarks upon the paper. The following donations were announced:

The private library of Dr. John H. Griscom, LL.D., comprising 300 bound volumes and between 500 and 600 unbound journals and monographs, and 12 elegant anatomical plates, life size.

Pamphlets presented by Dr. J. H. Emerson.

Thomas's work on Diseases of Women, presented by the author.

Framed engraving of Sam'l L. Mitchell, M.D., LL.D., presented by the Librarian.

Transactions of the Medical Society, State of New York, 1872, presented by the President.

Framed portraits of deceased New York and American physicians are desired for the adornment of the walls of the Association; a large number have already been received.

Measures are now being taken to secure complete sets of the transactions of every medical society in the United States. Secretaries of the various medical societies are earnestly requested to send copies of transactions to the Librarian, 107 East 28th Street.

Home for Incurables.—The managers of the Home for Incurables, West Farms, N. Y., are erecting a commodious building, to cost about $100,000, on the estate of the late Jacob Lorillard, near Fordham.

Death of a Prominent English Microscopist.—Dr. Edward Latham Ormerod, F. R. S., of Brighton, England, an accomplished microscopist, died recently. His most important professional studies were on the diseases of the heart.

Prize Medal of the British Medical Association.—The Hastings gold medal, value twenty guineas, is offered annually by the British Medical Association as a prize for an essay on some subject connected with medical science. The subject for 1873 is: "On the Pathology and Treatment of Ovarian Diseases," and the award will be made at the annual meeting of the Association in August.

School of Medicine in Paris.—The following new appointments have taken place in the School of Medicine in Paris: M. Lozain is appointed Professor of the History of Medicine; M. Lefort, Professor of Practical Surgery; and M. Charcot, Professor of Pathological Anatomy.

Drug Stores in the United States.—There are 14,000 drug stores in the United States, and the number of persons employed in the various branches of the drug business is estimated at 135,000.

The Woman's Medical College of the New York Infirmary.—Dr. A. D. Rockwell is delivering a course of twelve lectures on electro-therapeutics in this institution.

Howard Hospital, Philadelphia, Pa.—The 19th annual meeting of the contributors to the Howard Hospital and Infirmary for Incurables was held March 31st, 1873. During the year ending March 1st, 1873, there were registered at the hospital 7,139 new patients. Of these, 2,727 were males and 4,412 females; 3,670 were Americans and 3,469 foreigners. The medical board is as follows:—*Physicians*—Drs. Joseph Klapp, A. Paul Turner, Wm. B. Atkinson, S. C. Brinckle, Thos. S. Harker, Horace Williams, Laurence Turnbull, and David Burpee. *Surgeons*—Drs. T. H. Andrews and Oscar H. Allis. *Resident Physician*—Dr. Wm. H. Parrish.

Decennial Catalogue of the Bellevue Hospital Medical College.—This elegantly-bound volume is entitled: the "First Decennial Catalogue of the Trustees, Faculty, Officers, and of the Alumni of the Bellevue Hospital Medical College, of the City of New York, from 1861 to 1871," and is compiled by Fred'k A. Castle, M.D., Historian of the Alumni Association. Dr. Leroy M. Yale gives the history of the school from its organization to 1872. The total number of names of graduates in the catalogue is 1,073. The names of 18 graduates, who have become irregular practitioners, are properly omitted. The tinted paper, clear type, and the general arrangement of the Catalogue have not been equalled by previous works of other similar organizations.

Registered Pharmacists.—The members of the New York Board of Pharmacy have published the list of 397 registered pharmacists in New York City, to January 25th, 1873, with their addresses. The names of 363 registered assistants are appended. The members of the Board are as follows:—Wm. Neergaard, M.D., President; Paul Balluff, Theobald Frohwein, Wm. Manlius Smith, M.D.; Francis H. Weismann, M.D., Secretary. Session for examinations, on Monday, Tuesday, and Wednesday, of the months of February, April, June, August, October, and December.

British Medical Association.—The annual meeting of this Association will be held this year in London. The sessions occur on the 6th, 7th, and 8th of August. The present roll of membership has upwards of five thousand members.

Society of the Presbyterian Hospital, N. Y.—The fifth annual meeting of this Society was held April 9th, 1873, in the chapel of the hospital building. Interesting addresses were made by Rev. Drs. Vermilyea and Hall. The report of the treasurer showed that of the proposed endowment fund ($250,000), all had been subscribed but $19,000.

Jefferson Medical College.—The faculty and alumni of this institution are very much disappointed over the failure of their application to the Pennsylvania State Legislature, for an appropriation towards the establishment of a hospital in connection with the school.

American Medical Association.—The Transactions of this Association, vol. 23, 1872, show, that since its organization in 1846, there have been 2,083 permanent members; of these 526 have died—leaving 1,557 living members.

New York Medical Association.—At the annual meeting of this Association, organized in 1849, the following officers were elected for 1873: *President*—J. Haven Emerson, M.D.; *Secretary*—Lucius D. Bulkley, M.D.; *Treasurer*—S. T. Hubbard, M.D.

New York College of Pharmacy.—Professor C. F. Chandler, Ph.D., delivered an interesting lecture on "Modern Pharmacy," April 17th, 1873, in the new lecture hall of the College, University Building, University Place.

Death of a French Medical Editor.—Dr. Marchal (de Calvi), the editor of the *Tribune Médicale de Paris*, died of apoplexy, February 24th, 1873, aged 57. He was successively the editor of the *Gazette des Hôpitaux*, *Revue Chirurgicale Française*, and the *Recueil des Mémoires de Médecine et de Chirurgie et de Pharmacie Militaires*. He was the author of the important work entitled, "*Recherches sur les Accidents Diabétiques, et Essai d'une Théorie générale des Diabètes.*"

Medical College Commencements.—The 31st annual commencement of the St. Louis Medical College took place March 12th, 1873. Diplomas were given to 60 graduates. At the 27th annual commencement of the Med. Dept. of the University of Buffalo, held February 25th, 1873, degrees were conferred upon 40 graduates.

Prizes.—M. Malherbe has been awarded the Prix Duval of the Society of Surgery of Paris for his researches on "*The Febrile Condition in Diseases of the Urinary Organs.*" The prize subject of the Society of Medicine and Surgery of Toulouse, for 1874, is as follows: "*On the purity of chemical medicines most commonly employed: indicate the most certain and easy tests.*"

The Medical Record of London, concerning which we have had something to say before, has changed its name to *The London Medical Record*. This is as it should be. There will now be no danger of confounding one journal with the other.

Liebig.—Baron von Liebig, the world-renowned chemist, died at Munich April 19th, 1873. He was seventy years of age.

Dr. James L. Brown.—The next number of the *Medical Record* will contain the liknesses of Drs. James L. Brown and Wm. J. Macneven.

Princeton College.—The library of this venerable College has received a large increase by the purchase of the Philological Library of Professor Frendenberg, of Berlin, containing 10,000 volumes.

New York Academy of Medicine.—At the Stated Meeting, May 15th, 1873, Dr. Charles P. Russel will read a paper "On the Mortality in the various States in the Union."

Death of Dr. J. C. Nott.—At a Stated Meeting of the New York Academy of Medicine, held April 17, 1873, the following preamble and resolutions, presented by Drs. W. C. Roberts and S. S. Purple, were adopted and ordered to be entered on the minutes:

Whereas, It has pleased God, in his own wise providence, to take from among us our late associate, Dr. Josiah C. Nott, therefore:

Resolved, That the demise of this eminent scholar and experienced practitioner, at a comparatively early age and amid active professional usefulness, is a grievous loss both to the science and the art of medicine, the Academy and the public.

Resolved, That by his literary labors, his teachings, his papers on yellow fever, his extensive and valuable ethnological researches, his surgical and gynæcological skill, and his great mechanical ingenuity, he adorned and advanced the cause and progress of American medicine.

Resolved, That we deplore, in his death, the loss of an amiable and courteous gentleman and much esteemed associate, and will cherish his memory with affectionate regret.

Resolved, That a copy of these resolutions be given to the family of the deceased, and published in the medical journals. Austin Flint, M.D., President.

Wm. T. White, M.D., Secretary.

At a Stated Reunion of the Medical Library and Journal Association of New York, held April 18, 1873, Dr. John C. Peters, President, in the Chair, the following preamble and resolutions were read and adopted:

Whereas, This Association, having learned of the death of Josiah C. Nott, M.D., a successful and honored physician both in the northern and southern sections of our country; therefore,

Resolved, That in the death of Dr. Nott we recognize the loss of one of our most devoted members; a gentleman eminent for his high integrity and his unblemished character, distinguished alike as an ethnologist, gynæcologist, and surgeon, and by his untiring zeal for the advancement of medical science.

Resolved, That as an expression of our sympathy with his afflicted family, a copy of these resolutions be transmitted to them and published in the medical journals; also entered on the minutes of this Association.

Wm. N. Blakeman, M.D.,
Benj. I. Raphael, M.D.,
Bradford S. Thompson, M.D.,
} Committee.

New York Obstetrical Society.—The officers of this Society for 1873 are as follows: *President*, Dr. Benj. F. Dawson; *Vice-President*, Dr. J. H. Pooley, jr.; *Recording Secretary*, Dr. Chas. S. Ward; *Corresponding Secretary*, Dr. E. Noeggerath; *Treasurer*, Dr. G. S. Winston; *Committee on Admissions*, Drs. E. R. Peaslee, Wm. Chamberlain, A. Jacobi; *Committee on Publication*, Drs. B. F. Dawson and Chas. S. Ward.

New York Ophthalmological Society.—The officers of this Society for 1873 are as follows: *President*, Dr. Herman Althof; *Vice-President*, Dr. E. G. Loring, jr.; *Secretary and Treasurer*, Dr. C. S. Bull; *Committee on Admissions*, Drs. J. H. Hinton, J. S. Prout, and H. C. Eno.

Errata.—Under the head of Hospital Reports: The quantity of molasses and water used in Dr. Buck's burn mixture is one pint each. For Garland's cerate read Goulard's cerate. 176th page, 18th line from top, read *none* for *nine*.

New Publications.

Clinical Lectures on Various Important Diseases, etc. By Nathan S. Davis, A.M., M.D., etc. Chicago, Ill. 1873.

Mind and Matter; or Psychological Inquiries. By Sir Benj. Brodie, Bart., D.C.L., Vice President of the Royal Society, with Notes by an American Editor. New York: W. Wood & Co. 1873.

Ozone and Antozone, their History and Nature, When, Where, Why and How is Ozone observed in the Atmosphere, etc. By Cornelius B. Fox, M.D., Edinburgh. London: J. & A. Churchill. 1873.

Handbook for the Physiological Laboratory. By Drs. E. Klein, J. Burdon-Sanderson, M. Foster, T. Lander Brunton. Edited by J. Burdon-Sanderson. Philadelphia: Lindsay & Blakiston. 1873. 2 volumes.

Original Lectures.

A CLINICAL LECTURE ON CASES

ILLUSTRATIVE OF

GASTRIC ULCER (HÆMATEMESIS),

ATTRIBUTABLE TO CIRRHOSIS OF THE LIVER, AND GENERAL SPINAL PARALYSIS.

By AUSTIN FLINT, M.D.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE, AND OF CLINICAL MEDICINE IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE.

GENTLEMEN:—The first case which I present to you to-day is that of Mrs. H., æt. 28, first admitted to the hospital, November 19th, 1872. Her family history is good. She was formerly intemperate, but has been temperate for the last two years. She has always enjoyed good health until about a year ago, when she was taken rather suddenly with vomiting of a blackish material, very much resembling coffee-grounds. She knows of no special cause which should give rise to that vomiting. She was ill for three weeks, vomiting almost constantly, but after the lapse of that time began to get better. About six months after, she had another similar attack, and she knew of no cause for her vomiting at that time. Since her second attack of vomiting her menses have been somewhat irregular, but otherwise she has been healthy. She was regular after the first attack, it seems, and the bearing of this point will be seen hereafter. Three days ago—*i. e.*, Nov. 16th,—she was again taken with vomiting, with no pain at first, but began to suffer severe pain several hours after the vomiting began. Since the attack of pain it has been constant and severe, and she has vomited all the time. Her food does not cause pain, but vomiting, and the pain is in the back and epigastric region. Her urine was normal. When admitted, she got a solution of morphia, a little stimulus, with milk and eggs by enema. Up to the 24th this patient was sustained by nourishing enema, which contained opium and stimulants according to circumstances. Her vomiting ceased, and upon the 24th, she was able to take milk by the mouth without producing vomiting. Upon the 26th she took one ounce of whiskey by the mouth without vomiting, and upon the 27th was reported well. The pain had disappeared, vomiting ceased, and her appetite had returned.

Jan. 7th, 1873, she was readmitted, suffering from violent pain and vomiting again, which had commenced four days before. The pain is now in the small of the back, to the right side, pit of stomach, and left side. When she takes anything into her stomach, and lies upon her back, she does not vomit, but vomits as soon as she lies upon her side.

She has some cough and expectoration of a thick white sputa, and this was present when she was previously in the hospital.

Upon admission this time, she vomited, every few minutes, a thick greenish matter, suffered from pain, and there was some tenderness over the pit of the stomach. She received, to allay this vomiting, hydrocyanic acid and ice.

During the 8th the vomiting and pain continued. And upon the 9th she again began to receive nourishing and stimulant injections, and they were given in the form of egg-nog ʒ ii. at each injection. During the 10th and 11th she vomited occasionally still received the nutritious injection, and upon the 12th her vomiting had ceased altogether.

From this state she began to improve, and at this time, the 16th, is still improving. This is the history of the case.

We have here, gentlemen, a train of symptoms which have recurred three or four times. They were of a very similar character at each time, and are referable to the stomach. They are so much related to the stomach that we may safely assume that whatsoever trouble exists, it doubtless is in that organ.

There is a form of functional disorder of the stomach which is characterized by phenomena not infrequently associated with hysteria, and which manifests itself by a form of persistent, obstinate vomiting. The patients under these circumstances will appear to reject everything, and so it will go on for weeks and sometimes for months, and the wonder is, how the patient can be nourished at all, and still all the parts of the body are in a very good condition. It is a functional affection, and in the treatment of such a case all remedies which may be employed are attended with disappointment so far as good results are concerned. The patient finally ceases to vomit and the case is ended. The best plan of treatment to be adopted in such cases is to bring the patient under the influence of hygienic and moral measures. There is no organic trouble present, nor will it lead to organic trouble, but it is simply one of the various forms of functional disturbances of the stomach.

We could hardly call the present case a case of that kind, for we have here well-defined vomiting of blood. There is a strong point in the history of the case against assuming that it is in any way connected with hysteria, and that is, that she has suffered from repeated attacks of vomiting of blood.

She has had hæmatemesis, and with this, pain has been a prominent symptom. There is a functional disturbance of the nerves of the stomach which we call gastralgia, and it is an important affection. The patient complains more or less of a constant pain, and sometimes of a very acute form; so much so that it takes all the powers of anodynes in some cases to secure relief. In general, it is a hard pain to endure, and usually is accompanied with mental depression. In gastralgia, however, there is no vomiting of blood.

In the case before us the introduction of anything into the stomach excites pain and vomiting. In gastralgia the introduction of food frequently alleviates the pain. We should not hesitate to say that it is not a case of functional vomiting accompanied with gastralgia. It has not the character of gastritis, and there is nothing in the history of the case from which we could infer that she has been exposed to any of the ordinary causes of gastritis.

The question here is this—Is it a case of gastric ulcer? I suppose it to be such a case, for the symptoms which are presented are diagnostic of that affection. The variety of ulcer which I suppose to exist in this case is that known as the round or perforating ulcer. This variety of ulcer is sometimes extremely small; it may be no larger than a pin's head. Sometimes a point no larger than that will open one of the arterial branches, and give rise to fatal hæmorrhage. This ulcer has a tendency to erode the tissues, and thus leads to hæmorrhage by opening vessels of less or greater size; or leads to perforation of all the coats of the stomach, giving peritonitis as the result.

Sometimes there is a complete perforation of the walls of the stomach without the production of general peritonitis, for there is a conservative provision against this. The ulcer gives rise to a circumscribed peritonitis, and this leads to adhesions of the stomach to some of the adjoining organs, or to the walls of the

abdomen, and now if the perforation is complete, the contents of the stomach do not escape into the peritoneal cavity, and the patient escapes a fatal peritonitis. These are the two great sources of danger, viz., peritonitis from perforation, and hæmorrhage.

What are the symptoms which are diagnostic of this variety of gastric ulcer?

It occurs in females much more often than in males.

It occurs usually in young women.

These two points we have illustrated in this patient. There has been considerable discussion in regard to the mode of their occurrence, but these discussions have been quite unsatisfactory. With regard to local symptoms, pain is one which is frequently present, but this symptom is not constant.

These points, viz., sex, age, and pain, when obtained together, are highly diagnostic; but they are sometimes absent in part. There are some peculiarities connected with the pain. It is referred to the epigastric region, and to a small circumscribed space usually. In this case the area within which the pain exists is rather large. The pain is described as of a somewhat peculiar character; of a "gnawing character," is a very frequent expression. In this case the patient refers the pain to the back as well as to the epigastrium. The pain is excited by the presence of food, and particularly certain kinds of food. With the use of stimulant articles of food it is ordinarily excited or aggravated, while with the use of bland articles of diet it is much less. It occurs after the ingestion of food, and while the food is *in* the stomach. If vomiting occurs and the stomach is emptied, the pain is frequently and sometimes instantly relieved. In this case the pain is not connected so clearly with the presence of food as in some cases, and this is not infrequently the case; still, when the patient vomits, she feels much better. Hæmorrhage is one of the most important diagnostic points. If we do not have the benefit of this symptom, we cannot feel that the diagnosis is positive. With that symptom present, we may read with a great deal of positiveness of the diagnosis. Not every case, however, of vomiting of blood is dependent upon the presence of a gastric ulcer. Hæmorrhage occurs occasionally from the stomach as one of those things which we cannot explain; but hæmorrhage from the mucous membrane of the stomach in this condition is not common, and when not dependent upon ulceration is usually dependent upon cirrhosis of the liver.

There is a common impression that hæmorrhage from the stomach is not infrequent as taking the place of the menstrual flow. This, however, is exceedingly rare as far as I can ascertain. There was one case exhibited in this hospital last winter in which there was a complete substitution. In this case there has been some irregularity of the menses, after the gastric disease, but not before, and there is no reason to believe that the hæmorrhage is at all vicarious.

These are the points—vomiting of blood, pain in a circumscribed region in the epigastrium, age and sex—that lead us to the conclusion that the patient has a gastric ulcer. There have been three attacks, and she has recovered from them, and enjoyed good health. There is no inconsistency in this, for it frequently occurs, particularly in those cases in which the habits of life may afford a new provocation to the return of the ulcer. In a considerable portion of cases recovery takes place when the disastrous complications which have been mentioned do not occur.

What are the therapeutical indications in such cases? Shall we begin with the prescription of remedies with the view of bringing certain substances in contact with the ulcerative surface to cause a cicatrization, as we do in the case of an ulcer upon the skin?

I do not think that much can be done in this direction. Most of the remedies will be changed very soon after their introduction into the stomach, and not much can be accomplished in that way. The first indication is to place the organ in such a condition as will render the ulcer most likely to heal. If we have to deal with an ulcer upon the surface of the body, we endeavor to keep it from contact with those substances which give irritation, and so we should treat the stomach. The alimentary supplies, however, generally pass into this receptacle, and we have here a difficulty with regard to the fulfilment of the indication.

In attempting to meet the indication, therefore, we must be guided by the tolerance of the stomach.

Opium, in some of its forms, is almost always serviceable. The aliments should be of a bland character, such as milk, eggs, and the farinaceous articles of diet.

Suppose that these produce vomiting and irritation? We must then nourish the system by enemata. This can be done for a long time if necessary; and the cases are not very infrequent where the system has been thus supported for three weeks or more. In this way, then, the stomach may be left entirely at rest, and renders it practicable to keep up a fair amount of nutrition.

The occurrence of hæmorrhage to such an extent that life is in danger makes the arrest of the hæmorrhage a matter of importance. This, I believe, can be best accomplished by the administration of pieces of ice, and the use of cold applications over the abdomen.

The next patient whom I present to-day is Mr. B——. This patient will illustrate several things, as is not uncommonly the case in hospital cases here and elsewhere. First of all, you will notice that he presents a pallid appearance; there is a little œdema under the eyes, and his face is a little puffy. There is, however, no œdema elsewhere in the body, except a very little over the lower part of the sternum, which is a most excellent place to determine the presence of slight degrees of anasarca. We can often determine the presence of very slight anasarca at this point when it cannot be found at any other point. Now this is connected with the condition known as albuminuria, and when we came to examine this man's urine, albumen was found present in abundance. The quantity of urine, however, is not lessened, and is not much below the average healthy specific gravity, 1016. A single microscopical examination has given us negative results. We have then illustrated albuminuria with slight anasarca. How much importance to attach to that fact we cannot now tell. Whether it is transient, or evidence of chronic affection of the kidney, must be determined by farther observations. Another affection which he illustrates is this: upon last Christmas Day he had a copious vomiting of blood. He says he vomited a pailful of very dark almost black blood, and clotted. Of course we must make a liberal allowance for this statement; but we may assume that he vomited a large quantity of blood, and this is the feature which the case illustrates. What is the rational explanation of this vomiting of blood? There are various conditions which may give rise to hæmorrhage from the stomach, one of which we have just been studying. There is, however, nothing in the history of this case which would point to either ulcer or cancer, which, when present, are fruitful causes of vomitings of blood, and we can, with positiveness, eliminate these causes. Sometimes hæmorrhage takes place from the stomach, and we cannot connect it with anything; but such cases are exceedingly rare as occurring without any pathological lesion

If we connect this hæmatemesis with certain points relative to the habits of the patient, connect it with what we find when we make physical exploration, we shall reach the probable conclusion that the hæmatemesis was the result of *cirrhosis* of the liver. With regard to his habits: for the last fifteen years he has been accustomed to the pretty free use of alcoholic drinks, and he has taken them in this way—before breakfast, and in the latter part of the forenoon. The point is, that he has taken his drinks upon an empty stomach, and taken them without dilution.

This is the manner to take alcoholic stimulants if it is desired to receive the greatest amount of effect from the smallest amount of spirit; and these are the conditions which lead to the production of cirrhosis.

The primary local action is upon this viscus. The spirit is very quickly absorbed in the stomach, especially when taken upon an empty stomach; is conveyed by the vessels and dispersed all through the liver; and so, as a continual dropping wears the stone, so does a continual impression, as in this instance, upon that organ, induce a low grade of inflammatory action, which leads to the development of fibroid tissue, and with that we have cirrhosis.

Now, resorting to physical exploration to determine whether cirrhosis is present or not, we find that there is scarcely any evidence of liver at all. There is no tenderness over the epigastric or hypochondriac region at the present time, and there is no dropsy. The degree of contraction which takes place in the liver in connection with cirrhosis is sometimes remarkable. A case was once shown me in this hospital in whom it was said the liver was upon the *left side*: but careful examination determined that it was an extremely contracted liver upon the right side, and a very large spleen upon the left. Taking this patient's habits into account with the physical evidence that the liver is much diminished in size, it is probable that this was a hæmatemesis depending upon cirrhosis of the liver.

We know that vomiting of blood occurs in connection with cirrhosis of the liver without dropsy, and perhaps in this case the occurrence of copious hæmorrhage might have been preventive as regards the dropsical effusions.

So much for cirrhosis and hæmatemesis.

The case will illustrate still another interesting and important affection. This patient has, first, incomplete paralysis of the upper extremities. He can exercise scarcely any pressure in his hands. He says that there is no difficulty in the lower extremities, and, as you will see, he can move his lower extremities freely in bed, placing them in any position you may desire. But, if it were true that there was no affection of the lower extremities, we should have a case of paraplegia affecting the upper limbs only; but the truth is, the patient has a certain amount of paralysis of the lower extremities, but he cannot appreciate it himself. When asked to walk, his mode of progress evidently shows that there is some defect of motion in the lower limbs that cannot be accounted for by general debility. Sensibility, as far as can be judged by feeling, seems unaffected.

The patient has, therefore, general paralysis.

This may depend upon morbid conditions in the cranium, embraced under that rather indistinct term of general cerebral paralysis.

There is usually, however, more or less impairment of the intellectual faculties associated with this, and a kind of delirium in which the patient imagines that he has been the recipient of some very great good.

We may have general paralysis as the result of a general affection of the spinal cord. There is no evidence of cerebral affection in this man: his intellect is clear, and he has no delirium; and it is therefore probable that we have to deal with a case of general spinal paralysis, induced by some morbid condition of the spinal cord. This morbid condition is especially marked at the upper portion of the cord, and it has selected those fibres which are distributed to the upper limbs. Still farther, the spinal cord is but partially affected, and that only in the motor portion.

The question now arises, What is the morbid condition that has thus affected the spinal cord, and given rise to these local manifestations? This, perhaps, is not easily answered in a positive way. This paralysis came on after the hæmatemesis: he was well up to that time, and had always been well. At that time he took to his bed, and, for the most part, has kept it ever since, but about a week after he first took his bed he noticed a defect of power in his upper extremities. It seems that this did not occur suddenly, but was rather gradual. This fact alone would exclude hæmorrhage into the cord or spinal canal, for in such a case the paralysis must have been sudden and complete. The fact that there is no pain or tenderness would probably exclude spinal meningitis or myelitis. Upon the whole, therefore, it seems to me that this paralysis is to be embraced under the head of functional, and I believe that such is the case.

With a large proportion of the instances in which we have general spinal paralysis the prognosis is favorable, unless it is associated with some general impairment of health; and in making my prognosis, I should say that the patient would recover, being governed by the simple fact that they do recover in a large proportion of cases. It would seem as if this man's health was seriously impaired, but I am inclined to think that he will recover from the paralysis as it is, and much more positively inclined shall I be, if the renal trouble proves to be a transient one. The patient has been in the hospital too short a time to determine what the prospect will be. This man will be placed upon a liberal, bland diet, and the progress of his case carefully observed.*

ON BRIGHT'S DISEASE.

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PRACTICAL MEDICINE, UNIVERSITY OF NEW YORK.

LECTURE II.

GENTLEMEN:—At my last lecture I directed your attention to the clinical history of the inflammatory form of Bright's disease. This evening I invite your attention, first, to the clinical history of the waxy or amyloid degeneration of the kidney, then to the cirrhotic, and then pass to the consideration of the treatment of the different forms of Bright's disease.

First, with regard to the waxy or amyloid kidney. This form of Bright's disease never occurs in persons who are in perfect health. It is always slow in its development, and its symptoms in the early stage are not well marked. It usually manifests itself as follows: a person who for some time has suffered from some chronic form of disease, in which there has been more or less of exhaustion attending its progress, such as

* It was subsequently ascertained that the paralysis in this case depended on an injury of the neck. The patient died, and the autopsy showed a partial dislocation of the second cervical vertebra, with fluid blood effused outside of the dura mater. The case seemed to illustrate the liability to overlook injuries of the vertebræ, from their latency as regards local subjective symptoms.

syphilis, caries, necrosis, or some form of chronic suppuration, more particularly chronic suppuration connected with diseases of the bones, notices that he is losing strength, that he has less mental and physical vigor than he is accustomed to have; unable to do the same amount of work, it may be, that he has been in the habit of doing; that there is a great increase in the quantity of his urine; that he is now obliged, perhaps, to get up and pass his urine two or three times a night, and at these times he often passes large quantities; he also notices a fulness of the abdomen that he never noticed before, and there is perhaps a sense of weight about the upper part of the abdomen—a dragging sensation; he very likely has detected a tumor in the right hypochondrium, and perhaps one in the left; he is also more than usually fatigued, and has dyspnœa after continued exertion; there is perhaps a little œdema about the ankles, especially at night; he has been noticed by his friends to be growing pale; his perspirations are of a urinous odor, but does not perspire readily; certain articles of food which have never before disagreed with him now trouble him, especially fats, and he may have occasional vomitings.

This train of symptoms coming on in a person who has been the subject of any of the forms of disease to which I have referred, leads one to suspect that the amyloid degeneration of the kidney is taking place. If upon farther examination an enlargement of the liver and spleen is found, your diagnosis is almost certain.

There are, in connection with this form of kidney disease, the same as in connection with the inflammatory form, three prominent classes of symptoms, viz., those referable to the urine, the dropsy, and to the nervous system.

The urine, as I have stated, is abundant. The patient may be passing as high as ℥ cc. in twenty-four hours, and ℥ lx. is a small quantity to be passed by a patient with amyloid kidney. The urine is light-colored, looking very much like clear water, or slightly amber color, and has a low specific gravity; sometimes as low as 1005. The urine always contains some albumen, and I have yet to see the first case where I could not find a trace, at least, and sometimes it is abundant, although as a rule it is not abundant. Upon making microscopical examination, casts are very commonly found, but they are not numerous. It will be necessary often to make two or three examinations before finding them, and when found they are usually the large hyaline casts, or finely granular casts.

In a pure case of waxy kidney you do not get granular epithelial or fatty casts, but it must be recollected, however, that we often do have the other form of casts present when we have the waxy or amyloid kidney, but in such cases there is more than simple amyloid degeneration, and the inflammatory form has been engrafted upon the waxy. The large hyaline casts and the finely granular are the casts which form the diagnostic basis. The large quantity of urine passed attracts the patient's attention; and not infrequently a person with waxy kidney will come to you with the idea that he is suffering from diabetes, and the quantity of urine passed is so large, such a rapid loss in flesh and strength, with a disinclination to exertion associated with dyspeptic symptoms, that, unless you are upon your guard, you will be led into the same error; but upon examining the urine the question is settled—there is no sugar, but there is albumen and casts, which always may be found by repeating the examination. With regard to the dropsy, it is never very marked in the form of Bright's disease. There is never the general anasarca which we see in connection with the inflammatory form; there may be slight œdema of the feet; you may have slight ascites, which probably depends more upon the changes in the liver than upon the changes in the kidney. In the inflammatory form the dropsy is a marked symptom, especially in the early stages; but if we find general anasarca in connection with waxy kidney, there is something present more than simple waxy degeneration.

With regard to the nervous system, the symptoms arising from affections of that are not so marked as in the other form.

This class of patients do not have convulsions nor coma; they usually die from exhaustion or some complication, such as diarrhœa or ascites; or, in other words, die as much from the effects of a waxy degeneration of other organs of the body as from the degeneration of the kidney. I doubt whether waxy degeneration affecting the kidney only will prove fatal.

The complications ordinarily occurring are waxy degenerations of the liver and spleen, and of the mucous membrane of the intestines. These patients rarely have pneumonia, or bronchitis, or pericarditis, or any of the acute inflammations which I referred to in connection with the inflammatory form. Hypertrophy of the heart is not present in this form, while in the inflammatory form it is always present in the latter stages. It is among the conditions we expect to find in the stage of atrophy of the inflammatory form, and in the cirrhosed kidney; but it is not so with the waxy form, for it is rarely present. It will be seen, therefore, with respect to their prominent symptoms and their complications, that these two forms of Bright's disease differ very widely. It is not very difficult to draw the line of diagnosis between the two forms, unless the waxy is complicated by the inflammatory form, and then the diagnosis can only be made by a most careful study of the history of the case.

The great cause for this form of Bright's disease is syphilis, and syphilis in its tertiary form. It is quite liable to occur in connection with long-continued suppuration, and caries of the bones. Just here is an important practical point, and that is, never allow a suppuration to continue any longer than is necessitated from the nature of the case. It is not wise to wait too long for a spontaneous opening in a case of empyema. Do not suffer too long processes of necroses, waiting for a spontaneous cure; nor wait in any other like position, in which you are liable to have an amyloid degeneration of the kidneys or other organs occurring. A too long-continued empyema may give, as a result, an amyloid kidney, which will very much complicate the case, and be the element of a fatal termination. These are the principal points in the clinical history of the amyloid kidney, and you probably will not be able to recognize it in the first stage; but its second and third stages are generally easily recognized. You may not be able to reach a diagnosis by an examination of the urine, for very many of the same elements are to be found in it as in the atrophied stage of the inflammatory and of the cirrhotic kidney; but taken in connection with a careful study of the history of the case, a positive diagnosis can generally be reached. As regards the cirrhotic form of kidney, it is well to notice that it develops very insidiously. In the early stage there is nothing to indicate its existence. There may be no albumen or casts in the urine, no dropsy, and none of the symptoms which usually mark the presence of the kidney disease, yet at the post-mortem examination kidneys may be found which present very marked changes, and which I described under the head of cirrhosis of the kidney.

Generally, however, this form of Bright's disease is marked quite early by the changes which take place in the nervous system. I remember two cases in which the first thing that attracted the patient's attention was a dimness of vision. The particular thing for which I was consulted was the pain in the head and loss of sight. Generally, however, this class of patients, at first, will complain of dyspepsia. They, too, find that they are not able to work as they have been accustomed to.

They notice that they are passing more than their normal quantity of urine; occasionally the feet and ankles are swollen, particularly after standing or walking for some time; this œdema comes and goes, is most marked at night on retiring—disappearing in the morning on rising. Their complexion assumes a dingy hue. Their countenance has an old, care-worn expression. They are constantly looking forward to a time when they can rest from their ordinary hard labor. This class of patients not unfrequently consult their physician, who prescribes for the relief of their dyspeptic symptoms, with the assurance that they will be all right as soon as they can leave off work and take a rest; and suddenly, when excited by something which elevates them beyond their normal limit, they are seized with convulsions, go into coma, remain in an insensible condition for twenty-four hours, and die. The urine perhaps had been examined the day preceding the convulsion, and no albumen was found, but now it will be found to contain albumen, and perhaps casts.

The chief features with regard to the urine in this form of Bright's disease is the large amount passed, normal color, low specific gravity, fitful presence of albumen, and the casts are mostly long, hyaline and finely granular. I stated that in the waxy form albumen is always present, and the inflammatory form rarely without it in any stage.

The dropsy in this form is never a very urgent symptom. In the latter stages of the disease there may be dropsy of the lower extremities, associated with dropsy of the abdomen, for cirrhosis of the liver is very likely to be associated with cirrhotic kidney. The nervous symptoms are the most prominent symptoms in this form of Bright's disease, and they come and go in a way which is not easily explained. Their mode of production is essentially the same as in the other forms. The most frequent and prominent is headache.

There are no such nervous symptoms present in the amyloid degeneration as are seen in connection with this form. Oftentimes the patient will be delirious, and there have been cases of acute mania dependent upon this form of Bright's disease. Patients are not only nervous and irritable who suffer from this form of Bright's disease, but are likely to have convulsions without any engrafting of the acute inflammatory form upon it. Amaurosis is a form of nervous affection which is frequently met with in this form of degeneration. It occurs most generally quite late in the disease, and is due to neuro-retinitis.

Sometimes we are able to recognize the kidney change by the existence of the neuro-retinitis, when no other symptoms exist. Amaurosis occurs in this and in the latter stage of the atrophied form, as a true neuro-retinitis, while it occurs in the other forms independent of it. It occurs therefore as a real symptom, and as a complication. With regard to the causes of this form of Bright's disease, the most common undoubtedly are gout and rheumatism.

It is what is called the gouty or rheumatic kidney. It occurs also as the result of the steady use of alcohol. It is not the occasional drinking that gives rise to the cirrhosis of the liver, nor is it the occasional drinking that will produce cirrhosis of the kidney, and we are liable to have the two occurring together as the result of long-continued steady use of alcoholic drinks. Garrod mentions that he has frequently met with this condition of the kidney in connection with lead-poisoning. It is not the cirrhotic disease which occurs in connection with chronic heart disease; that change in the kidneys is simply the result of the interference with the capillary circulation of the organ, and the same kind of hardening is seen in the liver and spleen, and dependent upon the same cause. Increased connective tissue does not mark that form of hardening, but there is simply a change in the blood-vessels of the organs. The complications of this form are, first, hypertrophy of the heart, the same as in the last stage of the inflammatory form. The patients are also liable to suffer very much from slight exposures to cold, have bronchitis, not infrequently pneumonia, and inflammations of the serous membranes the same as in the inflammatory form. It is difficult, without a history of the case, to draw a line between the cirrhotic form and the atrophied stage of the acute inflammatory form. The complications and the symptoms are very much the same, but the albumen is not as constant in the cirrhotic form as in the others. The slow development of the disease, and the diathesis of the patient, in contradistinction to an acute history, will help you to reach a diagnosis of this form of Bright's disease.

This is a summary of the symptoms of Bright's disease as it is seen in its three forms. I have given you the striking points only, and must pass on, leaving you to fill up the minor considerations.

We next come to that which most interests our patients, viz., the question of treatment.

The usual form of question with which the patient will meet you is, "You cannot cure Bright's disease, can you, doctor?" In the light of my experience I am able to answer them affirmatively, and I tell them that I can.

I do not pretend that we can cure all forms of Bright's disease, or a majority of the cases that come under our observation; but there are certain classes of cases that we can cure, or at least can help them to get well. It is not too much to say that all cases can be benefited, relieved of their distressing symptoms, have their lives prolonged, and placed in a sufficiently healthful condition that, perhaps, for several years, they may be useful members of society. I do not look upon Bright's disease as being absolutely incurable, yet we should never expect to cure the patient who has the cirrhotic kidney or the waxy kidney, or the atrophied stage of the inflammatory form, but these can receive much benefit, and more benefit sometimes than some other forms of the disease. I shall only make mention of some of the plans of treatment which have been proposed, and then speak briefly of those means which I have found the most serviceable.

The first mode of treatment that was adopted in this disease, when it was regarded as an albuminous nephritis, was general and local bleeding, but this was soon found to be attended with bad results, and mercurials were resorted to with the idea of putting the system under its constitutional effects, and keeping it up for months: this also was abandoned for a like reason. As soon as the pathology of the disease was better understood, an entirely different mode was adopted, based upon pathological changes which take place in different stages of the disease. The mode of reasoning was,—we have an inflamed organ to deal with, and the only way to cure an inflamed organ is to give it rest; that it should be treated upon the same general

principles as an inflamed eye or an inflamed leg would be treated, and the first great principle to be adopted was to give the organs rest.

The plan of treatment, therefore, was to make the skin supplement as much as possible the work of the kidneys, and this was called the diaphoretic plan of treatment. This soon received an important adjuvant in the use of hydragogue cathartics; and these two agencies, diaphoretics and hydragogue cathartics, were the chief agents employed for the elimination of the urea from the system. A leading feature in carrying out the diaphoretic plan was the use of hot-air baths. I have seen many a patient go through this plan of treatment in the hospital, and the result is this: after they have received three or four hot-air baths, assisted by hydragogue cathartics, the œdema begins to disappear, and the general symptoms will be relieved very much, but the trouble is they do not remain relieved. After a short time these patients grow anæmic, lose their strength; the dropsy disappears, it is true, but the complaint is, "I am terrible weak;" and as this process goes on we reach a point beyond which we no longer can relieve the dropsy, and sometimes patients have gone into convulsions while taking the hot-air bath. The use of diuretics was forbidden, or if used at all, they were to be used very sparingly. The theory was that the kidneys must rest; an inflamed kidney should not be stimulated.

Several years ago I became impressed that this diaphoretic plan of treatment was wrong, for it rapidly depleted patients that could not bear depletion. For the same reason I have objected to the use of hydragogue cathartics, not that I discard them entirely, but I simply hold them as reserves, for they do not enter prominently into my plan of treatment. In the study of a plan of treatment let us ask ourselves the simple question, What do we wish to accomplish in the inflammatory form of the disease? We wish to eliminate the urea, and remove the obstruction which exists in the tubes of the kidneys. We also wish to obviate the effects of the urea upon the nervous system. How are these indications to be met, and what are we to use to accomplish the desired purposes mentioned? The first step in the process is to remove the exudation which is in the tubules of the kidneys; for it not only prevents the elimination of the urea by preventing the kidneys from performing their proper amount of work, but if it remains in the tubules it develops a degenerative inflammation.

In treating a case of bronchitis, we would not place an obstruction in the bronchial tubes and prevent the expectoration, but we would aid, in all possible ways, free and unobstructed expectoration.

The same condition of affairs obtains in Bright's disease, and the exudative material so obstructs the urinary tubules as to prevent the organs from performing their proper functions. If by prompting the kidneys to increased secretion they can be made to pour out fluid enough to wash out this material which obstructs free passage for the urine, we have accomplished an important end in the management of the case.

To accomplish this I recommend a remedy which will increase the urinary secretion without stimulating the kidneys. That remedy is digitalis. I am convinced that it does not act as a stimulating diuretic, but that it acts upon the local circulation of the kidney. Clinically, digitalis acts as a diuretic without stimulating the kidneys. Inducing an increased flow of urine in this way we rid the system of its urea much more completely than we can by the skin or bowels, for these are both unnatural ways of eliminating it.

One word with regard to digitalis. We have for many years been taught to believe that while administering this drug we must guard against its "cumulative effect," so called. All this I have come to disregard; for I have repeatedly administered half-ounce doses of the infusion every two hours for 48 hours, and have never seen any unpleasant effects from thus using it. If any benefit is to be received from this drug in this disease, it *must* be administered in large doses. The dose which I usually recommend is ℥ss of the infusion, and in the acute stage of Bright's disease it may be given every two hours for 24 hours, and then wait a little and watch its effects. If the diuretic effects are not satisfactory, they may be increased by the addition of bitartrate of potassa. Its administration in more moderate doses, say ℥j three times a day, must be continued for weeks. In those cases in which the exudative matter filling the tubes is the result of a catarrhal inflammation of the tubes, if it can be washed out, nature forms new epithelium for the repair of the tubes, unless the stimulants which have produced the increased secretion of urine are continued. Hence the necessity of watching the effect of the remedy. The external application of dry cups over the kidneys, and following them with poultices, are of service. The digitalis leaves may be used for a poultice after the dry cupping, and thus applied, they will increase the diuretic effect of the drug administered internally. After the use of the dry cups, and the congestion and hyperæmia to some extent are relieved, if your anæmic symptoms are still urgent, you may resort to hot-air baths and hydragogue cathartics. This makes the principles for the accomplishment of the first proposition in the management of acute Bright's disease.

And now let us consider the effect of the urea. This is the element that produces the convulsions; perhaps the patient has already had one or more when you are called to see him. What are the means that we have for controlling the effects of urea upon the nervous system? I believe that opium is, of all drugs, the best. If called to see a patient who has already had a convulsion, or is having symptoms of convulsions, I should not hesitate to throw into his arm 10, 15, or 20 drops of Magendie's solution of morphine by the use of the hypodermic syringe. It will not kill him; but, upon the other hand, I have seen it many times produce a calm, quiet sleep, profuse perspiration, increase the flow of urine, and within a few hours the patient awake to consciousness as the result. As regards the amount that may be used in this condition, I am not prepared just now to limit, especially after the experience I have had this afternoon.

I was called in consultation about 5 P.M. to see a patient whom I had seen about a year before, when the diagnosis was waxy kidney. At this time he is probably suffering from an acute attack of the inflammatory form engrafted upon it, the result of a wetting. He had been seized with convulsions, and when his attending physician saw him first he had had several, and he gave him a hypodermic injection of 20 drops of Magendie's solution.

The effect was to materially quiet the patient; but again showing some symptoms of returning convulsions, he received another injection of twenty drops, and in this he was watched, receiving fifteen or twenty drop injections, upon the least return of symptoms indicating convulsions, until he had received eighty-five drops administered in this manner. That man had remained unconscious from the time of his seizure, all through the day; but when I saw him at the hour indicated, he awoke and called me by name, although I had not seen him for nearly a year previous to this visit. This is not

the only instance I could cite you to, where the patient was supposed to be dying from the influence of urea, who were saved, as I believe, from immediate death by the use of morphine.

As regards the treatment of the second stage of Bright's disease of the inflammatory form, where the fatty degeneration has taken place, the same forms of treatment are indicated.

The indications are the same, and the same treatment, as far as diuretics are concerned, is to be instituted; but here we wish something in addition. The acute symptoms are passed, and the anæmia begins to show itself. You would commence the treatment of these cases by the use of iron, tonics, fresh air, best hygiene possible, and do not let them take stimulants as they are ordinarily taken, such as whiskey and brandy; but they may take certain forms of wine. The best wines to be given in this condition are our native wines and the light French and German wines, and these patients improve by allowing a little wine at dinner. All the time the secretion from the kidneys must be watched, with regard to its quantity, density, kind of casts, etc., and I have little doubt but that a certain proportion of cases may be saved even in the stage of fatty degeneration. If the patient is cured in this stage, it must take place before that molecular absorption occurs which leads to the destruction of the tubes, and announces the beginning of the stage of atrophy. In the last stage, or stage of atrophy of the inflammatory form, considerable benefit may perhaps be derived from a change to a warm climate, keeping the surface of the body well covered, free from exposure, and making life as comfortable as possible.

The urine again should be watched carefully, and if found to be a little scanty, order the patient to take a dose or two of digitalis, and in that way the patient will get along very well. He will also receive much benefit from the use of tonics and cod-liver oil, and the general plan of treatment consists in watching the patient as regards the anæmia, quantity and character of urine, and introducing remedies according to the indications.

As regards the waxy kidney, nothing can be done as far as cure is concerned, and it must be treated upon the same principles as you would treat waxy conditions elsewhere in the body.

If dependent upon syphilis, the treatment of the syphilis is to be the leading feature in the curative plan; if dependent upon chronic suppuration, remove the cause if possible, and in general the patient will receive all the benefit that he can receive from the use of tonics and hygienic measures, and these may accomplish something. In syphilitic cases I generally use Blanchard's pills, one t. i. d., and in many cases with considerable benefit. These patients may take a moderate amount of stimulus; must be kept well protected, and receive the best of care.

Under these circumstances they will get along very comfortably, and yet they find that they are all the while in danger of diarrhœa, suffer from headaches, etc. If the inflammatory form becomes engrafted upon this form it must be treated in the same manner as the uncomplicated inflammatory form.

In the case of the cirrhotic kidney curative treatment is also useless. The patient will receive scarcely any benefit from anything except tonics.

The administration of diuretics is hardly ever resorted to unless there is a complication by the occurrence of an inflammatory attack. This form of the disease is occasionally benefited by the administration of a hydragogue cathartic, where there is a distention of the abdomen. If the disease exists in connection with gout or rheumatism, the treatment for these diseases will be adopted. If the patient is anæmic, that condition must be treated, and in general, as I have said, tonics constitute the chief agents to be relied upon. Of all the tonics, I prefer strychnia. Iron may also be used, but strychnia and iron do much better than iron alone.

Thus, gentlemen, I have passed over some of the most prominent points in the pathology, clinical history, and treatment of the different forms of Bright's disease. I have only endeavored to set before you the prominent features of the disease, and must leave the interesting details of pathological, clinical, and therapeutical study to your own careful observations.

Original Communications.

URETHROTOMY:

INTERNAL INCISION COMBINED WITH EXTERNAL OR PERINEAL SECTION.

By F. N. OTIS, M.D.,

CLINICAL PROFESSOR OF GENITO-URINARY DISEASES, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

SINCE the attention of the profession has been drawn to the value of the internal incision and divulsion of urethral strictures, by the plans and instruments of Maisonneuve, Thompson, Holt, Gouley, and especially since Maisonneuve's filiform, Gouley's fine whalebone guide, and my own dilating catheter, have been in use, few indeed are the strictures that cannot be successfully treated by gradual dilatation, by internal incision, or by divulsion. Occasional cases present, however, where, from the tortuous course or from the extreme tenuity of certain strictures, or from these causes combined, even the most ingenious, delicate, and skilfully adapted instruments cannot be passed through them into the bladder.

In such cases an external section of the stricture becomes an acknowledged and absolute necessity. The usual plan of operation,—when the external section of a stricture has been decided upon,—does not differ materially in the practice of skilful surgeons. Briefly, it is to cut down upon the sound or other instrument which has been previously introduced, through, or down, to the point of stricture, and then to *incise freely all stricture tissue*, until an instrument, sound, or catheter of the normal dimensions of the urethra can be readily passed through the urethra into the bladder. I have now to propose a modification of this plan of operation, which, from the fact that it aims to make the external perineal incision in great measure subsidiary to the operation of internal urethrotomy, or divulsion, may be found in certain cases to lessen the difficulties of the *perineal section without a guide*, and also to lessen the extent of the integumentary cicatrix, which may be held answerable to some degree for the usual subsequent reëntraction at the strictured point. The preliminary steps in the proposed operation are as if the ordinary external section were contemplated. An incision is made down upon the anterior face of the stricture, but aiming to enter the urethra by as small an opening as possible, and through this, as a new point of departure, endeavor to introduce a fine soft filiform or whalebone guide through the stricture. If the effort prove successful, when the main body of stricture is between the incision and the bladder, then to pass the opposite end

of the guide through the anterior portion of the urethra, screw on the shaft of a Maisonneuve, pass it down into the bladder, and operate by passing the blade down through the *superior* wall of the stricture, and thus into the bladder. If, on the contrary, the stricture has been exposed on its distal aspect, the mode of exploration is to be reversed, and on success in permeating it the internal operation performed in the same manner. In case of failure to pass the guide through the stricture by the incision, this is extended little by little, interrupted by frequent attempts to pass the stricture with the filiform or whalebone guide, until the stricture is just sufficiently incised to permit its easy transit. The following cases, extracted in full from the records of the Genito-Urinary Department of the Stranger's Hospital, will serve to illustrate the proposed method of procedure.

Case I.—*Organic Stricture of the Urethra.*—Service of Dr Otis, Stranger's Hospital. George H., æt. 44, married, Germany. Admitted March 19, 1872. Patient has been a perfectly well man up till 14 years ago. At that time he contracted gonorrhœa, which became chronic, and was in time associated with the symptoms of stricture of the urethra. For this he entered the New York Hospital, where he was treated by the method of gradual dilatation. Having learned to pass a No. 8 bougie on himself, he left the hospital, entirely relieved of his symptoms, and continued to do well for a number of years, passing from time to time an instrument as he was directed. On one occasion (about 5 years ago) he had some difficulty in introducing the bougie, and from that time abandoned its use. Soon, however, the old symptoms returned; micturition became painful, the stream grew smaller and smaller, and of late urine is voided by drops.

In addition to this trouble, patient has, during the past few years, suffered considerably from intermittent fever, during the attacks of which the difficulty of passing water has been extreme.

On admission:—Patient presents a well-marked malarial cachexia. No organic visceral lesions found. The urethra presents a very tight stricture about five inches from meatus. Urine is passed guttatim, or in a series of very small streams. An attempt made by Dr. Otis to enter the bladder with a fine whalebone bougie failed.

March 22.—Patient etherized and another attempt made, but with the same result.

March 23.—Had an attack of fever during the night. Ord. quin. sulph. gr. v. t. i. d.

March 28.—Again etherized and another attempt made with whalebone-guide bougies, some of them twisted at the end. Present, Drs. Markoe, Sands, Sabine, Weir, and others.

After a thorough and prolonged trial this procedure was discarded, and the patient put in position for lithotomy. A probe-pointed silver catheter having been passed down to the stricture, a small incision was made in the perineum down to the probe. This exposed the urethra for the distance of *a quarter of an inch* just at the beginning of the stricture, and this point was secured by two silk threads passed through the mucous membrane on either side of the incision. From this opening in the perineum efforts were now made to enter the bladder, which after a while, and not without difficulty, proved successful. A small filiform first entered, and the passage then enlarged by different dilating catheters (probe-pointed) up to No. 3 (1 mm. in diam.) This having been accomplished, a probe-pointed director was introduced into the bladder through the perineal opening, and the staff of Maisonneuve's urethrotome passed through the penis down to the stricture, then pushed onward to meet the director, and finally slipped along the latter into the bladder. The two blades of the instrument were *passed in succession* down through the stricture, dividing it superiorly. A large (No. 12) silver catheter was then introduced to be retained, cold-water dressing applied to the wound, and the operation was completed.

March 28, 6 P.M.—Patient rallied well from the ether. Ord. quin. sulph. gr. x. statim, and again at 9 P.M., together with suppositories of morphine (¼ gr.) p. r. n.

March 29.—No fever since operation; water passing freely from the catheter.

April 1.—Catheter removed. Some pain in chest. Ord. sinapism and dry cups to the chest. Slight constitutional disturbance.

April 2.—No fever. Wound doing well. Lateral decubitus directed. Ord. quiniæ sulph. gr. ij., t. i. d.

April 3.—Comfortable. Urine flowing less freely since change of position.

April 4.—Restless from pain in the wound. No. 8 sound passed. Sits up.

April 6.—No. 8 passed again.

April 8.—Patient able to walk about.

April 12.—Nos. 8, 9, and 10 sounds passed. Wound closing. Exuberant granulations touched with argenti nitr.

April 14.—No. 10 sound passed again.

April 16.—No water passed through the fistula for the first time to-day.

April 23.—Fistula healed.

April 24.—Patient went out on a pass and did not return. Discharged.

Case II.—*Organic Strictures with Perineal Fistulæ.* B. G. W., 44, New York. Married. Carpenter. Admitted April 25, 1872. Patient had one attack of gonorrhœa eighteen years ago, followed by a stricture which gave him no trouble until eight years since, when he fell some eight or ten feet astride some floor timbers, and "felt something give way." Experienced great pain and smarting when urinating, with soreness in the urethra. Urine contained pus, and on two occasions noticed blood in it; from this time the stricture became smaller. Two years after the accident an abscess formed in the scrotum on the anterior portion and right side of the median line which broke and discharged pus and urine; in about three weeks it healed, but reappeared. Last winter first had an attack of retention of urine, which was relieved by the catheter. A week or two afterwards another abscess formed at the junction of the perineum and scrotum on the left side of the median line, which also discharged urine and pus; this has never healed.

Two years ago commenced to take morphine by the advice of a physician, and has continued its habitual use ever since; states that he is accustomed to divide a drachm bottle of morph. sulph. into six parts, and take one of them daily, one-half in the forenoon and the remainder in the afternoon. On admission patient pale and unhealthy looking; complains of great pain and smarting during micturition; passes most of urine through fistulæ; has hypospadias; two fistulæ mark the location of the former abscesses; palpable induration throughout most of scrotum.

April 26.—Meatus incised by Civiale's instrument; bladder cannot be entered by the finest filiform bougie, but a very fine whalebone bougie passed in; stop morphine and substitute tr. hyoscyami ʒi. every hour until easier.

April 28.—No morphine to-day; guide bougie again

passed; slept only after repeated doses of tr. hyoscyamus.

April 29.—Very tremulous; "has hot flashes all over;" nervous system much relaxed; order strong coffee, Oj., and ¼ gr. morph.; appetite better; reports more difficulty in passing water.

April 30.—Sleepless from want of morphine; passed water guttatim mainly through urethra; repeat coffee and ¼ gr. morphine.

May 2.—Crying for morphine; nervous system less relaxed; slept a little after repeated doses of chloral hydrate and bromid. potass.

May 3.—This morning has convulsive startings; is in great distress for morphine; gr. i. administered with great relief; an attempt to pass an instrument was made, with the intention to operate, but as nothing larger than the whalebone guide bougie would pass, the operation was postponed; ¼ gr. morph. given.

May 9.—Comfortable on ¼ gr. morph. daily; since last date no urine has passed through the ant. fistula, and only a little pus; passes urine equally through posterior fistula and urethra; considerable pus and ropy mucus in vessel.

May 11.—Takes about ℥ vi. whiskey daily.

May 13.—Operated on by Dr. Otis. Present Drs. Willard Parker, G. A. Peters, Curtis, Dr. Bond, of Keokuk, and others. A fine whalebone guide bougie ½ millimetre in diameter was introduced into the bladder, and over it a small dilating catheter passed down the urethra to the anterior stricture (about 4 inches from the meatus), which was so small as to arrest its further progress. After several fruitless attempts to pass Gouley's and other instruments, patient was etherized and put in position for lithotomy. Perineal section was then performed, the whalebone bougie acting as a guide; several vessels tied and twisted; bladder was entered by a No. 11 bougie, which was retained there during the rest of the operation. Dr. Otis' dilating catheter was then passed from the incision through a long, close stricture to the meatus, followed by the larger size, and an attempt made to follow it up with the staff of Maisonneuve's instrument, which would not run upon the whalebone. A filiform bougie was then passed from the meatus alongside the whalebone, the point emerging at the incision in the perinæum, the staff of Maisonneuve's instrument screwed on and passed down, the blade being pushed through the stricture, which yielded slowly and with so much difficulty that the handle of the blade was twice bent at a right angle before the stricture was divided. The extent of the stricture was three inches; to further dilate the urethra Voillemier's rupture instrument was used; this was followed by considerable hemorrhage, promptly checked, however, by a No. 11 French bougie passed from the meatus and emerging at the wound in the perinæum. Operation lasted about two hours; patient put to bed, ¼ gr. morph. in suppository, and quinine gr. v. given; cold application to penis and poultice to abdomen. At 8:45 P.M., after urinating, patient had a chill; T. 102.2°, P. 118, R. 28; bougie removed; whiskey ℥ ss. and morph. sulph. ¼ gr. administered, and heat to feet. 11 P. M., temp. rising, and ¼ gr. morph. p. r. n.

May 22.—Rested some after 2 A.M.; feels comfortable; water passing freely through the incision.

May 23.—Some pain in scrotum and perinæum; bowels opened.

May 24.—Some chilliness during the forenoon; some water passing through urethra; considerable constitutional disturbance; inflammatory œdema in scrotum; relieved by poultices and suspensory bandages, and quinine gr. v. q. 4 hr., and morph. p. r. n.

May 25.—Scrotum about the same; water passes through penis and incision; some diarrhœa; liq. opii comp. substituted for morphine.

May 29.—No. 6 French bougie passed into bladder, followed by No. 10; œdema in scrotum subsiding; continued quinine and morphine.

June 1.—No. 10 bougie passed again; patient comfortable.

June 2.—Patient up and about; takes from 1½ to 2 grs. morphine daily.

June 4.—No. 11 bougie passed easily into bladder.

June 5.—Almost all the urine passes through penis.

June 6.—No. 12 steel sound passed; patient taught to pass the sound, and on the 18th discharged cured.

NEW YORK, March 26, 1873.

Reports of Hospitals.

CHARITY HOSPITAL, N. Y.

NOTES OF TREATMENT AND PECULIARITIES IN PRACTICE.

FROST-BITE.

THERE was one case of frost-bite which involved the phalanges of both feet. They were being dressed with carbolic applications, waiting for spontaneous amputation to proceed a little further, when the bones would be removed, and the stump allowed to heal by granulation, perhaps assisted by the *grafting* process.

ULCERS.

We were present on one of the days which may be called a "field day" in the ulcer ward.

A general principle of treatment adopted in every case, with a single exception, that day, was that of strapping with adhesive plaster and using a firm roller bandage. Each ulcer was snugly strapped with either transverse or basket strapping, and the limb firmly bandaged.

The dressing for the ulcers was varied according to the requirements of each case, certain appearances indicating the use of certain applications. Some experience is requisite to recognize the exact condition requiring the use of a certain remedy which, if properly applied—applied in strict conformity to the indication—renders the general treatment much more satisfactory.

Examples of specific ulcers are somewhat numerous here. One was dressed with iodoform and glycerine (sat. sol.) before applying the straps. It required a little stimulating.

For all these cases of gangrenous and sloughing ulcers either a saturated solution of carbolic acid is used, or a solution of bromine, grs. xvi. to the ounce of water.

The bromine is the more common application, and it most admirably rids the surface of that sloughy, nasty condition invariably present in such cases.

Traumatic ulcers generally receive the extra attention of scraping epidermal scales from the leg with a pocket-knife and spreading them over the surface of the ulcer. Since this has been practised, the ulcer has healed much more rapidly than before, with no different treatment otherwise. Over these scales was placed a dressing of balsam of Peru, and over this the straps and bandage as usual. Covering the surface of the ulcer with a coating of balsam of Peru is the ordinary method of dressing all ulcers that require no special application, and it is quite generally

used in connection with the special application. For example, balsam of Peru and iodoform (in powder) act together better than either alone. One is soothing and the other stimulating, and the joint benefit received from the combination is much greater than that received from either alone. When ulcers are covered with exuberant granulation, the solid stick of nitrate of silver is applied, and over this the ordinary dressing.

Ulcers with thickened edges are reduced by freely cutting through the indurated mass in transverse incisions throughout the entire circumference of the ulcer.

The treatment of varicose ulcers forms no exception to the general rule.

A man who had both legs covered with ulcers, from half an inch to an inch in diameter, resulting from hard service and low salt diet at sea, received the iodoform dressing, the ulcers being neither strapped nor bandaged.

An old man in bed with an ulcer involving about two-thirds of the circumference of his leg, which had been in an extremely sluggish condition, now exhibits a lively growth of healthy looking granulations all over its surface, which had been established within three or four days by the use of the following:

℞	Flour	℥ iv.
	Gum tragacanth	℥ ss.
	Gum arabic	℥ j.
	Egg, No.	i.
	Chalk	ʒ iij.

Make a paste by adding boiling water, and while fresh place it on the ulcer with a brush, four times a day. When the material sours it must be changed.

One great advantage derived from this general plan of treatment by strapping and bandaging is, that the patient can go about without detriment to the ulcer.

SPRAINS.

Some of these cases are treated by the application of a roller-bandage firmly applied; some particularly old cases, by a local wash of arnica, and some by the use of the immovable apparatus, and that usually employed here is the starch bandage. Rest is a great desideratum, and if the rest which the patient can give to the limb by simply being in a hospital is seconded by the local application of arnica, a marked improvement is soon seen.

BURNS.

The chief agents employed in the treatment of this class of difficulties in this hospital, are the carbolic salve and Carron oil.

℞	Lime water	℥ viij.
	Flaxseed oil	vij.

In some cases a little turpentine is added to the Carron oil.

CHRONIC SYNOVITIS.

The application of Sayre's splint is a very common method of treatment.

This splint and the advantages derived from its use are too well known to the profession to require any special description or comment.

One case was doing exceedingly well under the influence of the sponge treatment, which consists in binding wet sponges about the joints (in this case the knee-joint) and renewing their application every day. Wet the sponges in hot water.

Progress of Medical Science.

THE MAGNESITE DRESSING.—Kuester, of Berlin, has employed this form of dressing for two years, and believes that in many cases it is superior to plaster of Paris. Magnesite is easily procured, as it is extensively employed by the manufacturers of artificial carbonic acid waters. It consists, in fact, of the neutral carbonate of magnesia, from which free carbonic acid is readily obtained by the addition of any strong acid. To one part of magnesite he adds three parts of soluble glass, which is composed of the silicate of soda and potash. Both are then mixed into a thin paste. The silicic acid unites with the magnesia, and carbonate of potash and soda are separated.

It is used in about the same way as the ordinary plaster of Paris dressing. The author usually first protects the part with flannel, and then takes linen bandages, soaks them thoroughly in the paste and applies them firmly. Two, or at most three, layers are all that are requisite. The parts must then be kept immovable from 24 to 36 hours, and the dressing will become as hard and unyielding as stone. Lightness, cheapness, and greater durability are some of the most prominent advantages claimed for this method. The author believes that it is far superior to plaster of Paris in certain cases, as in the treatment of chronic inflammations of the shoulder, knee, and ankle joints, in contractures of the knee, and in imperfectly united fracture of the femur.—*Deutsche Klin.*, 12, 1873.

MICROCOCCI AND THEIR RELATION TO THE CAUSE OF DISEASE.—Professor Klebs, of Wurtzburg, has recently made some very valuable contributions to this subject, which has attracted so much attention during the last few years. Both he and Recklinghausen, and afterwards Waldeyer and many others, have demonstrated Bacteria and Micrococci in the so-called pyæmic affections. While these observers have been chiefly occupied with these organisms in metastatic abscesses, he has forced them, step by step, from the diseased surface into the substance of the tissues, and concludes that they are developed and increased before the collections of pus are formed. In the year 1871 he was convinced, from the reports on the Rinderpest and Smallpox, that these bodies were unlike the normal constituents of the body, and in each one of the diseases had a peculiar distribution and arrangement. The question for solution thus was, whether these bodies were normally present in the body, and whether they are to be regarded as parasitic organisms. The first question has been satisfactorily answered by careful examination of the blood. To determine the second and more important one required, first, the absolute demonstrations of these bodies, and secondly, some way of cultivating them, by which this development should be favored, all impure matters excluded, and the process followed under a high magnifying power. To accomplish this object he employed a method which he calls fractional culture. Taking the diseased organ he pressed out the fluids, and filtered them, by means of Bunsen's air-pump. The residue was then washed with distilled water until all of the soluble portions were removed. It now consisted almost entirely of Micrococci, with only a few elements of the tissues, such as nuclei and elastic fibres. Of this a very small portion was removed by means of a capillary tube and placed to a 2 per cent. solution of the acetate of ammonia, which was boiled and put away in a stoppered bottle.

After the development of the micrococci was completed, a small portion was placed in a second bottle, and of this still other portions were placed in a third and fourth bottle. By this means it was intended to eliminate those substances which were only present in small quantity in the first fluid, and this was shown by microscopic examination to be the case.

The second requirement was filled by placing the cultivated germs in microscopical glass chambers, which were then hermetically closed. To promote the process of cultivation, gelatine was previously placed in the chambers. It fixes the little particles in and on itself, and exposes them to view for a long time. The most valuable result of this experiment was, that the micrococci which were found in the different diseases showed different and characteristic methods of development, and that, accordingly, a specific disease may be due to specifically different organisms.

The artificial production of any of these diseases has only been successful in the case of the septic micrococci. The following description is given of changes which these bodies exhibit during their development:

1. The septic micrococcus first forms balls of granules on the layer of gelatine, where it is exposed to the air; then the greater number form colonies of bacteria and a lesser number are converted into contractile plasmic balls of a yellow color. The gelatine apparently undergoes no change. If the air is withdrawn, the development very soon stops, the contractile bodies are not formed, and the balls of granules assume a uniform brown color.

2. The diphtheritic micrococcus forms brown balls of granules at once, and they constitute large cohesive conglomerates if gelatine be present in large quantity. Smaller portions then separate from these masses, and grow to the size of the red blood corpuscles; at first they are homogeneous, but at length become granular, just as the first do. Finally the whole mass breaks up into free granules and very active little bacteria, and the gelatine becomes entirely fluid.

3. The micrococcus of measles was taken from the trachea and the blood in the heart of children. The blood was taken up in flat capillary tubes and commenced to develop balls of micrococci out of unseen elements. First of all there appeared pale collections of micrococci in the glass chambers, and they rapidly changed into active bacteria. These latter migrated rapidly to the periphery, where they formed a narrow closed zone which can only be compared with a band of little rods. From these new collections of moving bacteria originated, but their subsequent relations could not be observed, as they did not seem to maintain any regular order.

4. Vaccine virus was next examined in a similar way. The elements in this case arranged themselves like the sarcinæ, in fours. Their size was hardly greater than the ordinary micrococci.

Prof. Klebs believes that these facts will suffice at present to give a real scientific basis to the theory, that the infectious diseases possess specific germs which are endowed with vital capacities of their own.

Wounds of the External Genital Organs.—Two interesting cases of wounds of the external genital organs, in females, are mentioned by Dr. T. Parvin, of Indianapolis, Ind. (*Am. Practitioner.*) As to the treatment of these wounds, he says that it is usually a fruitless waste of time to hunt, as advised by some of the old authorities, bleeding vessels for ligation or torsion, an unwise thing to empty out clots, a needless thing to rely on astringents or sutures; but a graduated compress and bandage are the simplest and most effective means in the vast majority of cases. The bladder should be emptied by the catheter twice in the twenty-four hours; and in any case where the hemorrhage has been severe, the patient should not be allowed to sit up within forty-eight hours, even for a few minutes.

The Employment of Pessaries.—John Lambert, M.D., Salem, N. Y. (*Journ. Gynæcological Soc.*), in a communication on "Uterine Displacements," says that the use of pessaries in these cases complicates treatment and hazards successful results. In a certain proportion of cases of uterine displacements, a comparatively small number of well-fitting pessaries, in the hands of intelligent and skilful gynæcologists, are essential to the cure of not only the mal-position, but also of the abnormal condition of the organ which accompanies it. A pessary of whatever kind, when employed for the mechanical support of the uterus, is a foreign body, liable to do serious and perhaps fatal mischief, and never should be placed in situ without great circumspection on the part of the physician. It has no miraculous power, and its potency for harm is very much underrated.

He is of the opinion that intra-uterine or stem pessaries should seldom be used. Of the various forms of intra-vaginal pessaries in use, he prefers and employs the closed lever made of hardened rubber, and the soft elastic ring made of delicate strips of fine whalebone, covered with pure rubber, made by Tiemann & Co.

Ligation of Right Carotid Artery.—Dr. Pigne, Dupuytren (*Pacific Med. Jour.*) exhibited to the San Francisco Medical Society a patient on whom he had successfully performed the ligation of right carotid artery for aneurism. The ligature came away on the seventeenth day. In five months the tumor had entirely disappeared.

Excision of Superior Maxillary.—John P. Wall, M.D., of Tampa, Florida (*Atlanta Med. & Surg. Jour.*), records a case of excision of the superior maxillary bone, the patient being a female child of eight years. The chief interest of the case consisted in the absence of any kind of pain, the rapidity of the growth without known cause, and the rarity of such a diseased condition of this bone in children.

Treatment of Consumption at the Brompton Hospital.—T. G. Roddick, M.D., House Surgeon to Montreal Gen'l. Hosp'l., writing from London to the *Canada Medical and Surgical Journal*, says that two thousand gallons of cod-liver oil are consumed in that institution in a year. Lead, turpentine, and gallic acid are the sheet-anchors there in hæmoptysis. Although the physicians are beginning to use ergotine hypodermically with moderate success, they do not depend on the latter remedy in severe cases.

Chronic Eczema of the Extremities.—Dr. Mac Callum, of the Montreal Gen'l. Hosp'l. (*Canada Med. & Surg. Journ.*, Nov., 1872), successfully treated an obstinate case of this affection, the patient, male, being 42 years old, as follows: A solution of Potassa Caustica gr. v, to water ℥ ij, was used outwardly; being brushed lightly over the eruption once daily. The following mixture was ordered internally: R. Hydrarg. Bichlor. gr. iv; Liq. Arsenic. ♏xv; Acid Hydrochlor. dil. ʒ iss; Aquæ ad ℥ viij; M.—℥ ss, ter die.

Bromide of Potassium.—The subjoined conclusions concerning bromide of potassium are noted by M. Gonzales Echeverria, of New York (*Phila. Med*

Times), based on clinical facts: The remedy operates actively in a paralyzing manner on the excito-motor power of the sympathetic and spinal nervous system, and produces cerebral congestion. It is not a specific for epilepsy, but may contribute most efficiently to arrest the fits, by suspending reflex excitability of the spinal cord in a more uniform and active manner than any of its kindred salts. The benefits of the bromide of potassium increase and are better secured by administering it combined with conium, ergot, arsenic, and strychnia. Sixty grains is the average daily amount of bromide of potassium required in ordinary cases of epilepsy, but it is necessary to keep epileptics, at different intervals during the progress of their attacks, under the full physiological effects of the bromide, to suspend it until the bromism is dispelled, and then to resume the salt again in ordinary doses. It alone exerts little or no effect on the attacks of *petit mal*, unless associated with large doses of ergotine (gr. vi to gr. xvi) and conium. The remedy should never be discontinued suddenly, even when the epileptic fits have not recurred in a long time, but the dose of the salt should be gradually decreased, and the treatment left off insensibly, when there is every indication of the complete eradication of the epileptic habit. Nothing proves that the efficacy of the bromide of potassium in epilepsy bears any relation to the existence or severity of the bromide eruption. Arsenic prevents or mitigates it, and acts further as a valuable tonic. Coffee is one of the best means of correcting the unpleasant action of full doses of the bromide. When it is taken by the mother in large and prolonged doses, it does not seem to have any noxious influence on the fœtus.

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, May 15, 1873.

MEDICAL EXAMINATIONS FOR LIFE-INSURANCE.

In the present issue we commence the monthly publication of articles which shall be of special and practical interest to every medical man who may be called upon to make examinations for life-insurance. The importance of being able to make such examinations properly cannot be overestimated, and no means within the reach of the medical examiners on the one hand, and the life-insurance companies on the other, should be neglected to found the system upon a thoroughly intelligible and scientific basis.

Many life-insurance companies imagine that they sufficiently protect themselves against the ordinary mistakes of their medical examiners by issuing a few-paged pamphlet of instructions. Many of these are very carefully drawn up by the medical director of the home office, being the results of his personal experience only in the management of his department. As a rule, these items of instruction are condensed to the smallest possible space, and give no more idea of the reasons for a decision by the parties for whom they are intended than does an ordinary time-table give the traveller a satisfactory knowledge of the country through which he is passing. This has become a necessity created by the life-insurance companies, who take a merely business view of the subject, and who imagine that the nearer they can bring the whole matter of medical examination to a business system the better able will they be to draw the line between profit and loss. The truth is, as in many departments of science where a mere professional opinion is to be the basis of action, there are many matters to be taken into consideration which no set of rules, however carefully made, can directly reach.

Viewing the matter in its scientific aspect the conclusion is inevitable, that an opinion is valuable in proportion to the thoroughness of the study of those principles upon which such an opinion is founded. Such a study should be carried on for the sole purpose of arriving at the truth: questions should be viewed in every aspect, modifying conditions should be carefully considered, and controlling influences should be thoroughly understood. In no other way can the foundation for a sound, conservative, and comprehensive opinion be founded. We speak advisedly when we say that the great questions concerning the true interests of life-insurance in its medical aspects have never received the amount of attention which they deserve and demand, and that the consequence is that dreadful mistakes are constantly being made by medical examiners in accepting risks for their companies. In view of supplying this requisite knowledge to medical examiners throughout the country the medical directors of all the large insurance companies of this and neighboring cities have urged us to create a life-insurance department, which shall be especially devoted to the strictly scientific discussion of all questions bearing upon medical examinations. It is perhaps unnecessary to say that everything which has the appearance of advertising shall be rigidly excluded, and that the RECORD shall continue as ever to be a thoroughly independent, strictly scientific, and practical journal. Our aim has been and shall be to discuss principles only, weigh scientific evidence, and to consider all questions of practical import with the strictest impartiality. In our life-insurance department precisely the same course will be adopted and the interests of life-insurance companies as a body will alone be considered. By such a course the articles we propose to publish will have a general interest, each company through its medical department being free to make such application of the truths brought out as the particular requirements of its business arrangements may suggest. Whatever application may be made of the principles by different companies, one thing is evident, that the general standard of medical examinations must necessarily be raised, and each examiner will be stimulated to renewed care and watchfulness in the selection of risks.

The necessity of the adoption of some general standard for opinion in medical examinations is painfully apparent in the want of a recognized scientific basis upon which to act. It is true, every examiner is entitled to an opinion, but an opinion as to a life-insurance risk is quite different from what it should be under ordinary circumstances. These opinions must vary in accordance with the appreciation of the fundamental truths which should guide them. It is notorious how differently equally good examiners estimate an applicant for life-insurance. One will reject him altogether, another will hesitatingly accept him, while a third will consider him a good risk. One

attaches but little weight to the family history, while another believes it to be his duty to reject the apparently healthiest applicant whose history is tainted with some hereditary disease. Similar differences of opinion prevail in regard to the importance to be attached to excessive or too light weight, to personal habits, to the diseases which the applicant has had, and to many other points not necessary to mention in detail. All this is due to the want of a greater uniformity in the estimation of these different questions. As our columns will be open to the supporters of both sides of all such questions, it is to be hoped that some general opinion, founded upon scientific data, may be created which shall enable the doubtful to be certain, the wavering to be more decided, and the incompetent to be safe. In this connection we would state our purpose to publish the mortuary experience of some of our older companies, who have very kindly placed their records at our disposal. These tables will be so arranged as to show how great the hereditary influences have been upon the losses of the companies, what influences certain diseases have had upon the longevity of applicants; also the influences of occupation, etc. These facts have never been published by any of our insurance companies; their value, however, as a guide to the selection of risks can hardly be overestimated.

Again: Medical examinations for life-insurance is a specialty, and, in view of its importance, should be cultivated as such. No point, however minute, should escape attention, and no opportunity should be lost to add to the stock of special knowledge upon the subject. A scientific journal is the legitimate channel for such information, affording, as it does, a ready medium for the interchange of opinion and the prompt publication of important facts. In a word, medical examiners need a current literature and an abundance of material for study.

The department of Life-insurance is to appear extra of our usual amount of reading matter, and is to be under the charge of a gentleman who is connected with one of the life-insurance companies of this city, and is, in our judgment, thoroughly competent to select such articles as may be of interest and value to the medical directors and examiners.

The addition of such a department involves, of course, an increased outlay of capital, but we are happy to say that the larger companies of this and neighboring cities, appreciating its value, have liberally subscribed to the RECORD, and have directed it sent to their examiners throughout the country. In a purely business aspect the education of their examiners will be no doubt an immense saving in insuring nothing but good and thoroughly trustworthy risks. They will recognize the possibility, by the publication of suitable articles, of creating a judicious watchfulness on the part of their examiners. Without doubt this will be the effect, and, if it be true of a single examiner of the thousands to whom this journal may be sent, the saving to companies, in the avoidance of even a single large and bad risk, will more than compensate them for any outlay which they have incurred.

In conclusion, we would state that our desire is to make this department creditable to the RECORD, and to that end we shall be ever ready to listen to suggestions for improvement from all those whose position, experience, and education entitle their opinions to respect.

THE SUPPRESSION OF PROSTITUTION.

To such as are sanguine of the good effects of legislation in the suppression of prostitution, the Eleventh Annual Report of the Police Commissioners of St. Louis, Mo., will afford much encouragement and comfort. The triumphs of the system seem to be quite complete, and it would appear that we shall soon be ready to solve the problem which has perplexed the socialist from the time that civilization itself had an existence. We are not inclined to underrate the efforts of the good men of St. Louis, in their attempts to bring about a much needed reform, but simply to call attention to the possibility that their enthusiasm has led them into the temptation of striving to prove too much.

We are informed that the moral effects of the law are:—

1st. The number of public women has uniformly decreased each year. 2d. They are more decorous in their manner in public, and the plying of their wicked trade upon the public streets has been almost entirely discontinued. 3d. That a considerable number of abandoned women have been reclaimed and restored to respectable life, and, in several cases, married. 4th. Clandestine, or private prostitution, has been materially checked, through fear of the legal consequences of such indulgence, when brought home to the offender; and that juvenile prostitution has been greatly diminished, if not wholly removed.

The system of registration, as adopted by the Board, is perhaps as perfect as any such can be made in a republican form of government, but that it is not absolutely so no one who examines the details of its operations can deny. This being the case, the registration cannot be complete—cannot give anything more than an approximative result. This has been proved to be the case in Paris and Copenhagen, where the registration was intended to be as compulsory as the most stringent enactments could make it. Notwithstanding every precaution was taken by a police whose vigilance is traditional, the mortifying acknowledgment was made that the figures fell far short of a correct representation of the actual number of courtezans in the active exercise of their trade. It can hardly be expected that even the police bureau of St. Louis can do better, and yet we are informed upon the seemingly stubborn authority of an array of figures, that the number of these public women has steadily decreased from year to year. This may be probable, but hardly possi-

ble. There is a more rational method of explaining this decrease in the figures than by the supposition that the operation of the law is a success. In the first place, we maintain that no law can ever be made that will make it impossible of evasion, and there will always be some who will evade it, do what we may to prevent them. The majority of criminals, it is true, will at first be overawed with the prospect of penalties, and will from very fear compel themselves to abide by its provisions. This can be assumed in the present instance, at least, to be one of the reasons why the registration was at first comparatively complete. After a while, however, a certain proportion grow defiant, and boldly ignore law. As a result, the number registered may be less, while in reality the actual number who should be registered may be the same. This is the case with every enactment which appears to the parties directly interested to be calculated to restrict what they may be pleased to call their individual liberties.

Among the results of the St. Louis law, we read that the conduct of these courtezans is more decorous in public; in fact, that the "plying of their wicked trade" on the public streets has almost entirely discontinued. These assertions can be more reasonably accepted as facts, inasmuch as there is not much chance to escape direct punishment for the open violations of ordinances which the authorities take a special pride in enforcing. This is, perhaps, the smallest return the suspected ones can make for the tacit toleration of their crimes in private.

We are also ready to admit that a considerable number of abandoned women eventually take a turn for the better; that many cease to follow a shameful career and lead respectable lives, and that not a small proportion get married. But we see no special reason why the operation of any law can bring about such results. On the contrary, the very perversity of human nature is such, that actual legal compulsion to perform a strictly moral obligation would be not only entirely barren of good results, but would stimulate the otherwise rightly disposed to rebel against their better inclinations. The carefully collated statistics of *Le Bureau des Mœurs*, the department having sole charge of the Parisian prostitutes, show that the whole number of these abandoned women change every four years. This period is named by authorities as the average duration of the life of a prostitute. A certain proportion of these unfortunates die, but a very large majority of their own accord become respectable, and not a few, as we have before intimated, marry. In other countries, Great Britain for instance, this period is longer, averaging between five and six years, but the ultimate results are much the same. Parent Duchatelet asserts that the greater majority reform at the end of the first year.

It is equally preposterous to suppose that any law can have any direct effect in checking clandestine prostitution. Far from so doing, it is apt to increase it, for reasons which are at once obvious to all who have given attention to the subject. This was actually proved to be the case in Paris, and was believed to be in direct proportion to the rigorous enforcement of the prostitution laws.

The system of licensing houses of public prostitution is a good one, so far as it goes, and the use of the money thus obtained in establishing a hospital and reformatory school, as is being done in St. Louis, gives the law a truly practical turn. While the law may do very little towards checking prostitution it certainly can do the next best thing in mitigating the effects of the vice. It is well known that courtezans are especially prone to contract venereal disease, and a hospital devoted to its treatment is a necessity in every community. Not less so is a reformatory school, where the repentants, who are always in a large majority, can be aided in their efforts to become respectable, and have that charity shown them which they are made to believe they can never expect from even a Christian community.

If for no other reasons, the citizens of St. Louis deserve the thanks of humanity. Already their so-called "Social Evil Hospital" is in progress, forty thousand of the eighty thousand collected by their license system having thus far been expended in its construction. If such a practical result can crown their good intentions, every large city would do well to follow their example.

OUR ALUMNI ASSOCIATIONS.

A SHORT time since, in speaking of the amount of good which Alumni Associations could accomplish, we alluded to the establishment of extra professorships. We are happy to state, that such a suggestion has already taken a practical turn with the Alumni of the College of Physicians and Surgeons, who have declared their intention of raising one hundred thousand dollars for the permanent endowment of a Chair of Pathological Anatomy, and the establishment of working laboratories for the students. Let us hope that our sister organizations in this and other cities will take the lesson to heart

Reviews and Notices of Books.

A TREATISE ON APOPLEXY. By JOHN A. LEDELL, A.M., M.D., ex-Professor of Anatomy at the National Medical College, Washington, D. C. New York: Wm. Wood & Co. 1873.

THIS volume is an admirable specimen of the best kind of American medical literature, for it has both the distinguishing virtues and the defects of the class.

It is sufficiently comprehensive in its conception, clear and practical in its execution; the most important points are placed in just relief, and a large amount of almost new information is conveyed in so agreeable a

style, that it is easy for the reader to forget that he is learning anything. On the other hand, little or none of this newest information is derived from original researches of the author, whose erudition even, to judge by the bibliographical references, is rather commonplace. These references are made far too largely to text and compendiums, such as the Sydenham Year Book and Retrospect. All the necessary information seems to have been collected, but we rather miss the traces of minute and laborious investigation, either literary or experimental, which characterize the works of continental writers. On the other hand the author's clinical experience has been well handled, and the contributions from it are carefully analyzed, and constitute a valuable feature of the book.

The new definition of the term apoplexy, so much needed, is given with great clearness in the first chapter. "Apoplexy is a disease of the brain, characterized by sudden abolition of consciousness, feeling, and voluntary motion, produced, not by injury nor poison, nor heat, but by some morbid action in the brain itself." * * "It is not synonymous with cerebral hemorrhage. * * which indeed is comparatively seldom attended by the phenomena of apoplexy." This affirmation is based upon the author's experience, is supported also by the authority of Rousseau and of Abercrombie. "Apoplexy frequently results from sudden hyperæmia. * * or from cerebral anæmia — the consequence of an embolus of a large artery, or of sudden violent emotion; or from a profuse effusion of serum, and œdema of substance of brain." The author enumerates five distinct forms of apoplexy, or rather four pathological conditions that may be attended by the apoplectiform ictus; namely, hyperæmia of brain or membranes, serous effusion, hemorrhage, embolism, and finally embraces, under the name of nervous apoplexy, those cases in which death has occurred amidst all the phenomena of the apoplectic ictus, while however no serious cerebral lesions have been discoverable at the post mortem. But the ultimate effect of these different conditions, or the pathogeny of the apoplectic stroke, is, according to the author, always the same, namely, production of sudden cerebral anæmia. This is the famous explanation given by Niemeyer, who claims that in congestion of the brain the distention of the veins prevents an influx of arterial blood into the capillaries; that in œdema, whether depending on congestion or on Bright's disease, the capillaries are compressed by the fluid, and in hemorrhage, tumor, or abscess, that they are again compressed on account of the encroachment made on the limited intra-cranial space. "Capillary hemorrhage produces no apoplexy. The anæmia resulting from cerebral embolism 'admits of no room for doubt,' and nervous apoplexy is in all probability an intense form of cerebral anæmia, suddenly produced by spasmodic contraction of the cerebral arteries."

The author corroborates Niemeyer's views by his own direct observations of extreme anæmia of the brain on the living subject, occurring in consequence of fracture of the skull.

The author justly remarks that the causation of apoplexy is quite complex, since various influences may coincide and combine to deprive the nerve-cells of their nutrient blood. Some interesting statistics of age are given, by which it is shown that the proportion of deaths from apoplexy among children is much larger than is generally supposed. In New York, from 1867 to 1869, 68 children under ten years of age died of apoplexy, and among these 43 were less than a year old. "Scarcely any year of life is more liable to the disease than the first one." It is this fact that has led the writer to devote a special chapter to infantile apoplexy. The prevalence of the disease is explained by the soft texture of the brain during infancy, affording less support to the blood-vessels; by the flexibility of the sutures and fontanelles, which on the one hand favors the engorgement of cerebral vessels whenever hyperæmia occurs, and on the other permits atmospheric pressure to aggravate the anæmia that may have been originally occasioned by any causes of general debility; finally, by the fact that œdema of the brain substance occurs more readily in these young subjects than in adults. The intense nutritive activity of the brain in young subjects is also a predisposing cause, as for all cerebral affections. Several very interesting cases are related of apoplectic coma, as a fatal termination to marasmus, and to acute diarrhœa. Cerebral hemorrhage especially affects cachectic children, and is remarkable for the fact that it occurs in the cavity of the arachnoid much more frequently than in the substance of the brain; the reverse is the case with adults. No explanation is offered of this circumstance. In the chapter on adult cerebral hemorrhage, the description of preliminary symptoms is mainly borrowed from Forbes Winslow, and the frequent references to the work of this well-known writer are rather tedious. The interesting question of the localization of the lesion of aphasia is too summarily disposed of by a quotation from Hammond's "Treatise on Nervous Diseases." Hemiplegia, although the most characteristic symptom of cerebral hemorrhage, has been observed in congestion, syphilis, and rheumatism, and is well known to be caused by embolism. The opinions of Charcot and Vulpian in regard to the dependence of hæmatoma of the dura mater upon a pachymeningitis are unqualifiedly accepted.

A special chapter is devoted to cerebral rheumatism, of which six distinct forms are described: 1st, apoplectic and apoplectiform; 2d, paralytic; 3d psychical, or that which has mental alienation for its essential feature; 4th, convulsive; 5th, choreic; 6th, meningitic, with meningeal inflammation.

The apoplectic form is generally due to cerebral embolism, but sometimes is not attended by any lesion, and this is always the case with the apoplectiform variety. So the paralytic form is found sometimes with, sometimes without a lesion. But the psychical, convulsive and choreic forms leave no anatomical trace behind them, and "cerebral rheumatism is thus for the most part a neurosis depending on vitiated blood, and not an inflammation." The same pathogeny is accepted for cerebral gout.

The section on treatment is of more importance in this than in the other chapters, for much more may be done. The author insists on the excessive rise of temperature that has been observed in nearly all cases of dangerous cerebral rheumatism, and considers the reduction of temperature to be the first indication. The wet pack, in bag, veratrum viride and sulphate of quinine, are the means chiefly recommended to meet this indication.

Among the most novel suggestions for the treatment of apoplexy, is the employment of arsenious acid as a specific in the preliminary cerebral congestion. This suggestion is borrowed from Lamare Picquot, and from Lüsle, director of the Marseilles Lunatic Asylum. The dose is the one-fifth of a grain three times a day. Belladonna or atropine, one-sixtieth grain, is recommended by the author when apoplexy is threatened in the course of Bright's disease. It is claimed to be a remedy for renal congestions. But we believe that the diuresis that is indeed an effect of atropine, is not a

proof of lessened congestion, but of stimulation to the secretory functions of the kidney by the rapid elimination of the alkaloid.

The last chapter in the book is appropriate to the times: it is devoted to epidemic cerebro-spinal meningitis. The observations upon which this chapter is based have been largely drawn from the New York epidemic of 1872.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, March 12, 1873.

DR. ERSKINE MASON, PRESIDENT, in the Chair.

TRAUMATIC STRICTURE—DIVULSION—SUDDEN DEATH FROM URÆMIA.

DR. E. L. KEYES presented the kidneys, ureters and bladder of a patient who had died thirty-four hours after internal urethrotomy. The case being of interest, Dr. Keyes detailed it at length. In May, 1871, the patient, a large, finely-built fellow, aged 22, came from out of town for relief of stricture. He urinated with great pain in a dribbling manner every three hours by day and two or three times nightly. The fluid was muddy with blood and pus. When examined it was found to be neutral, full of pus and blood, with not more albumen than the blood would account for. No casts were found.

Examination revealed a perfectly healthy urethra, without stricture or band of any sort for four and a half inches. The canal however was very hyperæsthetic. The size of the meatus was 15. Beyond 4½ inches, only a Benas filiform bougie would penetrate, and this was tightly grasped on withdrawal.

The patient ascribed his stricture to a gonorrhœa which he had acquired in July, 1869, before which date he had had no venereal disease nor any urethral trouble of which he was sensible. In July, 1870, one year after his gonorrhœa, he had retention. A surgeon to whom he applied broke a silver catheter in attempts at forced catheterism, but succeeded in forcing another silver instrument (No. 7) through the stricture. A good deal of blood was lost, but the retention was relieved. Upon cross-questioning it came out that the patient had fallen across a fence, upon which he was walking, at the age of six. Both testicles swelled at the time, but the patient does not remember that instruments were used to relieve his bladder nor that he passed blood by the urethra. Dr. Keyes believed the stricture to be traumatic in its origin, because it had proved so tough, so tight and so resisting at the end of one year from gonorrhœa, and because there were no evidences of structural lesions of the urethra forward of 4½ inches.

After the first instrument was passed in July, 1870, the patient had what he called "severe intermittent fever," which set in the next day, and lasted three months. Between July, 1870, and May, 1871, attempts at catheterization had been made about twelve times, the instrument sometimes going into the bladder, but usually failing to pass the stricture. Every attempt to use instruments had been invariably followed by chill and fever (urethral fever).

After the passage of the Benas bougie by Dr. Keyes, the patient had several slight chills and almost complete retention. These passed off, and on the fourth day, the patient being in bed, divulsion of the stricture, to size 20 (Eng.), was performed, with Sir Henry Thomson's instrument upon a whalebone guide, without an anæsthetic. This was the first operation ever performed upon the patient's urethra not followed by a chill. No bad symptoms ensued. On the seventh day the patient passed 15 for himself, and left the city, carrying 12, 14, and 15 conical steel sounds with him, with proper instructions for their continuous use. Notwithstanding divulsion had been carried to 20, 15 was grasped by the stricture somewhat, showing that its fibres had not been efficiently torn. The patient declared that he had never passed such a stream of urine in his life, even before his gonorrhœa in 1869—this being another proof that his stricture antedated his urethral inflammation, and was due to his injury at the age of six.

In March, 1873, the patient again presented himself for treatment. He had continued to use his 15 without difficulty, and had prolonged the intervals of its insertion to one month up to the end of November, 1872, when he had contracted a new gonorrhœa. This prevented the use of the sound for three months, and on trying to pass twelve in February, it had penetrated the stricture with great pain and difficulty, and considerably aggravated the bladder-symptoms (frequency of urination, pain, &c.), which had come on again with his gonorrhœa. He had consequently omitted any further auto-manipulation and came to the city in March for relief, demanding a new operation, and absolutely refusing to stay in the city for more than a week. Examination showed the stricture to have recontracted to six, to be inflamed and exceedingly sensitive. The urine contained blood and pus, the bladder was in a peculiarly irritable condition, although the urine was still faintly acid. Internal urethrotomy was decided upon; 1st, because the stricture was inflamed, and so sensitive that it was doubted if instruments would be tolerated afterwards, so as to allow the patient to resume control over his urethra in a week's time. 2d, because previous divulsion to 20 (Eng.) had failed to relieve the strictured point sufficiently. 3d, because it was believed that a small incision through the stricture upon the stretch would accomplish more good with less violence.

No chill followed the introduction of No. 6 upon the date of the patient's re-application for treatment. He was instructed to take five grains of the sulphate of quinine and fifteen grains of the citrate of potash every eight hours. Twenty-four hours after the exploratory passage of No 6, the patient being in bed, without an anæsthetic, a cut not over a line in depth was made through the stricture, which had been previously accurately located by means of a small bulbous sound. Dr. Otis's divulsing urethrotome was used. A very slight quantity of blood followed the withdrawal of the instrument. Within half an hour a severe chill ensued, which lasted about two hours. Eight ounces of urine slightly tinged with blood were passed. Severe and protracted vomiting and purging accompanied the chill, with intense prostration, a pulse of collapse, small, soft, flickering, about 160 to the minute. Temperature slightly raised. Skin not dryer than normal. Seven drops of Magendie's solution of morphine were thrown under the skin of the arm, with the two-hundredth of a grain of sulphate of atropia. Within the next four hours the pulse came down to 120, but continued weak. Urine was twice passed, at first six ounces slightly bloody, then three ounces decidedly red with blood. The nausea disappeared, the patient took quinine, coffee and some alkali, stated that the pains in his head and bones, which had been severe since his chill, were lessening,

and that he thought he would sleep, it being after 9 P.M. The patient had never been conscious of any kidney disease nor had given any symptoms of any renal malady. He was left in charge of a nurse with instructions to administer two teaspoonfuls of liq. ammon. acetat. every two hours, and Dover's powder in case of restlessness. The latter was not given. Early on the following morning, when first seen, the patient presented alarming symptoms. He had not urinated since 9 P.M. of the previous day, and his bladder was empty. His whole surface was cyanosed, and he appeared stupefied, although perfectly intelligent. Pupils contracted. Severe pain in head. Pulse almost gone at the wrists. Dr. Markoe saw the patient in consultation, agreed that suppression with uræmia had occurred, and that the prospect was exceedingly gloomy. Six wet cups were applied over the kidneys, and eight ounces of blood drawn; hot-air bath was put into action and continued till death; one-quarter of a grain of elaterium was given by the mouth. A profuse watery stool occurred within three hours, and the skin became quite moist over the face, thighs and feet. One-twelfth of a grain of elaterium was ordered. Half-ounce doses of infusion of digitalis were given every two hours at the suggestion of Dr. Van Buren, who saw the patient in consultation. A little urine was passed with profuse watery stools during the afternoon, but the patient continued cyanosed and almost pulseless, getting gradually but steadily more stupefied. At 6 P.M. Dr. Loomis saw the patient, who was then nearly comatose and evidently dying. At his suggestion brandy was given by the mouth and by the rectum, but the latter was not retained, as the sphincter was paralyzed. After two hours the pulse rallied a little at the wrist, and gtt. x. Magendie were injected subcutaneously, followed by gr. x. quinine, also subcutaneously. Breathing became slightly stertorous after an hour, the patient became comatose and died quietly. Autopsy two and one-half hours after death, with the assistance of Dr. Lee. Rigor mortis marked. Surface mottled in purple. Permission was only given to open the abdomen. No mutilation was allowed. All the abdominal viscera were normal, except those belonging to the urinary tract. Spleen somewhat large and turgescent. The bladder was removed in front of the apex of the prostate and was taken out with the ureters and kidneys. The urethra behind the stricture was not dilated. The finger pushed forcibly into the urethra from the pelvis was arrested by the stricture. A steel sound (No. 7) passed readily through the latter, encountering the finger. The prostate was normal, its sinus congested. The bladder was immensely hypertrophied, its walls being about three-quarters of an inch thick. Trabeculæ of muscular tissue stood out under the mucous membrane, but there was no sacculation. The mucous membrane was turgid and covered with small ecchymoses. The right ureter was dilated to the size of the thumb, its walls were thickened, its mucous surface injected. The pelvis of the right kidney was in a similar condition, slightly dilated. The cortical and pyramidal portions of the kidney were atrophied partly, and there was marked evidence of localized fatty degeneration. The left ureter was as large as the small intestine, much thickened, with its mucous membrane much injected. It was absolutely occluded at one-half inch from its vesical orifice, so that fluid could not pass. It was distended with urine containing a little pus, not decomposed seemingly, and with no ammoniacal odor. The left kidney was decidedly atrophied, its pelvis largely dilated, and two small abscesses were found in the cortical substance of the organ. The whole substance of both kidneys was intensely gorged with blood.

In answer to a question from Dr. Keyes in reference to any influence which the existence of Bright's disease might have upon the operations upon the urethra, Dr. Mason remarked, that he had divulsed and cut strictures in several cases where renal trouble was unquestioned and without any bad results.

Dr. Keyes remarked that he had a somewhat similar experience, referring, in connection with the statement, to the case of a gentleman aged 70, who had had stricture for a great number of years, who was at the present time under treatment for the same, and who had had symptoms of Bright's disease for a very considerable period. After dilating the stricture at first with whalebone filiform bougies, and afterwards with soft instruments to the size of No. 3, an attempt was made to pass the next largest size, when it became arrested, necessitating the employment of a little force to effect its passage. This procedure was followed by a very little blood, an intense chill, and a distinct attack of urethral fever, but with no suppression. This confined him to his bed for a period of two weeks. Concluding finally to take the risk of divulsion, a Thompson's Divulsor was passed over a filiform bougie and the stricture divulsed to No. 6. No inconvenience whatever attended this operation, and the different sizes of bougies had been introduced, until, at the time of reporting the case, a No. 11 could be used.

Dr. Otis, in connection with the dependence of actual death from urethral fever and suppression upon injuries to the urethra, referred to two or three cases of the sort previously presented to the Society, *vide* Medical Record (Vol. VII. p. 158). He also alluded to another case, the particulars of which were sent to him by Dr. Done, of Yokohama, Japan. During the process of dilatation the patient was attacked with urethral fever, in consequence of a small amount of force being used, and died on the third day.

In all these cases the injury to the urethra seems to have been the starting-point, but the degree of injury, or the character of the instrument used, or the operation resorted to, seemed to have very little if any connection with the result that might obtain.

Dr. Jacobi agreed with Dr. Keyes in ascribing the death of his (Dr. K.'s) patient to uræmia. The explosion of the symptoms of uræmia after the operation was to be explained by the condition of the specimens. The patient had a bilateral nephritis, there was dilatation of both pelves, on the right side a considerable atrophy of the pelvic tissue, a few abscesses with very thick pyogenic walls, with the exudation of acute congestion, a pale condition of the organ, the result of a long-continued diffused inflammation.

The left kidney was in a better condition, but was far from being normal. In some places the border between the cortical and inner substance had almost disappeared.

The operation was just as legitimate under the circumstances as was death itself. In all probability the man must have died of the chill following the introduction of a catheter or sound. Very little is required when the kidneys are in that condition to start a train of symptoms which finally end in death. In regard to a previous knowledge of such a case there are many obstacles in the way, not the least of which are the absence of casts, albuminuria, and other usual signs of kidney disease. And even if the diagnosis had been made, the Dr. (K.) would have operated in spite of them.

Dr. Loomis stated that he had seen the patient during life, but his appearance was different from any that he had seen dying from uræmia. He

was inclined to believe that said symptoms resembled those described by Harley under the name of ammonæmia, in which the blood became poisoned by urine decomposing in some of the urinary cavities.

Dr. Mary C. Putnam remarked that the same idea was held by Professor Gosselin, of Paris, in explaining the sudden cause of death of a young girl after the extraction of a foreign body from her bladder.

Dr. Keyes asked if this patient had ammonæmia alone, why should he not have shown some trouble previously in connection with his former numerous chills?

Dr. Putnam. The pus decomposing in the pelvis of the kidney might cause it.

Dr. Keyes. This can hardly be allowed, inasmuch as we have numerous cases of such a sort where no such symptoms occur. Another fact in connection with the case was of importance, in regard to one of the assigned causes of this variety of nephritis on the propagation of the inflammation along the continuous surface of the mucous membrane. Although this might account for trouble in the right kidney, it could not have been explained on the ground of continuous mucous membrane on the left side.

The urine was faintly acid before the operation, and there was no ammoniacal odor about it at any time.

(To be continued.)

MEDICAL LIBRARY AND JOURNAL ASSOCIATION OF NEW YORK.

Stated Reunion, March 21, 1873.

Dr. John C. Peters, President, in the Chair.

PATHOLOGY AND TREATMENT OF PYREXIA.

Dr. W. H. Draper premised his remarks on "Pathology and Treatment of Pyrexia," by saying that he did not propose to offer an exhaustive essay on the subject, as accurate investigations had only just commenced.

He divided the signs of fever into objective and subjective. Of the first, only the elevation of body-heat is always present. With the second, none of these are constant, with the exception of mental and physical prostration, and these are not always.

In the approaching exciting causes of combustive process, various theories were to be considered. Handfield Jones says that the primary process is a paresis of the sympathetic. Another advocates the chemical theory, namely, the introduction into the system of a ferment. The experiments of Billroth show that septic fever is a process of fermentation, and traumatic fever exhibits an intoxication of the blood. The speaker was very certain that febrile influences were produced by neurotic influences.

In regard to the treatment of pyrexia, the introduction of the thermometer may be said to have revealed the diagnosis and prognosis of fever, and two things should be looked after. First, excessive amount of heat, showing an exhaustion of vital power; second, the waste of nitrogenous tissue accumulating in the circulation.

In controlling fever-heat and waste, quinine, digitalis, and calomel were useful, and perhaps aconite and belladonna. Then came in baths, diuretics, food, and alcoholics.

According to the recent investigations of Binz, quinine acts upon the blood, and not upon the nervous system. Whatever is the explanation, clinical experience is the only test, and we know that quinine is more and more given in fevers which are regarded as zymotic in their origin. Whether it checks fermentation, neutralizes the poison, or acts upon the nervous system we know not. As for alcohol, doses which would intoxicate and produce disastrous results in health, would be consumed with benefit in the febrile patient and not recognized in the breath. The doctrine of correlation of forces has here a distinct example. Alcohol supplies energy, is an antipyretic, and not strictly a stimulant in disease. Clinical experience supported this view. In concluding, he believed that the use of alcohol in fever could be defended, as it was the most reliable of the antipyretic remedies.

Dr. Austin Flint remarked that the subject was an important one, considering the extent of the subject. The recital of facts shows that we have no actual knowledge of the cause of pyrexia. The treatment must be guided by the results of clinical experience, and the unsettled views should impress upon medical men the necessity of giving due rank to conclusions from these results. Whether the general phenomena presented may not be caused by one of the phenomena, like heat, remains yet to be determined. It is a common thing to find the increase of pyrexia denoted by temperature not as well noted by the pulse, and here is a field for a very important study and clinical observation.

As to the management of fever, there was an important remedy which had not been mentioned by the author, one a favorite with the Germans, namely, the direct application of cold to the body, to abstract the heat. He was led last winter to read an ancient work by James Curry on cold affusions, and was very much pleased with it. His recital of many cases treated by this method shows that they are as valuable to us today as they were then. Dr. Curry made also a large number of experiments upon healthy persons, as well as the sick; and even *then* he used the thermometer, not only under the tongue but in the axilla. He constructed a thermometer similar to those in use at the present time. It was interesting to recur to his researches.

Dr. Peaslee said that he belonged to the class which had been mentioned, and in commending Dr. Draper's paper he would enter a *caveat* at the same time. The profession must not mistake theories for facts, although they are useful aids for their advancement; it was only by bringing out ideas that we can ever arrive at the facts. Just how quinine keeps down the fever we do not know. When we arrive at the point, that it is an antipyretic medicine, then we must find out what other remedy acts in the same way. If Liebreich had not experimented much we should not have had chloral. Practically, we must hold on to clinical research.

It was high time, and he knew that Dr. Flint would coincide, that professors in our medical colleges should not only teach the theory and practice of medicine, but should also be professors of the *science* of medicine. Alcohol can be given so as to increase or decrease the temperature; in small doses it is a sedative, in larger doses it is a stimulant. It is not desirable to administer alcohol in disease where it acts as a stimulant.

Dr. A. H. Smith spoke as follows: I wish to say a word in reference to urea as a product of combustion. It is a product of combustion as is smoke or soot, but like smoke or soot the quantity formed is a measure of the incompleteness of the combustive process. If we introduce more oxygen into the system, less urea is formed, just as when we afford more oxygen to a gas jet which is smoking we stop the formation of lampblack. In urea we have besides the oxygen, carbon,

hydrogen, and nitrogen; and the quantity of these is greatly in excess of the proportion of oxygen present. A higher degree of oxidation tends to break up the urea into substances of a less complex constitution. That urea results from imperfect combustion is proven, I think, by experiment and by clinical facts. Some experiments of my own go to show that increasing the amount of oxygen inhaled diminishes the quantity of urea excreted. And conversely, it is observed that in many diseases in which respiration is impeded, the excretion of urea is increased. This is notably the case in pneumonia.

I am inclined to regard an elevated temperature as an evidence of impaired or deficient vitality. Fever is a leading symptom in starvation, and in all diseases in which it occurs there is a rapid decline of vital force. We all know that vitality exercises a controlling influence over ordinary chemical affinity, so that a group of elements which, if left to themselves, would form a given substance, combine in an entirely different manner, and constitute an entirely different body when coerced by the organic force. When this force is withdrawn the natural chemical affinities resume their action, the complex organic body is pulled to pieces, and the elements rearrange themselves in simpler inorganic combinations. This constitutes the process of decay.

Hence it would appear that the vital force is an inhibitory power, restraining chemical action; and just in proportion as it is lowered, the tendency to excessive chemical action will be apparent.

With regard to alcohol, it seems to me that in cases suitable for its use it acts merely as an article of food, which is easily assimilated, and which, by its consumption within the body, evolves vital energy. The doctrine of the correlation and conservation of forces, to which Dr. Draper has referred, is based upon the assumption, which has been abundantly proven, that there can be no force developed without consumption of material. In the locomotive the force results from the consumption of coal; in the galvanic battery, from the consumption of the zinc; while animal power results from the consumption of food, which has undergone a transformation into muscular tissue.

Seen in this light, alcohol would bring about a reduction of temperature by increasing the vital force, and thus restraining undue chemical activity.

Dr. A. L. Loomis confessed that he was in darkness in regard to the causes of fever, which were numerous and varied. In different cases it may be caused by a ferment, or blood-changes from external causes. Quinine does not seem to act the same in all cases. In phthisis he gives it to arrest tissue changes. His theory is that it acts as an antipyretic upon the nervous system. As regards alcohol being an antipyretic, his experience showed that it acts best in those cases in which the patient has been addicted to alcohol—the temperature being lowered. In those patients who have not been in the habit of using alcohol he would hesitate to give it. In closing, he said that he was much interested in Dr. Draper's paper.

Dr. Neftel.—The interesting paper of Dr. Draper gives an account of the state of our knowledge as it was when Wünderlich published his work on animal heat in morbid conditions. Since that time, however, five years have elapsed, during which most important experimental researches on this subject have been made by Liebermeister, Senator Horwath, Hueter, and others. The increase of the body temperature being the most pathognomonic sign of fever, the theory of the latter is based to a great extent on the theory of animal heat. With reference to this we know that the normal temperature of warm-blooded animals and man remains constant; that its fluctuations, called forth by different means, are comparatively insignificant and only within the range of a few degrees; that the tendency of the system is invariably to return to its standard temperature, which, if increased or diminished beyond certain limits, is incompatible with life. Lately Horwath has discovered a most remarkable fact, which seems not to be in accordance with the generally adopted physiological laws. He found by very exact thermometrical observations that during hybernation animals (Spermophilus Citillus), whose normal temperature is the same as in other warm-blooded animals, about 37° C., assume the temperature of the surrounding medium. Thus they may be cooled for a considerable time to 2° C. and more, viz., almost to the freezing-point, and yet awake and continue to live.

The researches of Naunyn explain the modus operandi of low temperatures in warm-blooded animals. It was known before him that by freezing the red blood-corpuscles are dissolved. He showed that the smallest quantity of dissolved blood-corpuscles injected into the circulation acts in the most deleterious manner upon the organs, produces extensive coagulations, and invariably kills the animals. It is very probable that death from freezing originates in the same manner.

Under normal conditions the system produces as much heat in half an hour as would increase its own temperature by 1° C., and in 24 hours by 48° C. Therefore, in order that the body-temperature should remain constant, the system must necessarily lose exactly the same quantity of heat as it produces. This is accomplished in different ways. So, for instance, if the surrounding atmosphere is very warm, then the muscular fibres of the skin and the blood-vessels dilate, more blood circulates in the dilated cutaneous blood-vessels, and therefore more heat is given away. At the same time the system is cooled through the evaporation of the increased perspiration. The same is the case when much heat is produced by muscular activity, etc. The reverse, however, takes place if the surrounding air is very cold: the skin and the cutaneous blood-vessels contract, and less heat is wasted. But besides these mechanical arrangements for regulating the body heat by radiation, conduction, etc., there must exist a nervous centre that controls the production and waste of heat. Thus in the cold bath the production of heat is considerably augmented (three or four times more than under normal conditions), even more than necessary to compensate the loss of heat, so that after a cold bath we feel warmer than before. The increased production of heat is accompanied by a corresponding increased production of carbonic acid, thus showing conclusively that the animal heat has the same source with this product of combustion (oxidation). The reverse takes place during and after a warm bath. Tscheschichin found in animals that the temperature increases rapidly and kills them, when a section is made between the medulla oblongata and the Pons Varolii. He therefore concluded that there must exist in that region an inhibitory centre for the production of animal heat.

According to Liebermeister, in fever the regulating mechanisms of heat act in the same manner as in the normal condition. The only difference is, that in the healthy animal the body heat is regulated for the standard temperature of 37° C., whereas in fever it is regulated for a higher temperature of 39, 40 or 41° C. There are two different theories with regard to the cause of increased heat in fever. Some assume that in fever the production of heat is augmented. This may be caused, for example, by the introduction of

so-called pyrogenic substances which excite the nervous centre for the production of heat, or perhaps paralyze the inhibitory centre. Traube and others think, on the contrary, that in fever the wasting of heat is diminished, thus causing an increase of the febrile temperature. This latter assumption is corroborated by the recent observations of Hueter, who found in inflammations a greater number of blood-vessels excluded from the circulation, in which the wasting of heat does not take place.

Dr. Neftel was followed by the President, who referred to a form of catarrhal fever which was of frequent occurrence and obstinate, and spoke of aconite, acetate of ammonia, and colchicum combined with aconite, as valuable febrifugic agents. If 150 grains of urea were excreted in twenty-four hours, every practitioner, he thought, would feel the importance of giving remedies which would counteract this tendency. He has had comparatively little experience with quinine and alcohol in the treatment of fevers.

The Association then adjourned.

Correspondence.

PERCY'S SO-CALLED ALKALOID HYPOPHOSPHITE.*

REJOINDER TO DR. S. R. PERCY.

By EUGÈNE PEUGNET, M.D.

The inditing of a criticism or review is neither pleasant nor easy, for it may not be accepted in the spirit in which it is intended—the advancement of our scientific knowledge. Dr. S. R. Percy, in his answer to my criticism, in the 15th of April issue of this Journal, has certainly accepted mine in the proper spirit, but as he complains that he has not been carefully read, raises several points, alleges that there are several *errors* in the criticism, and *apparently* remains unconvinced. I will answer him *seriatim*.

I. The Doctor alleges that I mean "*antidotal effects* instead of toxicology." He must pardon me if I refer him to Webster's Dictionary (revised edition) for the definition of toxicology, which is a *generic* term; therefore includes "antidotal effects."

II. He claims having "pointed out a new and reliable antidote—oxygen." This assertion is effectually *refuted* by a foot-note (page 44):—"It seems to be acknowledged that pure oil of turpentine (*free from oxygen*) is not antidotal to phosphorus." Moreover he admits in the text "that oxygenated water and spirits of turpentine are both *antidotal* to phosphorus, *provided* they are administered *before* the poison is *absorbed*."

III. The reviewers are advised to "re-read" the "Prize Essay," in order to seek for original matter. Thus, he claims that "in the first 39 pages of my (Dr. Percy's) 'Prize Essay,' I have given a large number of *analyses* proving the presence of peculiarly varied and mobile combinations in the living tissues of man and animals, and I have shown that the vegetable as well as the animal organism is a vast and complete chemical laboratory," etc. As the Doctor invites a much more *searching* criticism, I will now state that the *gist* of the first 24 pages will be found in Graham's Chemistry (Am. edition), *that* of the remaining 15 pages in the various authorities mentioned in the text and foot-notes. With the exception, however, of the Doctor's "so-called alkaloid hypophosphite," his Croton water analysis, and his *method* of extracting a substance (page 33), a nitrogenized phosphate by means of gasoline, from the germ of various vegetables, which he alleges is "one corresponding with the peculiar phosphate of the brain in man." He fails, however, to give us the *ultimate* analysis of this substance which should be the *essential* feature of an essay having such pretensions. In fact, he merely gives us *alleged* results, or more properly, *conclusions* arrived at, without describing his *modus operandi*, which it must be admitted is *essential* for the *verification* of a chemico-physiological investigation. This *omission* has also another important bearing as regards the *legumin*, a nitrogenized phosphoretted substance existing in all vegetables, but the *proportion* of phosphorus *varies* with the species from which it is extracted, and this proportion is again affected by the nature of the soil on which the plant grows. Whether these are two distinct substances or not has not been *elucidated* by Dr. Percy, at all events, in his "Prize Essay."

IV. He *alleges* that I make a chemical *error* in calling lecithine a neutral phosphoretted fatty matter, "an *acid* phosphate." True, according to the construction *it pleases* the Doctor to place on it. But as the researches of such high authorities as Gobley, Chevreul, and others have demonstrated that it is composed of three acids, two of which are simple and one compound, the phospho-glyceric, which are combined with nervine (the base) in such a manner that, *relatively speaking*, as regards the proportion (the number) of the acids to the base, it is an *acid* phosphate, oleate, or margarate.

V. The Doctor claims having found that Frémy's "acide oléophosphorique" is more than a fatty acid. This had already been demonstrated by Gobley, whose researches I presume the Doctor is familiar with, as he refers to him in his essay, but does not credit him with it. Moreover, Dr. Percy fails to give us his *modus operandi*; when *he does*, it will be time enough for *his reviewers* to *verify* his observations by *analyses* of *their own*. Until then, I for one decline accepting any one's *ad captandum* conclusions, for such they must be, if *unsupported* by *experimental* proof.

VI. He asserts that I separated the hypophosphorous acid, owing to its strong affinity for water, by decomposing his "so-called alkaloid hypophosphite." This is simply going into the *reductio ad absurdum*, for at page 53 he acknowledges that it requires boiling water (212° Fht.) to decompose the lecithine, and *his alkaloid* would, *ex necessitate*, require the same, whilst all the hypophosphorous acid can be extracted from the latter at a temperature varying from 60° to 120° Fht.

VII. He then states, that "it is a well-known chemical fact that *anhydrous hypo*phosphorous acid (P. O.) has no separate existence." There is no doubt but that *it was so* until the Doctor formed it in "*statu nascente*" in cocoa butter and lard oil, and *it is* also *true* that it cannot be separated from them in an anhydrous form.

VIII. He exclaims: "Here, at least, is a chemical discovery, but not one at variance with the laws of nature!" What? His *so-called alkaloid!* Turning to page 24, he says: "I have succeeded in converting phosphorus into anhydrous hypophosphoric acid, and so retaining it in this nascent condition until it combines with three equivalents of olein, forming a tri-

* Prize Essay, American Medical Association, 1872.

basic hypophosphite of olein, two of which are *permanently* united with the acid, the other equivalent may be exchanged for another base." Then in a footnote (page 25) he thus *flatly contradicts* it: "In the *union* with all of these oleaginous substances, *glycerine* eventually becomes the base." It is evident, *per se*, that these two assertions are self-contradictory, for it is a well-known chemical fact that glycerine is obtained by the decomposition of olein into oleic acid and glycerine. Therefore, if the first hypothesis is *correct*, it is utterly impossible for the latter *to take place*. I can only explain this self-contradiction in but one way, it is: that the Doctor realized that he could not otherwise reconcile the discrepancies between this artificial *alkaloid* and lecithine.

IX. Dr. Percy then refers us to page 15, to find a statement that the affinity of anhydrous hypophosphorous acid for water is so great, that it even robs sulphuric and hydrochloric acids of their water of combination. If Dr. Percy *will* adopt the advice *he* has so kindly given to his reviewers, and "re-read (his) my essay," he will not find *any allusion* whatever to it, on page 15, or even in *any portion* of his brochure. But, if he turns to page 21, he will there find that *it is phosphoric* acid he alludes to, and *not hypo*phosphorous acid. It is self-evident that this point in his answer is *utterly untenable*.

X. He next asserts that: "the Doctor's (my) analysis, after digesting the fluid with animal charcoal, is certainly incorrect," "for he will find both superphosphate of lime and hypophosphite of lime." That this could not arise from the charcoal is evident, for "I previously tested" its purity by exhausting all the soluble salts contained in it with distilled water. That the Valentine's beef-juice contained 13 per cent. of salts, I was well aware of, and it was needless to search for them. When the preparation is made without the beef extract, the Doctor is well aware that there are none present.

XI. The Doctor also seeks to comfort himself by asserting: that my *analysis* and my reasoning "*à priori*" prove that *he* is correct in *assuming* "that nascent hypophosphorous acid takes up two equivalents of fatty matter;" which does he mean *now*, olein, glycerine, or what? The term "fatty matter" is exceedingly *generic*. Dr. Percy is evidently "effecting a change of base." If it is glycerine he has reference to, there is no foundation for this *comforting* hypothesis, for it is a well-known chemical fact that when a fatty substance is decomposed into oleic, margaric, or stearic *acids*, and *glycerine*, that the *latter* does not again unite with the *former*. As regards the *butyrin* in cocoa butter, it would require artificial means to *reunite* the butyric acid and glycerine, as it does not take place *per se*. Therefore, this is another false hypothesis, as the *theobroma* remains *unaltered*.

XII. Finally, he finds another *alleged* error, in that I call *his* preparation "*hypo*roxidized phosphorus." There is *no doubt* about this one, but it *arises* from *my* having *thoughtlessly* adopted *his* chemical *nomenclature* as *correct*. Dr. Percy says that there are four degrees of the oxidation of phosphorus (p. 16): the oxide of phosphorus, 2 P + O; hypophosphorous acid, P + O; phosphorous acid, P + O_3; and phosphoric acid, P + O_5. It is therefore evident that the first is not an *oxide*, but a *sub*-oxide, 2 : 1, and that the second, 1 : 1, is the oxide *proper*. Then as there is in *hypo*phosphorous acid *more* oxygen than in our author's oxide, it is evident *per se* that *hyper*, which means *more*, an *excess* of, is *relatively* correct.

The Doctor himself affords us the *strongest* point in *support* of *our* criticism, by practically discarding *his* "so-called alkaloid hypophosphite," and substituting what he *calls* in one sentence, "vitalized phosphates," and in the *next*, "vitalized hypophosphites."

It is evident that Dr. Percy, in regard to his "*so-called* alkaloid," is under the impression, as shown by his own admission (page 29), that: "*There are thoughts that dwell with us until they seem to be realities, and although by strict inquiry we cannot in any way of positive reasoning prove them to be facts, we are not the less ready to accept them in our own minds as facts.*"

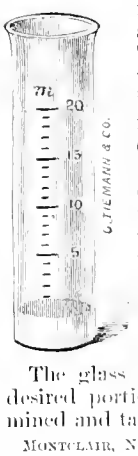
New Instruments.

A NEW GRADUATED MEASURE.

By J. W. PINKHAM, M.D.

MONTCLAIR, N. J.

HAVING frequent occasion to use the hypodermic syringe, and having long felt the need of conveniences for making my solution, especially of morphia, at the time of using it, I induced Messrs. Tiemann & Co. to make a graduated measure, suitable for the purpose, with a case having a compartment for powders. Having tested this measure, and being convinced of its accuracy as well as of its great utility, I take the liberty of asking you to call the attention of the profession to it, believing that its general adoption would do much towards lessening the number of accidents from hypodermic medication. These accidents have been due, I believe, to irritating solutions,* and to mistakes in the quantity of the remedy given, and not to anything peculiar to this mode of administration.



I find it most convenient to carry powders of the sulphate of morphia, containing half a grain each. One of these I place in the glass and throw upon it from the syringe twenty minims of warm water. If the powder remain undissolved, the contents of the glass can be taken into the syringe, and thrown back repeatedly until a perfect solution is obtained.

The glass is so graduated (see wood-cut), that any desired portion of its contents can be easily determined and taken up for use.

MONTCLAIR, N. J., *April* 4, 1873.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from April 19, 1873, *to May* 4, 1873.

MCLAREN, A. N., Surgeon.—Granted leave of absence for 60 days, to take effect from May 1, 1873. S. O. 14, Mil. Division of the Atlantic, April 16, 1873.

HEAD, J. F., Surgeon and Medical Director.—Granted 30 days leave of absence. S. O. 77, Dept. of Dakota, April 17, 1873.

By S. O. 82, War Department, A. G. O., April 18, 1873, the following changes are made:—

The following officers are relieved from their present duties and ordered to report in person to the Commanding Generals of the Departments to which they are respectively transferred for assignment to duty:—

* The development of penicillum will render solutions of the alkaloids, under favorable circumstances, unfit for use in a few hours.

SMITH, ANDERSON K., Surgeon, from the Department of the South to that of the Missouri.

GRAY, CHARLES C., Surgeon, from the Department of the East to that of Texas.

FRYER, BLENCOWE E., Surgeon, from the Department of the Missouri to that of the East.

WEEDS, JAMES F., Surgeon, from the Department of the South to that of the Lakes.

MIDDLETON, J. V. D., Assistant Surgeon, from the Department of the Gulf to that of Dakota.

WOODHULL, ALFRED A., Assistant Surgeon, relieved from duty in the Department of the Missouri, to proceed to Baltimore, Md., and report by letter thence to the Surgeon General.

The following officers are relieved from duty in the Departments set opposite their respective names, will proceed to New York City, and report thence by letter to the Surgeon General:—

GREENLEAF, CHARLES R., Assistant Surgeon, Department of the Columbia;

AZPELL, THOMAS F., Assistant Surgeon, Department of California;

BREWER, JOHN W., Assistant Surgeon, Department of the Missouri;

KOERPER, EGON A., Assistant Surgeon, and PATZKI, JULIUS H., Assistant Surgeon, Department of Texas.

HEGER, A., Surgeon. In addition to his present duties, to perform those of Medical Director of the Department. S. O. 77, C. S., Department of Dakota.

PETERS, DEWITT C., Surgeon. Granted leave of absence for 30 days. S. O. 65, Department of the Gulf, April 26, 1873.

GRAY, C. C., Surgeon. When relieved by Assistant Surgeon Matthews, to comply with orders received from War Department. S. O. 80, Department of the East, April 29, 1873.

HAPPERSETT, J. C. G., Assistant Surgeon. Relieved from duty at Fort Garland, C. T., and assigned to duty at Fort Lyon, C. T. S. O. 63, Department of the Missouri, April 26, 1873.

WOODHULL, ALFRED A., Assistant Surgeon. Relieved from duty at Fort Lyon, C. T., and to comply with S. O. 82, C. S. War Department. S. O. 63, C. S., Department of the Missouri.

BREWER, J. W., Assistant Surgeon. Relieved from duty at Camp Supply, I. T., and to comply with S. O. 82, C. S., War Department. S. O. 63, C. S., Department of the Missouri.

GARDNER, W. H., Assistant Surgeon. Relieved from duty at Fort Hays, Kansas, and assigned to duty at Camp Supply, Ind. T. S. O. 63, C. S., Department of the Missouri.

BENTLEY, EDWIN, Assistant Surgeon. To accompany Battery "G," 4th Artillery, for service in the field against the Modoc Indians. S. O. 44, Department of California, April 13, 1873.

MEACHAM, FRANK, Assistant Surgeon. Relieved from duty in Department of the Platte, to proceed to Boston, Mass., and, on arrival there, report by letter to the Surgeon General. S. O. 87, A. G. O., April 26, 1873.

WHITE, R. H., Assistant Surgeon. Relieved from duty at Mobile, Ala., and to comply with S. O. 74, C. S., A. G. O. S. O. 74, Department of the South, April 17, 1873.

GIRARD, J. B., Assistant Surgeon. Assigned to duty at Camp Apache, A. T. S. O. 21, Department of Arizona, March 31, 1873.

POPE, B. F., Assistant Surgeon. Assigned to duty at Humboldt, Tenn. S. O. 76, Department of the South, April 19, 1873.

KING, J. H. T., Assistant Surgeon. Relieved from duty in Department of the Platte, and to report in person to the Commanding General Department of the Lakes for assignment to duty. S. O. 87, C. S., A. G. O.

CORSON, J. K., Assistant Surgeon. Assigned to duty at Mobile, Ala. S. O. 74, C. S., Department of the South.

MATTHEWS, W., Assistant Surgeon. Assigned to temporary duty as Post Surgeon, Fort Wood, N. Y. H. S. O., 80, C. S. Department of the East.

MACKIN, CHARLES, Jr., Assistant Surgeon. His resignation accepted by the President, to take effect April 29, 1873. S. O. 89, War Department, A. G. O., April 30, 1873.

Medical Items and News.

THE RAISING OF CHILDREN DOUBLED.—Dr. Farr reports that the proportion of children raised has doubled within a hundred years. In London, the proportion of deaths under five were—1730 to 1749, 74.5 per cent.; 1770 to 1789, 51.5 per cent.; 1851 to 1870, 29.8 per cent.

PROF. WILLARD PARKER, of New York, made some interesting remarks on "Cancer of the Female Breast," before the New York Medical Library and Journal Association, April 18th, 1873. We shall publish them in full in a future number.

DR. J. SOLIS COHEN'S lectures before the College of Physicians of Philadelphia, being the Mütter lectures for 1872, are being published in full, with illustrations, in the *Philadelphia Medical Times*.

DR. SUSAN DISNACK, a graduate of Zurich, 1871, asked for admission into the Massachusetts Medical Society. Said Society is in doubt as to whether its charter allows the request.

DR. W. PORTER, late of the Hartford Insane Asylum, has been elected Superintendent of the New York Institution for the Instruction of the Deaf and Dumb.

NEW YORK MEDICAL AND SURGICAL SOCIETY.—The officers of this association, organized in 1834, for 1873, are as follows: *President*, Dr. Geo. A. Peters; *Vice-President*, Dr. Chas. M. Allin; *Secretary*, Dr. Geo. G. Wheelock; *Treasurer*, Dr. Robt. Watts.

DESCARTES' SKULL.—A cast of the skull of Descartes—which is kept at the Paris Garden of Plants—has been given by Prof. Gervais to the Archæological Society of Touraine. A cast has also been taken for London and another for Stockholm.

MINNESOTA STATE MEDICAL SOCIETY.—The officers of this Society for 1873 are: *President*, Dr. W. W. Sweney, of Red Wing; *1st Vice-President*, Dr. W. W. Clark, of Mankato; *2d Vice-President*, Dr. A. E. Senkler, of St. Cloud; *3d Vice-President*, Dr. M. Hagan, of St. Paul; *Treasurer*, Dr. S. B. Sheardown, of Stockton; *Recording Secretary*, Dr. Chas. E. Smith, of St. Paul; *Corresponding Secretary*, Dr. H. C. Hand, of St. Paul.

The sixth annual meeting will be held at Mankato, on the second Tuesday in June, 1873.

The London Medical Societies.—The presidents of the various medical societies of London, for 1873, are as follows: Pathological Society, Sir Wm. Jenner; Obstetrical Society, Dr. Edward J. Tilt; Harverian Society, Dr. T. Ballard; Royal Medical and Chirurgical Society, Dr. C. J. B. Williams; Clinical Society, Prescott G. Hewett; Medical Microscopical Society, Mr. Jabez Hogg.

A New Southern Medical Journal.—Drs. F. Peyre Porcher and R. A. Kinlock are the editors of the new *Charleston Medical Journal and Review*, which is to be published quarterly. The April No. contains an excellent salutatory, nine practical original papers, several reviews, and abstracts from foreign and domestic journals.

Cancer of the Liver.—H. A. West, M.D., Physician to the Louisville City Hospital (*Am. Practitioner*, March, 1873), reports a fatal case of cancer of the liver, occurring in a male, aged 65 years, in which the *post-mortem* showed that, notwithstanding extensive degeneration and disorganization of hepatic substance, there was very slight disturbance of the digestive functions. The cancerous disease existed primarily and alone in the liver. The case illustrates a fact mentioned by Andral, in his *Clinique Medicale*, namely, that many of these cases approach a fatal termination before the gravity of the disease is suspected.

American and Foreign Cities.—The area in square miles, and population to the square mile, of some of our home and foreign cities are as follows:

	Area.	No. to the square mile.
Chicago	223 square miles	1,350
London	122 " "	26,000
Philadelphia	120 " "	5,400
Boston	110 " "	2,300
San Francisco	90 " "	1,500
Paris	63 " "	28,000
Pekin	56 " "	28,500
New York City only	22 " "	43,000

The Regular Profession in Philadelphia.—The *Philadelphia Medical Register* states there are in that city 699 regular physicians; of these, 50 are on the retired list.

New York College of Pharmacy.—Thirty-three graduates received diplomas, April 1st, 1873, at the commencement of this Pharmaceutical Institution.

Trichinous Disease has been prevalent in Framingham, Mass.

Harris.—Dr. Elijah P. Harris, Prof. of Chemistry in Amherst College, Mass., has sailed for Europe. He will devote himself to study in Leipsic. The College Trustees have given him authority to expend several thousand dollars for additions to his laboratory.

Conception at Eleven Years.—Dr. Dills, of Carlisle, Ky. (*The Clinic*, March 29th, 1873), was called to attend a colored girl in labor, aged eleven years and nine months, and found a vertex presentation, first position; the pelvis was large and roomy, labor progressed rapidly, and a living child weighing nine and a half pounds was the result. The girl had never menstruated.

[Lobstein and Canes (*Medico-Chirurgical Review*, October, 1838) each relates a case in which menstruation commenced in, and continued regularly after the second year of age; in one of these cases the girl conceived in her eighth year. B. S. T.]

Homicides in New York City.—Dr. Chas. P. Russell, Registrar of Records in Health Department, states that since March 10th, 1871, when John Thomas Rosenville was hung, 104 homicides have been committed in this city; of which only one, Wm. Foster, March 21st, 1873, was executed.

Adams.—A bequest of $54,575.11 was made to the Hartford Hospital, by the will of the late Chester Adams, of Hartford, Conn.

Beale.—Medical Director Joseph Beale, U. S. Navy, has been appointed Inspector-General of hospitals and fleets, the appointment taking effect April 1, 1873.

The Medical Society of New Jersey holds its one hundredth and seventh annual meeting at Mount Holly, N. J., May 27 and 28.

Jefferson Medical College.—The Pennsylvania Legislature has recently appropriated one hundred thousand dollars to the trustees of this school as a contribution to the fund for the erection of a College Hospital.

Death of Surgeon Madison Mills.—The Surgeon General announces with regret the death of Surgeon and Brevet Brigadier-General Madison Mills, which occurred at Fort Columbus, New York Harbor, on the 28th of April.

Receiving his commission as Assistant Surgeon U. S. A. in April, 1834, Surgeon Mills' service extended over a period of thirty-nine years, during which it was his fortune to take part in the Florida war, the war with Mexico, the Utah Expedition of 1858 (as Medical Director), and the war of the Rebellion. He was Medical Director of the Department of Tennessee (General Grant's army) at the time of the siege and surrender of Vicksburg, and in December, 1864, was appointed Medical Inspector-General, the duties of which position he discharged most satisfactorily. In November, 1864, the brevets of Lieutenant-Colonel and Colonel, and in April, 1865, that of Brigadier-General were conferred upon him for faithful and meritorious services.

Possessed of unflinching determination and courage, and guided by professional abilities of a high order, his administration of the trusts confided to him was marked by a prompt efficiency and sound judgment that secured successful results, even under the most adverse circumstances.

LONGEVITY AND OTHER BIOSTATIC PECULIARITIES OF THE JEWISH RACE.*

By JOHN STOCKTON HOUGH, M.D.

EACH race, nation, class, and family of people have physical, moral, and spiritual peculiarities and immunities which always differ in degree, and often in kind, from every other race, nation, class and family; and had we the statistical data for comparison, it is more than probable that we should find this difference quite marked in several particulars, though I scarcely think it would be found so distinctive and decided as the uniformly defined differences between Christians and Jews.

These differences, I am persuaded, are not only to be attributed to a difference in physical constitution, but to differences in morals, habits, customs, occupations, observances, traditions, all of which may in some degree affect biological phenomena.

The kingdom of Prussia has kept for a greater number of years than any other, reliable statistics of the Jews† and Christians in its domains, and made the comparisons which enable them to appreciate their value as subjects. M. Legoyt‡ has analyzed these statistics for the period from 1825 to 1861 (period 1849 to 1852 excepted). He finds the increase always surpasses that of the general population—and, above all, by the excess of births § over deaths; if there are fewer adults there are more aged. The proportion of sexes is 103.37 women to 100 men, in place of 100.72 women for 100 men in the general population.

The OCCUPATIONS are as follows:

	General Population.	Jews.	
Agriculture, Gardening, and Agricultural Industry	42.53	2.18	per ct.
Industry	39.41	18.37	"
Commerce	5.17	57.33	"
Domesticity	3.25	6.73	"

In Industrial professions and Commerce we see 75.70 per cent. of the Israelites.

MARRIAGES RARE.—According to statistics in Prussia, marriages among Jews are more rare than among other religionists, as may be seen from the following statements (from Lévy,‡ p. 17).

INHABITANTS TO ONE MARRIAGE.

Years.	Evangelists.	Catholics.	Israelites.
1831	139.21	126.62	155.12
1834	102.76	103.99	120.94
1837	110.02	109.38	142.20
1840	112.08	113.61	127.58
1843	107.97	113.19	123.21
1846	112.36	122.93	134.54
1849	107.77	111.40	174.92

* NOTE.—The writer of this article deems it proper to state that he was induced to compile it through the kind invitation of the editor of this department of the RECORD, and has not sought to appear in the gratuitous position of an "elegant apologist" of the Jewish race, but merely to bring together from various sources the facts as he finds them, solely for the benefit of science, hoping that Christians who are not blinded to the advantages arising from keeping the Mosaic Laws may take heed and profit by example. He regrets that he has not, from the very short space allowed and time allotted, been able to collect more facts, and arrange them in a more acceptable manner.

† There are about 7,000,000 Jews living in the world at the present time. Their density is independent of society, religion, or government. There is one Jew to every 446 inhabitants in England, 1 in 468 in France, 1 in 42 in Russia, 1 in 33 in Austria, 1 in 105 in Germany, 1 in 61 in Turkey, and 1 in about 58 in Europe. There are probably 75,000 Jews in the United States, or 1 to every 500, of which between eight and nine thousand are in Philadelphia, or 1 to every 100 inhabitants.

‡ Journ. de la Société de Statistique de Paris, de Juillet et d'Août, 1865.

§ The Talmud says of the command to increase and multiply, "who neglects this precept commits a homicide, and it is the cause for which God abandoned Israel." The Talmud also recommends not to espouse a woman who is defective, and that the best age for marriage is 30 years.

‖ De la Vitalité de la Race Juive en Europe, Annales d'Hygiène Pub., etc. t. xxv. 2d Série, 1866, and Pamphlet. Paris, 1866, pp. 30.

Dr. Glatter * has found the same to be the fact among the Jews of Wieselburg, in Hungary. In Saxony there was 1 marriage among 113 Israelites, and 1 among 103 Christians. In Tuscany, for the year 1861, 1 to 103 Christians, and 1 to 141 Israelites. In some countries this lessened frequency of marriage among Jews was in some degree due to restrictions of municipalities and governments, which did not allow an Israelitish marriage unless the contracting parties could show some palpable means of maintaining themselves in their new social state.

This, however, has mostly disappeared, and the difference between the frequency of marriage among Jews and Christians is probably due to custom or habit of these people, who probably make better preparations to meet their obligations than Christians, in addition to the larger proportion of children and the aged among Jews, which renders the proportion of the population capable of contracting matrimony sensibly less.

FECUNDITY.—Following Lévy; not only do Israelites marry less, but they have fewer children, fewer still-births, fewer deaths among the children born alive. From the documents in Prussia, there were 29.97 inhabitants for 1 birth, while among the Christians it only required 25.21 persons from which to recruit 1 birth annually.

I would suggest that were the above facts the only ones upon which the lesser fecundity of the Jews was based, I should think the conclusion—in view of the facts already mentioned, viz., that there are more marriages, consequently a greater proportion in state of matrimony; more deaths among children of Christians, consequently larger proportion of adults, that is, persons capable of contracting marriage, besides the larger proportion of aged—as unwarranted in the premises, and of necessity erroneous, in degree at least—which last named position is corroborated by Henke,† who says that in Prussia, Christians have 4.3 children to each marriage, and Israelites 5.2—while another writer‡ says that in this monarchy for the years 1820 to 1825, the Christians had 5.35 children to each marriage and the Israelites 4.78.

At Furth, an average for 25 years gives 1 marriage to every 128 Christians, while Jews number 149 to 1 marriage. Among Christians it required but 29 inhabitants to recruit one birth, while among Jews it required 35.

AGE AT MARRIAGE.—In marriages the age of Jews is more advantageous than Christians. Of 100 persons,

Only 29 Christian men were under 30 years of age.
While 37 Jewish " " " " " " "
Only 54 Christian women " " " " " "
While 69 Jewish " " " " " " "

Under 25 years of age there were, in 100 marriages, 26 Christian unions, and 45 Jewish unions.

In 1,000 marriages in which the man was less than 45 years, the woman less than 40 years, there were 746 Christians and 782 Jews; in which the man was less than 60 years and the woman less than 45, there were 212 Christians and 170 Jews; in which the man was more than 60 years and the woman more than 45, there were 42 Christians and 48 Jews.§

CHILDREN—EXCESS OF MALE BIRTHS.—One of the most marked and unvarying physical peculiarities of this race, is the much larger proportion of boys among the births than among Christians in the same places

* Annales d'Hygiène Pub. et Med. Leg., t. xxiii. 2d Série, p. 223.

† Zeitschrift fuer die Staatsarzneikunde, t. xii. p. 230.

‡ Babbage, Edinburgh New Philos. Jour. v. 1.

§ On the number and increase of Jews in the Prussian States, &c., &c., by C. R. Weld, trans. from M. Hoffmann.

living under the same circumstances. I have collected with much care, from various sources, the following facts, and brought them together in tabular form as seen below:—

PROPORTION OF SEXES AMONG BIRTHS OF ISRAELITES.

Country.	Period.	Whole Number.	Boys to 100 Girls.
Israelites in Prussia*		(5,518 boys and 4,682 girls)	113.00
" " "	1827	(2,956 " " 2,624 ")	111.00
" " "	1820-54	(12,454 " " 11,029 ")	112.92
Christians " "	1820-54	(812,894 " " 791,580 ")	106.08
Israelites " Berlin 16 years‡			
in succession, anterior to 1820		(528 boys and 365 girls)	144.65
Israelites in Breslau, 1782 to 1800§			114.00
" " Leghorn			120.00
Christians " " ‖			104.00
Christians, legitimate, in Prussia¶			106.07
" illegitimate, " "			103.60
Jews, legitimate, " "			109.56
" illegitimate, " "			101.19

The greater proportionate number of male births among Jews may be in some degree influenced by the age of the parents at the time of marriage, as Jews marry younger than Christians; it is in some degree due to a better physical constitution, which they undoubtedly inherit, or they would not live so much longer than Christians; but most of all is this decided peculiarity due to the observance of certain Mosaic laws (Levit. c. xv. 19, 28), which physiologists have not failed to recognize.

SEXES IN THE POPULATION.—What is most remarkable in reference to the proportion of sexes, is the fact (if a fact, as stated by Lévy) of there being a smaller proportion of males *of all ages* among the Jews than in the general population, while the former have uniformly such a large excess of male births. Jews have an excess of males at birth amounting to nearly 18 per cent., while the general population have only 6½ per cent., yet, notwithstanding this, if all ages be taken in the population, Jews have 3.25 per cent. fewer males than females, while the general population have only .8 per cent. fewer males than females. This difference is certainly greater than could be accounted for by a difference in emigrants in favor of males, and is probably due to greater proportionate mortality among Jewish male infants, or greater longevity of their females; probably the latter.**

MENSTRUATION.—Raciborski†† has determined that different races begin to menstruate (reach puberty) at different ages, which indicates that some races develop with greater rapidity than others, and it is probable that this difference in the time of development may affect the probability of life. He found that 70 noble women began to menstruate at 13 yrs. 1 mo. and 5 days; 100 Hebrew women, at 14 yrs. 3 mos. and 25 days; 200 Slavonic women at 15 yrs. 3 mos. and 9 days.

IMMUNITY FROM DISEASES.—DR. Glatter (Directeur du Bureau de Statistique à Vienne), in his paper on "The Influence of Race on the Duration of Life,"§§ gives the following table illustrative of the relative frequence of disease among different races in the same locality.

	Number ill.	Number to 1,000 inhabitants.
Magyars,	6,034	534
Germans,	3,806	223
Slavonians,	1,522	182
Servians,	252	28
Jews,	1,540	32

The Jews present a remarkable immunity from intermittent fevers, convulsions, and tabes mesenterica of children, and from phlegmasiæ of the respiratory organs. They give on the other hand higher figures for *gale* and other apyretic cutaneous affections, also for gastro-intestinal catarrhs and hernias.

According to Boudin,* the first epidemic of cholera fell heavily on the Jewish race.

They have had in recent times a very marked immunity from the plague, which was so noticeable that it was the motive of odious persecutions.

Tschudi,† in speaking of the plague of 1346, says that this malady did not affect the Jews of any country. Fracastor mentions the fact that the Jews escaped completely the epidemic of the typhus of 1505. Rau‡ mentions the same immunity from typhus observed at Langeons in 1824. Ramazzini insisted on the immunity of Jews from the intermittent fevers observed at Rome, 1691.

Degner says the Jews escaped, in 1736, the epidemic of dysentery of Nimègue. Michel Lévy makes the remark that this immunity was manifest at the same time in the French and in the Israelites.§ M. Eisenmann insists on the extreme rarity of croup in the Jewish children.

The inquiry made in 1843 by the Prussian government in certain cities in the Grand Duchy of Posen, found that in several localities there existed a malady affecting the hair, of which the following races were attacked in the proportion indicated by the numbers set opposite them:—

1 in every 33 individuals of the Slavonic race.
1 " " 65 " " " Germanic "
1 " " 88 " " " Jewish "

The *Comptes Rendus* of the Minister of War gave for the civil population of the cities of Algeria the mortality below:—

	Deaths for 1000 inhabitants. 1844.	1845.
Jews'	21	36
Mussulmen	32	40
Europeans	42	45

According to Dr. Stallard, in his work on "London Pauperism," Jewish children have no hereditary syphilis, and scarcely any scrofula. Their greater tenacity of life is therefore not only due to better maternal care and nursing, but to the inheritance of a better physical constitution than the Christian child.

DURATION OF LIFE.—M. Lévy estimates that the mean average duration of life among Jews exceeds that among Christians by about 5 years. In Prussia, the civil records indicate 1.61 deaths to 100 living Jews, while for the general population of the entire kingdom it is 2.62 for 100; from which it follows that the population increases by 1.36 for 100 among Christians and 1.73 among Jews, per year. The effect of this is to double the Christian population in 51 years, while the Jews would double in 40.5 years. In 1849, Prussia computed 1 death for:

Evangelists.	Catholics.	Jews.
34.35 inhab.	30.18 inhab.	40.69 inhab.

M. Legoyt has constructed for France (from 1855 to 1859, 5 years) a table of mortality with the deaths by ages of Jews and of the total population, from which he deduces the following conclusions:

1st. At birth, the mean life of the general population rises superior to that of the Jewish population (men). 2d. At all the other ages the advantage appertains to the Jews. 3d. As for the Jewish women, their mean life does not attain to that of the general population of the same sex until the age of 60 years; but in parting from this limit they become superior.

Dr. Stallard, in his work on "London Pauperism," says: That the mortality among Jewish children from 1 to 5 years of age is only 10 per cent., while among the Christians it is 14 per cent. The average duration of life of the Christian in London is 37 years; of the Jew, 49 years.—Extract in *Phila. Med. Times*, Dec., 1872, p. 178.

Deaths among 100,000 individuals:—

Mortality.	Christians.	Jews.
Still-born	143	89
Under 1 year	697	459
1 to 5 years	477	386
5 to 14	202	151
14 to 25	155	123
25 to 45	334	231
45 to 70	614	392
70 and above	239	330
All ages	2,961	2,161

Of 100,000 children:—

	Christians.	Jews.
Still-born	3,569	2,524
Under 1 year of age	17,413	12,935

M. Mayer, in his treatise* relative to the duration of life in the Jewish population compared with that of the Christian, found the following facts connected with the statistics of Fürth for a period of 10 years:—

MEAN AVERAGE DURATION OF LIFE.

Jews, 37 years; Christians, 26 years; excess in favor of Jews, 11 years.

From one to five years old, Jews lose 10 in 100, Christians 14 in 100. This difference holds to the 60th year, but then the difference changes in favor of Christians. From 60 to 70 years, Jews lose 9.8 in 100, Christians 12 in 100; 70 to 80, 8.9 in 100 Christians, 7 in 100 Jews; 80 to 90 yrs., 2.4 Christians in 100, and 8.1 Jews. This result, he says, is not astonishing, since of those who pass 60 years, more individuals of the Jewish race than Christians are living. Among the Christians one-half die before 30 years, while one-half of Jews live to 50 yrs. In France, Dr. Neufville has reached analogous results.

The mean general mortality is	37 yrs.	7 mos.	
Christians, " " "	36 "	11 "	
Jews, " " "	48 "	9 "	

In the first five years of life, of 100 children of Jews, 12.9 die; of 100 children of Christians, 24.1 die. Among 100 Christians, 38.1 attain to 50 years, and 54 among Jews. 13.4 Christians attain to 70 years, while 27.4 Jews attain the same age. One-quarter of Christians attain only 6 yrs. 11 mos., and one-quarter of all Jews 28 yrs. 3 mos. One-half of all Christians die at 36 yrs; Jews, 53 yrs. 1 mo. There is only one-quarter of the Christian population of Frankfort living, above 59 yrs. 10 mos., while among Jews one-quarter pass 70 yrs. Dr. Neufville explains these differences by the following circumstances. There are no proletaires among the Jews, while one-tenth of the Christians live on public charity. Most Jews are in commerce or letters, very few are laborers. Among 100 commercials above 20 yrs. of age, the one-half of the Christians succumb before 57 yrs.; one-half of Jews before 67 years only.

It is in this longevity that the Jews increase more than Christians, and not in marriages and births. In Prussia the Jewish population (1822–1840) increased 34½ per cent., while in the same lapse of time Christians augmented only 28 per cent., increase by immigration being about the same. There was one birth to every 28 Jews, 1 to every 25 Christians; 1 marriage among every 139 Jews, 1 among 112 Christians; 1 death among 40 Jews, 1 in 34 Christians.

Increase in population among 100,000 individuals:

	Christians.	Jews.
Marriages	893	719
Births	4,001	3,546
Deaths, still-births included	2,961	2,161
Excess of births over deaths,	1,040	1,385

According to Lévy, in a mortuary table brought to 1,000, and which embraced a period of 23 years (1833 to 1855), Dr. Glatter compared the following named races with the Israelites, with the result annexed.

	Mean Duration of Life.	Probable Duration of Life.	Among 1,000 Deceden's, No. living from 50 to 100 years of age.
Germans	28.50	21.30	86.7
Hungarians	23.11	10.10	54.4
Croats	22.10	4.80	70.6
Jews	30.20	22.30	120.9

SUICIDE.—Statistics show that Jews commit suicide much less frequently than other religionists, as the following table from Lévy (out of Legoyt) will show.

Among 1,000,000 inhabitants the following numbers commit suicide in each class:—

Country.	Protestants.	Catholics.	Other Christians.	Jews.
Prussia	159.9	49.6	130.8	46.1
Bavaria	135.4	49.1	—	165.9
Wurtemburg	113.5	77.9	—	65.6
Austria	79.5	51.3	54.0	20.7
Hungary	54.4	32.8	12.3	17.6
Transylvania	73.6	113.2	20.5	35.5

The only country in which suicide is more frequent among the Jews than the Catholics and Protestants is Bavaria, and even here M. Legoyt says that in the Palatinate, where the Jews are more numerous, they number fewer suicides proportionally than among the Catholics.

INSANITY.—M. Lévy says—"We associate with suicide, mental alienation; the example of the Israelites seems to contradict this idea, for with the minimum of suicides, statistics impute to them the maximum of *aliénés*."

CRIMINALITY.—The Prussian judiciary statistics, as those of other countries, signal in the Israelites fewer infractions of the penal code than in the Christians:

		1857.	1858.	1861.
Inhabitants for 1 accused	Jews	172	138	150
	Christians	111	117	129

INFANTICIDE AND ABORTION.—I have not met with any comparison of the relative frequency of infanticide and abortion among Jews, as compared with other religionists, but am persuaded that they are, as a race,

* Ueber die Lebenserwartung der Israelitischen Bevölkerung gegenüber der Christlichen. Deutsche Zeitschr. f. d. Statistik, t. xxi, p. 2, 863.

freer from these iniquities than any other people. Protestant clergymen * and physicians † have shown that these crimes are much more frequent among Protestants than among Catholics in New England.

Illegitimacy.—They have fewer illegitimate children; the *Tabellen für* 1849 indicates the total number of births for one illegitimate birth:—

Years.	Evangelists.	Catholics.	Jews.
1831	11.27	16.48	54.21
1834	10.97	16.05	54.68
1837	11.32	16.76	45.78
1840	11.57	16.73	47.61
1843	10.92	16.43	47.07
1846	10.87	16.09	43.83
1849	10.78	16.35	40.09
Average.	11.10	16.40	47.59

Chastity.—The fact of the Catholic women having nearly three times as many illegitimate children as the Jewish, indicates that the Jewish *women* are three times as chaste, and more than four times as chaste as female "Evangelists." This fact by no means warrants us in attributing to Jewish *men* a chastity equal to that of their women, for I am convinced that Catholic men are very far below their sisters in chastity. It is universally conceded that Irish women (particularly Romanists) are, as a nation, more chaste than any other, while the Jews (women in particular) are more chaste than any other race. The writer would venture to suggest that the chastity of the Irish women is principally to be attributed to the almost universal influence of the Church of Rome, probably through the influence of sacramental "auricular" confession, while the traditional shame of illegitimacy among the Jews keeps up their standard of chastity.

The influence of religions on chastity is very noticeable in Great Britain; the Catholics (Irish) being most chaste, the Anglicans (English) coming next, while the Protestants (Scotch) are least chaste of all. It is true that race here may have some influence, but I am fully persuaded that the prevailing religions are in some degree responsible for those differences in degrees of chastity. James Parton, the historian, says ‡ of the Jews: "At the present hour they are probably the chastest seven millions of people under the sun."

Still-Births.—The same authority (Legoyt) says, they have fewer still-births, that is to say, infants who succumb before, during, or a little after labor; the proportion is for them 1 in 39.5 births, while it is 1 in about 30 in the Christians (Hoffmann, period 1823 to 1840). In 1849, M. Legoyt notes 1 still-birth among

	Evangelists.	Catholics.	Jews.
Legitimate births,	24.61	27.24	71.32
Illegitimate births,	17.86	20.05	26.43

Glatter (loc. cit.) gives 1 still-birth in 19 among Christians, and 1 in 34 among Jews.

	Christians.	Jews.
Still-born in Prussia in 100,000 inhab.	143	89
" " among 100,000 child.	3,569	2,524

Infant Mortality.—According to Lévy, (p. 18) the Jews lose fewer children than other religionists; from 1859 to 1861, we find in Prussia, for 100 births the proportions of mortality which follow:

Evangel's.	Cath.	Philipos.	Ger. Cath.	Mennoni's.	Jews.
66.37	65.94	56.04	56.77	86.66	48.11

· *Our Israelitish Brethren*, Atlantic Monthly, Oct. 1870. pp. 358–403.

* Rev. John Todd. Serpents in the Dove's Nest.
† Dr. Horatio R. Storer. Is it I, etc. Boston.
‡ James Parton. *Our Israelitish Brethren.* Atlantic Monthly, Oct. 1870. pp. 358–403.

Causes of Longevity.—Besides physical causes of longevity already mentioned, there are others which may have some weight in this direction. Among these, the fact of Jews being obliged to keep two Sundays in a week, besides Jewish, Christian, and political holidays, or two out of every five days being lost to business, gives them by necessity about twice as many days of leisure as Christians. They do not engage in mining, mechanics, and other hazardous occupations. The biblical and traditional prohibition of certain aliments is favorable to longevity. The fifth and last of the summary of causes to which M. Legoyt attributes the greater mean average duration of life of this people, is "the *sentiment de la famille*, more developed in them than in Christians, assures to their children, to their aged and infirm parents, a solicitude more active; to the new-born the mother's nursing; to the poor an assistance more efficacious. Their charity is unequalled; their morality is demonstrated by judiciary statistics; the firmness and serenity of spirit are the most marked traits of their character, and proceed from a profound faith, from an unalterable confidence in Providence." They rarely use alcoholic liquors and almost never to excess; this is universally conceded. They seldom marry out of their own race, and have little hereditary disease.

Parton, who quotes from the organ of the London Society for the Conversion of Jews, which spends $250,000 annually "in converting (?) a few poverty-stricken wretches, and sending abroad on highly interesting tours a few plausible renegades," confesses: "As to their moral qualities, the evidence seems to show that the lower class of Jews are decidedly superior to the same class among ourselves. They are far less given to drinking; their religious customs enforce a certain amount of cleanliness, both personal and in their dwellings; and two families are never found inhabiting the same apartment."

Among the conditions unfavorable to longevity, we may mention their almost universal habit of residence in large cities, and the rarity of their engagement in agricultural pursuits.

Dr. Glatter concludes from all this that, under the relation of duration of life, the Jews are in a condition much more advantageous than Christians. In effect, the more the mean duration of life augments in a people, as is the case with the Jews, the more it diminishes the number of widows and orphans; the more numerous the active and productive class, the more it diminishes the class of pure consumers.

It is evident from all we have here shown, that the numerical increase of a race depends more on the conservation of those already born than in a great fecundity with less conservation of the issue.

The Jews have always taken every precaution to preserve the life of every individual born.

The Mosaic laws prescribe most of these measures,—even to the construction of their houses, requiring balustrades about the roofs to keep children from falling from them. Ancient Rome, with all the jealous care she exercised in the conservation of her citizens, did not approach the excellence of the Mosaic dispensation of these matters.

Jewish subjects would therefore appear to be much more advantageous risks for life companies than other races.

Note.—It is quite remarkable that Haller, with all his sagacity, should not have mentioned the Jews, in his study of the longevity of different races and nationalities.—Elementa Physiol. Corporis humani, t. viii. 2d edit. Lausannæ, 1778. L. xxx. sect. iii.

The author regrets not having been able to gain access to Prof. Stowe's lectures on Jewish Longevity, delivered at Hartford some years since.

2003 Walnut st., Philadelphia, April 9th, 1873.

PERSONAL HABITS.

By EDWARD W. LAMBERT, M.D.,

NEW YORK CITY.

It is not an easy matter to pass a correct judgment upon the insurability of an applicant by reading the application, even when the utmost confidence is imposed in the integrity of the agent, and in the professional skill of the medical examiner. The difficulty increases when the questions are answered in a general and indefinite manner. No question presents more difficulties than that relating to the personal habits of the applicant. As a rule this question is answered more indefinitely than any other in the application: yet this is *the question*, of all others, which will give the most information as to the probable longevity of the individual, and it ought to be answered so definitely and clearly, that he who reads may correctly understand the manner of the daily life of the applicant.

The word temperate ought to be used in its broadest sense, referring to the quantity and quality of food taken, as well as to the kind and quantity of fluid used by the individual in question.

A strictly temperate man is one who "eats neither too much nor too little, who uses plain and wholesome food," and who proportions his food to his temperament, his age, and his vocation, and who uses alcoholic stimulants and malt liquors medicinally, not as a beverage. It is admitted few applicants fill the above standard, but the nearer any one approaches it, the more likely will he be to live out his expectation of life.

The question of temperance in eating is not sufficiently regarded, yet, according to the recent mortality tables of England, more men at the present day die early from excessive indulgence in eating, than from the excessive use of alcoholic stimulants.

In order to give an approximate idea of the personal habits of applicants for life insurance, it would be wise to divide all persons of the same age into four equal classes, putting each individual into that class with which his personal indulgence places him.

Class I. will include those who are careful eaters, and total abstainers from alcoholic stimulants and malt liquors, or who use the latter medicinally.

Class II. will include those who use wine and malt liquors at dinner, who may occasionally indulge in food to excess, but who, as a rule, are as careful in their indulgence as Class I.

Class III. will include those who are steady but moderate users of alcoholic stimulants, who are fond of the pleasures of the table, yet no one can say they are ever overcome by their appetites. This is the doubtful class, and it is a very deceptive one to life insurance companies.

The steady and moderate drinker of to-day may become, and too often does become, the drunkard of a few years hence. Many do not live long enough to carry their indulgence to excess, but die early from some acute disease, such as pneumonia, &c., simply on account of the continued use of alcoholic stimulants.

Class IV. will include all those who are known to be given to excessive indulgence.

There is another class of individuals concerning whom it is extremely difficult to decide with justice to them and to the company, namely, those who have used alcoholic stimulants to excess, but who have become total abstainers.

The length of time since the reformation ought to be distinctly given. The extent to which the indulgence was carried ought to be definitely stated. If the reformed individual has ever had *mania à potu*, it is useless to examine such an one, as it is an almost universal rule that such a person will eventually return to his old habit, and die in consequence of his excessive use of alcoholic stimulants. The age at which the reformation takes place, and the present social position of the individual, have much to do with the probable continuance of the good resolution.

This subject is by no means exhausted, but enough has been said to call the attention of medical examiners to the fact, that they cannot be too minute in giving an account of the personal habits of applicants for life insurance.

ON THE RELATION OF THE MEDICAL EXAMINER TO THE BUSINESS OF LIFE INSURANCE.

BY THE SECRETARY OF A LIFE INSURANCE COMPANY.

The writer of this article has found by actual inquiry that the opinion very generally prevails amongst life underwriters, that from one-third to one-half of the risks accepted by them as sound, would never have been underwritten, were it possible to have had the applicants in all cases brought to the head offices of the companies, to undergo inspection by the officers and examination by the medical directors, supposing these to have the same knowledge of the habits and surroundings of the applicants as is generally possessed by the local medical examiner and agent. Indeed one officer of a prominent company, to whom the writer applied for information upon this point, gave it as his opinion that, judging from the results in his own company, the object of a medical examination appeared to be, not so much the selection of *good* lives, as to see how *bad* lives could be *squeezed in*. Whether these estimates be correct or not, it is undoubtedly the fact that by all life underwriters the medical examination is considered the *weak spot* in conducting the business of life insurance; or, in other words, that the medical examination of applicants does not afford that protection against the intrusion of unsound lives which it is designed to effect, and which it would effect, if honestly and efficiently performed. Moreover, it must be stated that this opinion of the medical examination as an element in the conduct of the business, does not result so much from a want of confidence in the professional skill of the examiners, as from the absence, too frequently observable, of a certain *moral* qualification, not less essential in the exercise of his responsible duties.

In many cases, more particularly in the country districts, the examiner on the part of the life insurance company is also the family or attending physician of the applicant for assurance. In such cases the physician, if he is a man of honor, will decline to act for the company, or to receive its fee, if a feeling of loyalty to his friend and patron in the least degree interferes with his perfect freedom of judgment in performing the duties expected of him by the company. Even where the relation alluded to does not exist, it is frequently found that a neighborly feeling towards the applicant, or lack of sympathy with the company, consequent upon entire unacquaintance and non-intercourse with its managers, or mayhap through a friendly feeling towards the agent, the company's interests are sacrificed in not obtaining that full information regarding the "health, habits and circumstances" of the applicant, no less necessary to a correct estimate of the risk submitted, than an accurate statement of a careful physical exploration.

It is this want of thorough personal independence,

and lack of sympathy with the views and objects of the underwriters, far more than deficiency in professional ability in those assuming the duties of medical examiners, that is most dreaded by those engaged in conducting the business of life insurance.

The companies have suffered considerably from this cause, and hence the unfavorable impressions entertained in the majority of the offices as to the value of a medical examination.

The existence of this feeling amongst the fraternity of life underwriters is, in the opinion of the writer, matter for grave consideration by the members of the medical profession. He believes that the mortuary experience of the life insurance companies should be a subject of much interest, even solicitude, to the members of that profession. It is not unfair to consider *that* experience in some degree a measure of the ability and integrity displayed by them in their rôle as examiners. All honorable members of the profession have, therefore, a direct interest in protecting the life insurance companies from the losses incident to the incapacity or want of fidelity to the trust reposed in them of some of its members, and should, through *esprit de corps*, if not from purer and more honorable considerations, lend their aid in so doing.

In the careful selection of risks the executive officers of the companies are compelled to depend largely upon the honor and good judgment of the local medical examiners, no less than on their professional skill, aided, as the latter are, in the majority of instances, by their *personal* knowledge of the general health, habits, and local reputation of those proposed for assurance. In judging of the desirability of risks they have immense advantages in this respect, advantages which they are bound, as men of honor and integrity, to use for the benefit of the company whose trusted representatives they are.

The officers of life insurance companies reasonably expect that the physicians whom they employ, and who accept their fee, will be in full accord and sympathy with them; and that they will act and advise with entire independence of all local feeling and influence, no less than with an intelligent understanding of the great influence their decisons exert upon the working out of one of the most beneficent schemes yet devised for the amelioration of the social suffering and embarrassment too often consequent to widows and orphans when death removes their natural protector.

The officers of life insurance companies do not consider that the medical examiner performs his whole duty by giving laconical categorical answers to the printed questions in the certificate prepared for him. Considering him as their trusted and confidential local representative, they desire that his report should not be merely that of the professional expert, but that he should take an interested and *business-like* view of each case submitted to him; permitting his judgment and advice to be freely influenced by the consideration of the important *financial* bearing of his decision. They expect that he will consider the interest of the company for which he acts as paramount to all others, and "resolutely stand like an alert and faithful sentinel, between the company on the one hand, and the unsafe and undesirable risk seeking admission thereto, on the other."

The examining physician is a chief controlling power in the safe conduct of the business of life insurance. Upon his skill, fidelity and independence depends largely the prosperity or even safety of the company for which he acts. Carelessness, incompetency or want of fidelity to his company on the part of the examiner, may injuriously affect the vital interests of thousands of innocent persons. This, surely, is a serious consideration, and should profoundly impress him with the almost sacred trust reposed in his personal honor, no less than in his professional skill.

ON THE LAW OF MORTALITY THAT HAS PREVAILED AMONG THE FORMER MEMBERS OF THE DIVINITY SCHOOL OF YALE COLLEGE.

By PROFESSOR H. A. NEWTON,

YALE COLLEGE.*

A CATALOGUE and biographical record of the persons who have been members of the Divinity School of Yale College, during the fifty years of its existence, from 1822 to 1872, has just been prepared and published by Prof. George E. Day. The materials for the record have been collected with very unusual care, being in almost every case from autograph letters, or other authentic documents. This fact, as well as various other peculiarities of these statistics, make it worth while to look at them with special reference to the vital experience of the persons named in the catalogue.

By the *law of mortality* of a community, or of a large selected group of persons, is usually understood the varying probability of death in that community, or group, for the different *ages* of the members. Thus out of a thousand persons aged thirty, we find that in one year there will be in the mean 8 or 10 deaths; of a thousand aged fifty, there will be from 14 to 19 deaths; of a thousand aged seventy, there will be 60 to 70 deaths. These numbers of deaths for each age of life, accurately found for a community and put in table, express the *law of mortality* for that community.

The law of mortality is not the same for all groups of men. It varies with residence, with occupation, with sex, and with other causes. The law for assured lives is different from that of annuitants; that of scholars differs from that of laborers; that of the clergy from that of lawyers or doctors. The law deduced from observation in one year, might be expected to vary from that of another year, if the prevailing diseases differ. The law for American lives must differ to some extent from that for English lives, and both differ from that for German or French lives. Such differences, of course, though real, are often quite small.

The graduates of this Divinity School form a class in some respect peculiar to themselves. Most of them are preachers, and the larger part of the rest are teachers, or are at other work in which the risks of disease and death are like those in the ministry. The effect of care and forethought in prolonging life is nearly the same for them all. The medical selection of assured lives has given a peculiar character to all the tables deduced from the experience of insurance companies, but from such an effect the statistics of this catalogue are nearly free. Although, therefore, the number of years of experience is not large, being less than 20,000, and the number of deaths less than 200, it seems worth while to see what evidence they furnish about the law of mortality among such lives in our country.

* The original article appeared in the April number of the *New Englander*, a quarterly journal published in New Haven, Conn. As very few of those interested in the subject will be likely to see the *New Englander*, we have reprinted the article in the form of a pretty full extract.

In the treatment of the data I have proceeded as follows: each person who has belonged to the school is regarded as coming under view on the day of Yale College Commencement of the year in which his class finished its course. The risk (to use a technical term) begins on that day, and his name continues on the list until the anniversary of that commencement next following his death, if he is dead, or till that day in 1872 if he was then living. By this rule the students who die while in the seminary, that is before the Commencement of the year of graduation of their class, are thrown out of our account. Against this, of course, are thrown out also the years of favorable experience of the students who survive. Each name belongs in the group an exact number of years.

It was assumed also that the Commencement day named is to each person his birthday, and that the completed year of his age on that day is the age attained upon the *nearest* birthday, before or after. That age was written opposite each man's name in a copy of the catalogue. Along with this was also written the age just attained on the corresponding day of 1872, if he was then living; and if dead, the number of the *unfinished* year of age, the birthday being assumed as before.

If the statistics had been complete, this process would give us the means of getting completely the vital experience. How shall we treat the cases where the facts are not all given? We cannot throw out such names, for these records are in many cases incomplete *because* of the death of the persons, and in other cases we know about a man *because* some one has written an obituary notice of him. It is better to retain all cases in which we can assume without serious error the dates and ages needed to make the data complete. Thus for three or four persons the year of birth without the day is given. For thirteen persons the age is obtained from the matriculation records of Yale College. Six persons, who are doubtless living, were last heard from in 1870 and 1871. The risk upon their lives ceases with those years. One person is reported dead, but the year is unknown, and I assume that he lived half of the time from graduation till 1872. Five deaths are reported in given years, but the month and day are not told. For them, the first of January is made the assumed birthday, and fractions therefore appear in the columns of the deduced tables. In one important case the death occurred in the year of graduation, whether before or after commencement is not known. I have added a fraction (0.36) in the years of risk, and a like fraction in the column of deaths.

Of 41 persons the birth year is not known. The average of 771 known ages, at the time of finishing seminary studies, is 27.7 years. The remaining 41 persons are without doubt older, as many of the persons are reluctant to tell their ages. I believe the error will not be large if I assume them to have been on an average 29 years old.

There are seventeen persons of whom we have no recent satisfactory information. Six of them have been heard from at an average of more than 10 years after graduation. This group, about two per cent. of the members in the catalogue, I have left out entirely. Perhaps we have not heard from them because they are dead; perhaps because they are not dead. To balance any greater chances of the former kind may be set off their sixty-three years of known favorable experience. If the experience of these seventeen persons can be learned, and if it shall prove to have been more or less favorable than that of the rest of the graduates, the following conclusions will need correction by about two per cent. of the difference.

In Prof. Day's catalogue there are 854 names. Eight died before finishing their studies, seventeen are not heard from, and seventeen were of the class of 1872. This leaves 812 persons, of whom 771 were of known ages, and 41 of an assumed age.

[Prof. Newton then compares the mortuary experience of these 812 former members of the Yale Divinity School with the experience of 20 English Life Assurance Companies, and shows the results in the following condensed table.—Ed.]

Ages.	No. of years of risk.	Expected mortality.	Actual mortality.
21—26	333.4	2.5	2.
26—31	2281.	17.8	25.
31—36	3439.66	29.1	28.36
36—41	3182.3	30.5	30.
41—46	2867.4	32.5	23.6
46—51	2472.4	34.8	17.4
51—56	1960.	36.0	17.
56—61	1311.8	32.9	29.
61—66	690.	24.9	13.
66—71	292.	15.0	8.
71—79	83.	6.4	4.
Total,	18912.96	262.4	197.36

Up to an age between 40 and 45, the total expected and actual mortality are equal. Above that age the actual mortality is about three-fifths of the expected.

It should perhaps be noticed in passing, that the standard table was made from all assured lives, that the benefits of medical selection in the early years were not eliminated, and that therefore the table to that extent does not express the law for common lives. The only fact that implies a corresponding influence of *selection* in the group of lives we have been considering, is that each person had health enough at some time during the three years before entering the group to begin seminary studies. Other causes, I think, belong to the law of mortality of the group.

That mortality among the clergy was less than among men of equal ages in other occupations has been well known. Mr. Neison, in a very important and interesting article upon the influence of occupation upon health, as shown by the mortality experienced in England and Wales in 1860 and 1861, gives the following percentages of mortality per annum for males in the classes and occupations named. I select a few among similar figures:

	Ages, 25—65.	25—45.	45—65.
Total population	1.50	1.05	2.30
Coal Miners	1.48	1.10	1.82
Copper miners	2.47	1.40	3.17
Blacksmiths	1.38	95	1.61
Butchers	1.74	1.20	1.98
Beer Sellers, Wine Merch'ts, Innkeepers	2.44	1.70	3.32
Clerical profession	1.04	52	1.72
Legal "	1.51	91	2.24
Medical "	1.77	1.28	2.35

To discuss causes is outside my purpose. I close with one remark upon a money aspect of the subject. The law of mortality among the clergy is probably such that the actual cost of life insurance is less for them than for men in other occupations. If the exact amount of the difference can be shown they are justly entitled to the benefit of it, and the insurance companies would undoubtedly in some way give it to

them. But before the companies can justly make such a concession, the law of mortality for the profession among the several denominations in this country must be better known than at present. Is it not worth while for the clergy to collect the facts needed to make such a table of mortality.

IMPERFECT REPORTS OF MEDICAL EXAMINERS.

BY A MEDICAL DIRECTOR.

One of the principal difficulties which the Medical Director of a Life Insurance Company meets with in the discharge of his duties, is the lack of clearness and precision in the returns of the medical examiners. If a little more attention were given to these points during the examination, the character of the risk might be determined at once in the home office and a vast expenditure of time and labor saved. Every day these imperfect reports are received by the company only to be returned by the next mail for further and more satisfactory information. There is no part, however, of the examiner's report where the information is usually so unsatisfactory as that relating to the family history. In this connection we would venture to state that the companies themselves are in many instances to blame. Their examiner's blanks are worded in such a way that a careless or even a moderately careful physician may very readily convey wrong impressions to the home office. In many of these printed forms the question of family history is provided for with great care in the application, but in the examiner's report the simple question, "Is there any hereditary taint in the applicant's family history?" is regarded as amply sufficient. If the physician is fully alive to the responsibility of his position, this simple question will suffice, for it will lead him to cross-examine the applicant thoroughly in regard to the diseases that have carried off parents, brothers or sisters, or are still afflicting them. Many physicians, however, will simply ask the applicant whether any case of consumption, scrofula, cancer or insanity has ever occurred in his family, and will rest satisfied with an answer in the negative. We are satisfied from experience that in many cases this negative answer will fail to convey the truth to the home office. The applicant, who probably knows nothing about medicine, repeats exactly what the attending physician has told the family. When asked, for example, what his father and mother died of, he may say in the one case "fever," and in the other "childbirth," which for him are two good and sufficient causes. The applicant is perhaps a perfectly honest man, and may have no suspicion that there is anything wrong about his family history. A little further questioning is then done by the physician, and the facts are elicited that the father had been suffering for several months from "asthma and general debility," and finally died with what the attending physician called a "fever." The mother lingered on for three or four months after the birth of the child, gradually losing her strength, and finally died from the effects of "childbirth." To the medical director these few facts seem to point clearly to consumption as the real cause of death of both parents, and he accordingly rejects the applicant, whom the medical examiner describes as personally a first-class risk. In the same way "lung fever," "pleurisy," and similar expressions often prove to be synonymous with consumption.

We have no radical remedy to offer for this trouble, but would simply suggest that instead of relying for the family history upon the statements in the application, the companies should look to their medical examiners for these details, which can only be correctly determined by a professional man. The subjoined blank, incorporated into the medical examiner's report, would perhaps serve to furnish the home office with more correct information than they now receive and would spare them much needless work.

FAMILY HISTORY.

	Age, if living.	Condition of health.	Age at death.	Disease.	How long sick.	Previous health.

Original Lectures.

ON ATROPINE.

A LECTURE DELIVERED AT THE WOMAN'S COLLEGE OF THE N. Y. INFIRMARY.

By MARY C. PUTNAM, M.D.,

LECTURER ON MATERIA MEDICA AND THERAPEUTICS.

PART I.

LADIES:—In inaugurating this year's course of lectures, I must first point out to you a certain change that I have made in our programme;—a change which will cause it to differ materially from that of corresponding courses delivered at other schools in this city.

Last year, imitating the system that I believe generally prevails in this country, the lectures on Materia Medica and Therapeutics were combined, and both attended by all the students, whether these had been studying one, two, or three years. On this account, students at the very outset of their career were compelled to listen to accounts of the remedial action of drugs, that their ignorance of pathology rendered completely unintelligible to them; and, on the other hand, others, preparing to graduate, were obliged to review details in the chemical and pharmaceutical history of medicines, when these, in comparison with the urgent interest offered by their therapeutical properties, could not but seem dull and unimportant. Moreover, such students, having passed through no preliminary training, were plunged immediately into one of the most complex and difficult studies in the entire range of human sciences—that of the action of drugs on the living organism in health and disease. A science that requires as basis a minute and comprehensive knowledge of physiology and pathology, was thus attacked by persons who as yet were only furnished with the most slender modicum of such knowledge. As a necessary consequence, the true complexity of the subject was ignored, and knowledge of the action of drugs resumed in a few bald formulæ, whose simplicity, no less than their rigidity, rendered them entirely insufficient as guides in the labyrinth of therapeutical problems.

As such system of instruction was illogical, I have not hesitated to set it aside, though supported by so much example and precedent. This year, therefore, the course will be divided into two distinct sections. The first year students will be invited to the study of materia medica; to familiarize themselves with the properties of drugs in their natural and commercial condition; afterwards to trace them through their various pharmaceutical preparations, many of which they will have an opportunity of fabricating themselves. They will learn the origin, the botanical and chemical classification, the chemical constitution and physico-chemical properties of drugs, before attempting to rise to the contemplation of their properties in relation to vital organisms. By this means they will thus: 1st, acquire certain knowledge which otherwise they are only assumed to possess; 2d, be trained for the acquisition of other knowledge which they must in great measure miss, if they have not been previously prepared to receive it by exercise in simpler studies.

The second and third year students will study, in a two years course, the physiological action and therapeutical application of drugs. As far as possible each proposition will be illustrated by experiments made upon animals in our laboratory, or by the treatment of patients selected from our clinics.

I will express the hope that, before long, our school will accept the standard of Europe, and create a chair of materia medica entirely distinct from the chair of therapeutics: that, further, each of the seven primitive chairs will be divided into an elementary and an advanced section. Until this is done, *all* medical education will remain elementary, and the very conception of a superior education will continue to be ignored.

. . . . . .

I have selected atropine as the first subject of this year's studies, because the researches that have been made in regard to it afford a complete type of those that should be pursued in regard to every reputed remedial agent. It is necessary, 1st, to observe the succession of phenomena produced by such agent after its introduction in a healthy organism; 2d, to analyze each of these phenomena to its ultimate elements; 3d, to compare the effects of the drug upon organisms involved in various morbid conditions, with the results obtained from such analysis.

In the first place, therefore, we have to consider the general tableau constituted by the physiological effects of atropine . . . . ; and the first phenomenon that demands analysis is the effect of atropine on the pulse.

There is no doubt that atropine accelerates the pulse. But in regard to this acceleration we must ask the following questions:—

1st. Is this acceleration immediate or secondary? According to Harley and Meuriot, the pulse is *immediately* accelerated after the administration of atropine; this acceleration is indeed the first effect produced. According to Schroff, Posner and Nothnagel, the pulse is first lowered, and afterwards accelerated. According to Bezold, the acceleration is immediate after subcutaneous injection, secondary after ingestion of the poison. In Bezold's experiments upon guinea-pigs and dogs, an acceleration of from 14 to 48 beats frequently occurred during the first minute, or even quarter of a minute. In one dog, the pulse rose suddenly from 80 to 240 beats in a minute. In these cases the atropine had been injected into the facial or external jugular vein.

Harley's observations are less reliable, because not made until ten minutes after the injection.

In the three cases where we tested the action of atropine on human beings before your eyes, we observed a fall of the pulse within ten minutes. In the first case the patient was a delicate, lymphatic, but not nervous woman, to whom one-fiftieth gr. of sulph. atropiæ was given by the mouth, the pulse then being at 96, probably from some emotional excitement. In ten minutes the pulse had fallen to 80, and remained at 80 to the end of an hour, notwithstanding the occurrence of other symptoms of atropism, a slight flushing of the face, dryness of mouth and throat, and very slight dilatations of the pupils. In the second case the subject was a rather robust woman in good health. The pulse being at 80, one-fiftieth gr. sulph. atrop. was given by subcutaneous injection. In seven minutes the pulse had fallen to 68. In fifteen minutes came a dryness of the throat and slight giddiness. In twenty minutes the pulse had risen to 104. This rise may have occurred at fifteen minutes, as at that time the pulse was not examined. In the third case, after hypodermic injection of $\frac{1}{50}$ grain, the pulse fell in five minutes from 92 to 80, in 10 minutes rose to 100, in 20, to 104.

You see, therefore, that both these cases contradict Bezold's statement, that the acceleration is *always* immediate after subcutaneous injection, and always secondary after ingestion; for in the cases of injection the acceleration, which was notable, was pre-

ceded by a marked diminution, and in the case of ingestion the pulse fell, and did not again rise. But in this case the subject belonged to a class that we shall find, for reasons to be hereafter noticed, is rather insusceptible to the action of atropine, and therefore the dose was too small. The other cases, on the other hand, fairly represent habitual conditions. This initial fall of the pulse is more certain to occur in human beings than in dogs, whose cardiac susceptibility to atropine is very great. It is also to be expected from subcutaneous injection rather than from an injection into veins. This phenomenon is too transitory to be of any value therapeutically, but physiologically it is extremely interesting, in connection with another atropine effect of which we shall presently speak,—I mean the contraction of the small arteries.

2d. At what doses does atropine determine an acceleration of the pulse?

On this point there is unanimous testimony. The heart's action is accelerated by *small* doses, and slackened, on the contrary, by large. In guinea-pigs, from 0.0005 to 0.02 accelerated the heart from 4 to 12 beats in 15″; while 0.05 lowered the pulse in one case from 70 to 44, in another from 80 to 58. With 0.10 the pulse first slackened, then stopped in about a minute (Bezold).* In the horse, with one-twelfth of a grain, there was acceleration of the pulse 10 beats in 35 minutes; with one-sixth, acceleration of 24 beats in 17 minutes; with ¼, acceleration of 56 in 12 minutes: and this was the maximum acceleration obtained. With ½ grain it was 42 beats in 12 minutes, and with 2 grains 35 in 15, or 37 in 20. Similarly on the dog, with $\frac{1}{100}$ grain pulse rose from 120 to 300 in 14 minutes; and $\frac{1}{50}$ and $\frac{1}{25}$ grain produced the same effect; but with $\frac{1}{10}$ the pulse was 400 at the end of 1½ hours. In man there is said to be an acceleration of 20 to 25 beats with $\frac{1}{120}$ or $\frac{1}{90}$ grain; 20–60 beats with $\frac{1}{60}$ grain, 20–70 with $\frac{1}{40}$, and only 30 with $\frac{1}{20}$ of a grain (Harley).† Meuriot noticed an acceleration of 84 beats in 90 minutes after an injection of 0.001. Nevertheless, with toxic doses, the pulse remains extremely frequent until an advanced period of the coma. In Behier's case,‡ where an old man of 75 had taken 0.013 of sulph. atropiæ, the pulse was 108 in three hours, at the beginning of profound coma, and rose afterwards and beat at 120 all night, and until return of consciousness. In a case quoted in *Amer. Jour. Med. Sciences* for 1866, from Schmid,§ after ingestion of ¼ grain of atropia, and during period of excitement, the pulse was 130. On the other hand, in the famous case of Dr. Angelo Poma,‖ when a profound coma had set in 2½ hours after the ingestion of f ʒ j. of solution of extract of belladonna, the pulse was extremely slow. In several other cases of poisoning it is recorded that the pulse was weak and depressible, though the number of pulsations is not given. In Lee's cases of poisoning with the analogous mydriatic, stramonium,¶ the pulse was from 100 to 150 in the two men patients, who were comatose when treatment commenced; and 140 in the woman, who was in a state of maniacal excitement resembling delirium tremens. The pulse only sinks immediately and permanently when injected into the jugular vein, a condition that evidently is never reproduced in man.

By ingestion or subcutaneous injection, and after the initial slight fall, the pulse is therefore always accelerated; and this acceleration, though not in exact proportion to variations of physiological doses, is excessive in those doses where it will ultimately or rapidly be succeeded by slackening. (See also Schroff* and Meuriot.†) This fact is important to remember, in interpreting certain details of the reactions of belladonna in cases of opium poisoning. By it we also test the value of the assertion made by Lemaitre,‡ and supported by another, quoted by him from Lensana,§ that the effect of atropine upon the pulse is only slightly appreciable.

3. How is the pressure in the arteries affected during the atropine acceleration of the pulse? Marcy has formulated the following law:—"The frequency of the pulse, or of the cardiac contractions, is in inverse relation to the degree of arterial tension." It has been said, on the other hand,‖ that Ludwig and Thiry have formulated another law, precisely the reverse of this: "The frequency of the pulse increases *with* the arterial tension." In both cases the arterial tension is taken as the point of departure, and its rise or fall declared to be a *cause* of the acceleration of the heart's action. This quotation, however, is not quite incorrect. According to the exposition of Ludwig's views, made in a memoir of Bezold,¶ and also in another of Pokrawsky, after an increase of the blood-pressure, the pulse was sometimes quickened and sometimes slackened. This, whether the increased pressure was determined directly by closure of the cœliac and renal arteries, or indirectly by irritations of the spinal cord or splanchnic nerves. Thus Ranke, who admits that an acceleration of the pulse takes place when the arterial pressure is increased, observes that it occurs likewise when this is diminished, but when the force of the heart is diminished even more rapidly than the resistance in the arteries.**

It is evident that arterial tension may be increased, either when more blood is thrown into the arteries by greater force of the heart's action or when an obstacle exists to its efflux. An agent that, like cold, excites the active contractility of the small arteries, by accelerating the peripheric circulation, necessitates the acceleration of the heart's action. The tension of the blood-vessels rises, but the rise is the consequence, and not the cause, of the quickened pulse. With any condition that weakens at once the blood-vessels and the heart, as fever, or the action of certain narcotics, the tension will be lowered, yet the heart accelerated, while the vessels are passively dilated. Both the acceleration and the lowered tension depend on the insufficiency of the cardiac contractions. With bromide of potassium the small arteries are completely constricted, the tension raised (?), and the pulse lowered. With atropine, the arteries are partially constricted, the tension raised, and the pulse accelerated. Only at the very beginning the pulse falls, and this before any effect has been produced on the small arteries. The acceleration of the pulse coincides with acceleration of the local circulation, from the increased active contractility of the arteries. As this local acceleration is sufficient to compensate the degree of obstacle caused by the constriction, the rise of tension cannot be explained by that, but by the rapidity with which the arterial system is filled.

In Meuriot's experiments upon man with atropine the

ine of ascent in the sphygmographic trace (percussion troke of Mahamed*) remained vertical, but was not so igh as normal. This would indicate that the arterial onicity was increased, while the heart had not lost ny of its vigor. At the same time, the line of descent vas not separated by any appreciable interval from he upper stroke, showing that no obstacle existed to he efflux of blood into the capillaries. This rise in re tension was first noticed in 15 minutes after injection of 0.001. ($\frac{1}{100}$ gr.) and had increased in 30 minutes, the pulse quickening at the same time. In ne observation, where 0.012 were injected and the race taken in 40 minutes, the vertical up-stroke had allen still lower, and there was moreover a rounded ummit, as if with this dose and at this time, the efflux of blood was somewhat obstructed.

When the tension in the carotids was measured in ogs by a hæmometer, the pressure rose with a subutaneous injection of from 0.005 to 0.05 sulph. atroine ($\frac{1}{200}$ to $\frac{1}{10}$ gr.) This was the limit within hich the pulse rose. With injection of 0.10 ($1\frac{1}{2}$ gr.) ne pulse and the arterial pressure fell together.

Similar experiments by Bezold gave similar results. n the cases already mentioned, where the dose administered caused an acceleration of the pulse, it generally caused an increase in the blood pressure also, ut in one case (Guinea-pig) this sank from 92 to 72 illimetres during the injection, and did not recover s original level until 30 minutes after, although the ulse was slightly accelerated. In another, where 0.30 ere injected into the facial vein of a dog, the pulse ose in $\frac{1}{4}$ minute after the injection from 60 to 192; nt the pressure in the carotid sank from 140 to 20. n this curious experiment, the dog was killed by successive doses of atropine (he received in all 0.80);—tificial respiration was practised and the abdomen ened. This operation generally lowers arterial tenon, but in this case it rose to 30 (having sunk to 5), hile the pulse beat 168 times in the minute.

From these experiments it appears, that with moderate acceleration of the pulse during first stage of atropine the pressure rises;—h the excessive acceleration of sudden toxic ses, of coma;—of ultimate paralysis, in a word,—pressure sinks. We think that it may be thence erred, that in atropinism the pulse is not accelerated ause the tension is increased, but that the tension is reased because the pulse is accelerated, the heart at same time retaining its vigor, and thus, in a given e, throwing more blood into the arteries. In the palytic stage the heart contracts as rapidly, but with nt feebleness; at the same time also there is paraic widening of the blood-vessels, so that a double rence exists to lower the tension. These details of special interest, in comparing atropinism with results of section and galvanization of the pneumastric nerve.

h. Thus we see that the heart's action is accelerby atropine in extremely small, *i. e.*, therapeutical s; that this acceleration occurs immediately in , after a slight initial diminution in man, and is mpanied by increased arterial tension. Upon does this acceleration depend? The pulse is acated,—1st, when the muscular fibre of the heart is tly stimulated by a greater afflux of blood, itself mined by increased respiratory movements.

. Similar direct stimulus is felt by the intrac ganglia, controlling the rhythm of the heart's ments.

3. Acceleration also occurs when the cervical sympathetic or cervical spinal cord from which it is given off is galvanized.

It is well known that the modus operandi of this influence is the subject of a famous dispute, to which we have already made allusion. According to Bezold and Pokrawsky,* the influence is direct, and galvanization of the nerve acts immediately upon the muscular fibre of the heart to which it is distributed. According to Ludwig and Thiry, the influence is indirect, and dependent upon variations in arterial tension. Galvanization of the sympathetic or of the cervical cord causes the contraction of whole territories of blood-vessels, even those of the mesentery. This still occurs, when the cord is galvanized, after all the nerves going from it to the heart have been cut, and according to Ludwig, in that case the pulse is still accelerated. But Bezold and Pokrawsky affirm, on the contrary, that in this case the acceleration of the pulse is *much less marked* than when the nerves are intact. The contraction of the blood-vessels still occurs, but the direct stimulation of the heart is wanting. The three observers, however, it is seen, agree in ascribing a certain amount of acceleration of the pulse purely to the rise of arterial tension determined by constriction of the blood-vessels—contrary to the theory of Marey. According to Bezold's theory, if atropine stimulated the sympathetic in the heart, as it does in the small arteries, the heart would be directly accelerated, by stimulation of its accelerating nerves. According to the other theory, any stimulation of the cervical or cardiac sympathetic would merely reinforce that directly exercised upon the blood-vessels by the local contact of atropine. The only way to prove a direct influence upon the sympathetic is to isolate the heart by a section of the pneumogastric, and then administer the atropine. But the acceleration of the pulse after this operation is already so great, that such acceleration as might be produced by stimulation of the sympathetic would be entirely masked. It is certain that when atropine is injected after section of the pneumogastric, the acceleration of the pulse is not further increased.

The constriction of the small arteries sometimes coincides with an accelerated, sometimes with a slackened pulse. Sometimes, as in Ludwig's experiment, where the cervical cord is galvanized after section of the sympathetic nerves going to the heart, this constriction seems to be the only cause of the acceleration of the heart's action, and the acceleration is not very marked. Sometimes, as after administration of bromide of potassium, the small vessels are strongly contracted, but at the same time the pulse falls. The same coincidence is shown in an observation of Pokrawsky's. When carbonic oxide gas was injected into the veins or inhaled, the small arteries, stimulated by blood deficient in oxygen and too rich in carbonic acid, contracted: at the same time, the pulse and tension fell "from coincident irritation of the medulla and vagus."

But the active partial contraction of the small arteries determined by atropine, with increased local circulation, is quite different from the complete contraction caused by bromide of potassium or carbonic oxide or carbonic acid gas. If the blood flows more rapidly at the periphery, the heart must contract more rapidly. Hence in this way the stimulation of the sympathetic produced by atropine would be one cause of the acceleration of the pulse. Whether there is also a direct stimulation of the fibres going to the heart we cannot consider at present as determined.

4th. The most powerful means of acceleration of the

* *Med. Times and Gaz.*, 1872.

* Ueber das Wesen der Kohlenoxyd Vergiftung.—Dubois und Reichert's Archiv, 1866.

heart's action is well known to be section or paralysis of the pneumogastric nerve; after this operation the pulse rises immediately to double and quadruple its previous speed. Now, the remarkable acceleration of the pulse that follows the injection of atropine can only be compared to that determined by section of the pneumogastric. It is also most noticeable in those animals, as dogs, upon whom section of the vagi produces the most marked effect on the pulse. The tension rises after atropine, as after section of the pneumogastric. As already noticed, if the pneumogastric be severed previously to the administration of atropine, the acceleration of the pulse is not further increased, as if the agent upon which the atropine usually acted had been suppressed by the operation. Finally, if the vagus be cut in an animal previously atropinized, galvanization of its peripheral extremity will no longer produce cardiac tetanus. The electrical excitability of the sympathetic remains intact. From these facts, we think the inference * is indeed justified, that atropine accelerates the heart's action, by partially paralyzing the pneumogastric nerve.

At the same dose, however, atropine, as we have seen, has no appreciable effect on the respiration. Hence the main trunk of the pneumogastric nerve cannot be paralyzed, for in that case the respiration would be interfered with in the ordinary manner. Moreover, when the atropine is injected into the carotid, and sent towards the brain, the pulse is at first slackened, until time enough has elapsed for the poison to be distributed throughout the body, and reach the heart. But if it be injected in the jugular vein, the acceleration is immediate, and much more marked than by ordinary subcutaneous injection.

Hence we may infer that the atropine acts upon the cardiac peripheric extremities of the pneumogastric nerve, partially paralyzing them; that this is the first cause of the acceleration of the heart's action. A second is the stimulation of the sympathetic nerve, possibly in the heart, but certainly in the small blood-vessels. The circulation in them is more rapid, blood passes more rapidly to and through the heart, hence directly stimulated to increased activity. This double mechanism is the first in which the action of atropine resembles that of fever. Other similar coincidences are the slight rise of temperature, the slight increase in the excretion of urea, and the diminution of secretions to which we have called your attention.†

. . . . . .

In speaking of the anæsthetic properties of atropine, it is necessary to recall Botkin's experiments,‡ and the inference that this observer draws from them, namely, that atropine primarily paralyzes the motor nerves. These experiments were made upon frogs, and with overwhelmingly large doses, and the influence of diffusion was not taken into account. In order to exclude this cause of error, the vessels and nerves of the frog's leg must be isolated, and a ligature passed round the soft parts so tightly, that the poison, injected under the skin of the other limb, cannot diffuse through the cellular tissue, but can only reach the nerve by the artery. In a limb so prepared, after administration of atropine, the sensibility is diminished, the motility remains intact, while on the other leg, where diffusion has taken place, both are diminished equally.§ If the ligature embrace not only the cellular tissue, but also the artery, no effect on the nerve will follow the injection of atropine. This shows that the poison anæsthetizes the periphery of the nerves, and not their roots or the nervous centres. For in this second case, as in the others, it has full access to these parts, but, by ligature of the artery, fails to reach the periphery of the nerve. No anæsthesia results, though this supervenes as soon as the circulation in the limb is restored.

The peripheric localization of the action of atropine is shown also by another fact. In a limb under the influence of atropine, an electrical current directed to the skin (or the extreme periphery of the sensitive nerves) causes no sensation. If the same current be directed to the trunk of the sciatic, evidence of pain is obtained. Moreover, reflex contractions occur, first in the same leg, afterwards in the opposite limb, showing that the conductibility of the centripetal fibres is intact.

The motor nerves are only indirectly affected; that is, after diminution of the sensibility, there is necessarily diminution of reflex contractions. But at this time, *direct* irritation of the motor trunks produces as strong contractions as in a normal condition.

That the spinal cord is not primitively affected seems shown by the following experiment:—A ligature is passed tightly around the body of a frog, so as to separate the anterior from the posterior limbs. Atropine is then injected under the skin of the anterior half. At first, irritation of any part of the body produces reflex contractions; but as the sensibility of the nerves in the anterior half diminishes, irritation in *this* region remains without response. But irritation of the posterior half still produced contractions in the four limbs. This shows that the excited motor power of the cord has remained intact, for it is the only medium of communication between the part irritated and the parts set in motion.

Upon the voluntary muscular fibre, atropine has even less influence than upon its motor nerves. With the unstriped muscular fibre, however, it is different. We have seen that, by stimulating the vaso-motor nerves, atropine stimulates the contractility of the muscular fibre in the arteries. According to Meuriot and Ormus, in a rabbit killed after administration of a non-toxic dose of atropine, the movements of the intestine, always observed when the abdomen is opened, are exaggerated, and they infer that the muscular fibre is excited by the atropine. Fleming has come to a similar conclusion, from studying the action of atropine on worms. Bezold has observed, on the contrary, that the intestine of the rabbit remains perfectly still, but this is only after very large doses.

In regard to the unstriped muscular fibre of the intestine, as in striped muscle, it is necessary to separate the action of atropine upon muscular fibre from that upon the nerves, and upon two kinds of nerves, the ganglionic and the splanchnic. In this connection Kenchel's experiments are very interesting.* Two cats were selected, similar in size, and in both the splanchnic nerves were cut before their junction with the solar plexus, and below the diaphragm. Then one of the cats was poisoned with 0.005 of atropine. Both animals were then killed, and on opening the abdomen immediately after death, the peristaltic movements of the intestine were observed to be increased. If now, on the cat that had received no atropine, an electrical current were sent through the splanchnic nerve, this peristaltic action is immediately arrested, just as the heart's action is arrested by galvanization

* Meuriot, Bezold, Botkin, loci cit. Conclusion contested by Harley; but it is difficult to see on what grounds. Huseman, on the contrary, indorses this view.

† In a part of the lecture not deemed necessary to quote.

§ Result of personal experiment.

* Schmidt's Jahrbücher, Bd. 143.

of the vagus.* But in the cat that had received atropine, the electrical excitation of the splanchnic produced no effect whatever; the movements continued. The atropine therefore seemed to act on the intestine by stimulating the ganglionic nerves and disseminated ganglia, which provide for the dilatation of vessels; and by paralyzing the splanchnic nerves, which, by tending to contract the blood-vessels, tend to restrain and tonify the contractility of muscular fibre. The opposition is analogous to that between the pneumogastric and the sympathetic in the heart, and the action of atropine is similar in the two cases.

Precise knowledge of the mode of action of atropine upon muscular fibre is especially important for arriving at a true theory of its action on rigid sphincters, where it has been so often employed therapeutically. The usual expression, "Belladonna *relaxes* the sphincters," is extremely vague, and conveys several ideas more or less false, among others, that of *paralysis* of the muscular fibre. I would venture to suggest that a sphincter grown rigid under irritation, *e.g.*, an os uteri during parturition, is, properly speaking, *tetanized*. It is a remarkable fact that tetanic contractions are always the result of a peripheric and consequently reflex irritation,† as is well known clinically, and may be demonstrated experimentally. In a rabbit upon whom I had made a hemi-section of the spinal cord, irritation of the limb on the side opposed to the section determined tetanic contractions in the limb on the same side. But direct irritation of the gray substance of the cord determined *clonic* convulsions in the adjoining muscles and in the limb.

Tetanus is not analogous to normal contractions,‡ but to cadaveric rigidity, which occurs earlier in tetanized muscles than others. In this state the fibre is shortened and broadened, and as it loses its power to contract in proportion to its shortening,§ it really remains passive and motionless, molecular nutrition is arrested, and the coagulation of undecomposed myosine around the fibre is considered by some observers, in tetanus as in permanent death, to concur at least with change of electrical conditions in the preservation of immobility. The whole chain of sequences is broken when the initial irritation is destroyed. The anæsthesia of the peripheric nerves determined by belladonna allays this irritation, arrests the transmission of exaggerated impressions to the spinal cord, and hence the overwhelming motor excitation that had been sent from it. At the same time, by quickening the local circulation the atropine may facilitate the removal of coagulated or waste substances clogging up the substance of the muscle.

. . . . . .

In regard to the mechanism of the mydriasis determined by atropine, you will still frequently hear it ascribed to a "stimulation of the dilating, radiating fibres of the iris." Even Stellwag, after adducing a great many facts that speak in favor of another theory, concludes by ascribing to atropine a double function. On the one hand it paralyzes the motor ocular nerve, but on the other it "stimulates the nerves distributed to the muscular fibre in the dilator papillæ,—and also in the coats of the blood-vessels." * The existence of the dilator is accepted on the authority of Koelliker, Valentin, Merkel; the distribution to it of the sympathetic nerve is inferred from the effects upon the pupil of section or irritation of that nerve.

You know that when this section is made the pupil instantly contracts, and when the peripheric extremity of the severed nerve is galvanized, the pupil dilates again. The contraction of the pupil after section of the sympathetic is supposed to result from paralysis of these fibres, and to the exclusive predominance of the circular fibres controlled by the motor oculi.

Galvanization of the cervical cord produces as much dilatation of the pupil as if the current were directed to the nerve itself. Now galvanization of the cord which is everywhere followed by contraction of blood-vessels, contracts the blood-vessels in the iris as well.† On the other hand, paralysis of the vaso-motor nerves from section of the sympathetic dilatation of blood-vessels in the iris, as in the head where the temperature rises, is followed by visible enlargement of its tissue and diminution of the pupil.

Stellwag insists on many facts that show a constant association between modification of the vascular tissue of the iris, and changes in the diameter of the pupil. Besides the results of galvanization of the cervical cord and of the sympathetic quoted above, he observes that mydriasis is always accompanied by a tumefaction of the ciliary processes, whose size diminishes during myasis. In the first case blood is passed out from the iris, in the second case, it flows back again to it. Ligature of the common carotid is followed immediately by contraction of the pupil,—an effect of the irritation of the brain from sudden anæmia. But the secondary result on the eye is dilatation of the pupil, when the irritative effect has passed away, and the vascular tissue of the iris finds itself emptied. "Did not such mighty authorities speak in favor of a special dilator of the pupil, we should be inclined to believe that the sympathetic was distributed to the walls of blood-vessels only, and that variations in the size of the pupil were due exclusively to variations in their diameter." (Loc. cit. p. 79.)

The *suddenness* with which the pupil contracts after section of the sympathetic shows that an effect of irritation precedes the paralysis of the vessels, which occurs more gradually, though still rapidly. This sudden contraction is due to a reflex irritation of the encephalon, propagated thither by the central extremity of the sympathetic. It is analogous to that which may be determined by any irritation of the brain, especially of the tubercula anadrigemina, or crura cerebelli, or by the ligature of the carotid.

The contraction of the pupil is not determined by opposite but by different influences from that which causes its dilatation; it is to be expected, therefore, that it should be effected by a different apparatus. In all the active physiological functions of the iris, the pupil contracts. For no purposes of vision does it dilate actively; in obscurity, or in vision of distant objects, the dilatation is caused by simple relaxation of the muscular fibre of a sphincter, from which the normal stimulus had been withdrawn. It is in these cases moderate, and not to be compared to the widening determined by atropine, or by galvanization of the cervical sympathetic, an operation which always constricts the blood-vessels, but only occasionally affects the retina. Any such effect that is produced is irritative, and man-

* As galvanization of the splanchnic is known to contract the blood-vessels, and as the exaggerated movement of the intestine is known to be due to the rapid formation of carbonic acid, when the abdominal vessels are exposed to the air, it seems probable that the movements are arrested because the supply of blood to the muscular fibre is suddenly diminished.

† Traumatic tetanus, of course. Strychnia tetanus seems to be of a different nature.

‡ This fact corresponds to that observed by Legros and Onimus, where direct irritation of certain parts of the gray substance increased the convulsive movements in choreic dogs. Also with the clonic convulsions of epilepsy.

§ Brown-Séquard, Journal de Phys., 1859.

* Stellwag. Der Intraoc. Druck. Wien, 1868. P. 93.

† Stellwag. Loc. cit. p. 76.

ifested by flashes of light; hence if the contractility of the iris as a muscular membrane were called into play at all, it should be to diminish the pupil, as it does physiologically whenever the retina is irritated. But the reverse occurs—already a proof that the dilatation does not depend on the muscular elements immediately connected with the physiological functions of the iris, but rather upon its blood-vessels.

Gruenhagen, with less respect for "weighty authorities" than is manifested by Stellwag, entirely denies the existence of muscular dilating fibres in the iris. "The dilating muscle has never been found, only inferred, from a supposed physiological necessity. * * The only fibres that can be isolated from the circumference of the iris are branching fibrillæ, destitute of nuclei, or covered with nuclei evidently belonging to epithelium,—while the fibres of the sphincter are easily separable, ribbon-shaped, and nucleated." * "The arcades, described by Koelliker, are only blood-vessels, as may be perfectly demonstrated by preparations of injected specimens." † "The radiating fibres that immediately surround the sphincter, and which even Koelliker could not trace to the circumference, are merely dependencies of the sphincter: those beyond are elastic tissue."‡

In a word, there is only one kind of contraction of the muscular fibre of the iris, that which contracts the pupil, in obedience to a stimulus derived from the retina or brain, and conveyed by the cerebral nerve, or motor oculi.§ Dilatation of the pupil is never active, but, according to its degree, depends on one of three different causes. 1st, simple relaxation of muscular tonicity, or from absence of stimulus. 2d, contraction of the blood-vessels, from irritation of the sympathetic. 3d, paralysis of the motor oculi; with complete abolition of muscular tonus, and substitution of the retractility of the elastic fibres. From these considerations we may more clearly understand the mechanism of the action of atropine on the pupil.

Harley performed the following experiments to ascertain if atropine affected the sympathetic:— ‖

In the first case the sympathetic was cut, and after the pupil had contracted, atropine was instilled into the eye. Thereupon the pupil dilated, but only partially, not so much as when the sympathetic remained intact. In the second case the dilatation of the pupil was first effected by atropine, and then the nerve was cut.

The dilatation remained unchanged.

This shows that the influence of atropine upon the sympathetic in the phenomenon, though real, is subordinate.

Again, Kuyper[¶] found that when the pupil had been moderately dilated by atropine, excitation of the superior sympathetic ganglion increased the dilatation.

This implies that the atropine acts upon another element in the iris than the sympathetic. The three experiments together show clearly indeed that the atropine acts by paralyzing the motor oculi nerve. For the iris, while under its influence, cannot contract, even though submitted to the reflex irritation caused by section of the sympathetic. The contracting force is annihilated, and this force lies exclusively in the motor oculi. On the other hand, when the sympathetic has been previously divided, the dilatation caused by atropine is less, for two reasons: 1st. The motor oculi nerve is in a state of reflex irritation, and consequently more resistant to paralyzing influences. 2d. The vessels of the iris are dilated, and its tissue turgescent.

Finally, in Kuyper's experiment, the fact that irritation of the sympathetic increased the dilatation already determined by atropine, shows that the operation and the poison have acted upon two different elements, so that their effects can be superposed.

It is only at the beginning of atropinism, however, that the mydriasis is moderate, and hence resembles that which occurs after paralysis or section of the motor oculi. As is well known, the dilatation continually increases until, in extreme cases, the iris is reduced to a mere rim. This excessive dilatation cannot be ascribed to the constriction of the blood-vessels under the influence of atropine, for although that must necessarily take place, in the iris as elsewhere, it is only partial,—is an initial phenomenon, and its effects would be confounded with those of commencing paralysis of the motor oculi. It can only be due to such complete abolition of muscular tonus as must result from the paralysis of the muscular nerve of the iris, the motor oculi. The retractility of the elastic fibres then comes into play, and reduces the size of the iris to its minimum.*

The action of atropine in relation to the two nervous systems present in the iris, cerebral, and sympathetic or spinal, is thus quite analogous to its action in the heart. It completely paralyzes the cerebral nerve, and moderately stimulates the sympathetic.

Another analogy is revealed by the researches of Kenchel on the submaxillary gland. It is known that irritation of the chorda tympani, which, as branch of the facial, represents the cerebral influence in the gland, increases its secretion; whereas, irritation of the sympathetic, by determining a contraction of the blood-vessels, diminishes the secretion. † After injection of atropine, irritation of the chorda tympani was without effect, and a canula inserted into the duct remained dry and empty. The condition was the same as if the chorda tympani had been paralyzed, or the sympathetic irritated, and there is reason to believe that both effects had been produced.

In the iris, heart and submaxillary gland, therefore, the action of atropine is uniform,—it paralyzes the peripheric extremity of the cerebral nerves, and, by stimulating the sympathetic, determines contraction of blood-vessels and acceleration of the local circulation; hence a double and analogous mechanism by which it dilates the iris, accelerates the heart's action, and diminishes the secretion in the submaxillary gland. ‡

* Zeitschrift fur Rationelle Medicin. 1866. Bd. 28, p. 180.

† Ibid., p 184. Through the kindness of Dr. Knapp, I have been able to myself observe these vessels of the iris, with walls whose diameter is at least half that of their cavity.

§ The extremest contraction, as after opium poisoning, is connected with passive turgescence of the blood-vessels of the iris from paralysis.

‖ *Edin. Med. and Surg. Journal*, 1857.

¶ Quoted by Béclard, *Traité de Physiol.*, 1866.

* A familiar example of the effect of the retractility of elastic fibre upon inert muscular fibre may be strikingly seen in the retraction of the uterus of primiparæ after an artificial labor, with complete absence of uterine contractions, yet followed by no hemorrhage; but, on the contrary, the formation of the "*globe rassurant*."

† And which is succeeded, during the rigor mortis, by a moderate contraction of the pupil.

‡ Kenchel's experiments on the splanchnic nerves above quoted, would seem to show an exception to the general action of atropine on the sympathetic. I do not know whether they have been confirmed; I have not yet had an opportunity of verifying them myself.

Original Communications.

A CASE OF SPONTANEOUS UMBILICAL HEMORRHAGE IN THE NEWLY-BORN.

By S. HENRY DESSAU, M.D.,

ONE OF THE ATTENDING PHYSICIANS FOR THE DISEASES OF CHILDREN TO THE N. Y. DISPENSARY, MEMBER OF THE N. Y. COUNTY MEDICAL SOCIETY, ETC.

According to the recent authority of Dr. Ludwig

Grandidier, of Cassel, spontaneous umbilical hemorrhage of the newly-born is an accident of such rare occurrence as to warrant a physician in recording such cases as occur in his practice, for the benefit of scientific investigators into this, as yet, undetermined subject. The great rarity of the accident may be inferred from the fact that, according to Dr. Grandidier, only two cases were seen by Drs. Hooker and Pearing in America, out of 6,889 births, and only one case was seen by Roger, in the Foundling Hospital at Paris, out of 10,000 newly-born children. I therefore add a case more to the number already recorded, which, under the diligent and searching labor of Dr. Grandidier, have amounted to 220 cases, compiled from various American, French, English and German authorities.

James L—— was born at about two o'clock in the morning, October 3d, 1872, after an easy and natural labor of six hours' duration. The mother was a bright mulatto, at the date of confinement in good health, and had previously borne one child, which was living, and, with the exception of being bow-legged, was healthy. The father was a dark-colored negro, of intemperate habits, having a congenital deformity of the left hand, but otherwise healthy. The child, after birth, appeared perfectly healthy, was well-nourished, and weighed seven pounds. Nothing unusual was noticed during the ten days that I attended the mother after delivery, the cord falling off on the fifth or sixth day, and leaving a perfectly healed navel.

On the afternoon of the fifteenth day I was called to see the child, and was told that it had been steadily bleeding from the umbilicus since the early part of the afternoon of the day before, a period of about twenty-six hours. The cause of the hemorrhage assigned by an intelligent white lady, living in the house, was a severe fit of crying, said to have been due to hunger on the part of the child, and inattention on the part of the mother. I found the flannel binder around the body of the child saturated with blood, and other portions of its clothing containing large blood-stains, altogether showing that the child had lost a fatal quantity of the vitalizing fluid. The child was almost exsanguinated, and uttered a very feeble cry. On examination of the source of the hemorrhage I found it located in the centre of the umbilical protuberance, from which dark, venous-colored blood freely oozed. The blood did not coagulate.

As the hemorrhage was still very free, and serious results were to be apprehended from its further continuance, I passed two steel pins through the base of the umbilical protuberance, at right angles to each other, and applied a ligature, wound several times around, beneath the pins. This checked the bleeding most successfully, notwithstanding which the child died ten hours after, apparently from exhaustion.

Grandidier has collected four cases of spontaneous umbilical hemorrhage occurring on the fourteenth day, and twelve cases occurring at later periods, up to the fifty-sixth day after birth.* The recoveries in this accident of infancy were seventeen per cent. in 220 cases.†

As regards the cause of the hemorrhage in the case that I have given, the washing away of the clot in the umbilical vein, by the straining exertions of the child during the fit of crying, is, to my mind, the only solution of the question. A case occurring from the same cause is recorded amongst Grandidier's cases.

The method which I used for checking the hemorrhage, commonly called the Dubois method, is recommended by Grandidier only as a *dernier ressort*. He prefers using a graduated compress applied to the umbilicus over a pledget of lint saturated in the liq. ferri sesquichlor., and bound tightly around the abdomen.

BILIARY FISTULA,

OPENING AT THE UMBILICUS, AND THROUGH WHICH PASSED ELEVEN BILIARY CALCULI.—RECOVERY.

By CHARLES E. SLOCUM, M.D.,

DEFIANCE, OHIO.

Mrs. M., æt. 33, had always enjoyed good health save some transitory fevers of malarious origin.

Had been suffering occasional severe pains in the hepatic and gastric regions for a month or two, when there commenced a pouting and soreness in the umbilical region, followed, April 25th, 1871, by an opening at the umbilicus, through which was discharged a watery, bilious fluid, sometimes staining the cloths a little yellow and green. There was but little pus.

From three to four inches upwards and outwards, to the right from the umbilicus, there was felt a hard mass which was diagnosticated as the enlarged gall-bladder, and with which the fistula was supposed to communicate, but whether by way of the *round ligament* of the liver, made pervious, or of an independent ulceration tract, could not be determined.

She was at this time three months advanced in her third pregnancy. The pains and flow continued with some regularity until August 25th, when they increased in frequency and severity, and two gall-stones were passed from the umbilical opening.

Calculi continued to pass at intervals of one or two weeks, so that at the time of her confinement, October 27th, seven had been collected. She complained much that the fluid discharges from the fistulous tract were "as cold as ice."

She had taken but little medicine, and that of a character to relieve pain and keep the secretions in order, with a little quinine to allay occasional tendency to fever. Had been around the house and feeling quite well between her pains.

She did well during her labor, but was much annoyed for two or three weeks after with pains, and finally fever, periodical in character, which was soon relieved again by quinine. From the time of her confinement to December 20th, four calculi were passed, the eleventh and last one passing at this date.

There was no jaundice at any time. The fistula closed soon after the passage of the eleventh calculus, since which time she has been quite free from pain and tenderness in and about the regions affected.

Her general health has since been quite good, and an examination of the hepatic and umbilical regions at the time of this writing, April 24th, 1873, shows no indications of her former trouble.

The calculi ranged from five-eighths to one and one-eighth inch in circumference, were brownish yellow in color, and generally contained six facets.

Disinfectant.—Dr. Muscroft, of Cincinnati, Ohio (*The Clinic*, Feb. 15, 1873), recommends a disinfecting lotion composed of 1½ ounce of the bicarbonate of soda and 1 ounce of powdered alum, dissolved in water. He uses this mixture for every kind of sloughing sores.

* Die Freiwilligen Nabelblutungen der Neugeborenen, Cassel, 1871.
† Grandidier, loc. cit.

Reports of Hospitals.

CHARITY HOSPITAL, N. Y.

NOTES OF PRACTICE AND PECULIARITIES IN TREATMENT.

BURNS.

A lotion recommended for burns consists of—

℞ Sulphate zinc.....grs. xv.
Co. spts. lavender.....℥ i.
Aqua.....one pint.
M.

Buck's burn mixture is also employed, the formula for which has been previously given.

ERYSIPELAS.

The only successful method of treatment which has been employed for arresting the spread of the disease is the formation of a boundary-line by means of a blister. For this purpose, the vesicatingcollodion is ordinarily used. If erysipelas attacks a limb, encircle it with a blister about one-half or three-quarters of an inch wide, at a free point above the part affected.

A very common, and most excellent, application for the erysipelas, is an ointment composed of—

℞. Sulphate of Iron.....℥ i.
Sapo or unguentum ceræ.....℥ i.
M.

In this way the iron can be used, and the stains avoided, which are so annoying when employed in solution.

SIMPLE CERATE.

A modification of this dressing is used which renders it much more agreeable, and much easier of manipulation in cold weather.

It consists in the addition of oil of almonds, in the proportion of ℥ i. to ℥ i. This makes one of those little variations in surgical dressings which may add to the comfort of the patient and the convenience of the surgeon.

PERSISTENT VOMITING.

There was a case of persistent vomiting in connection with Bright's Disease. The patient was a female and this was the second attack, she had suffered. A number of months previous in her first attack, the vomiting was sufficiently persistent to reject all remedial agents employed for its relief, and it was supposed that the patient must then and there die.

She was placed, however, upon treatment by the use of raw beef, or so nearly raw that it could hardly be said to be an infringement upon the proper use of te ms to call it raw, and she began immediately to improve. Her recovery was complete so far as the vomiting was concerned. Her second attack had come on only a few days previous to my visit, and she was placed upon the beef treatment at once. The results were equally satisfactory with the first, and the patient was now able to take iced milk with her beef, and was feeling very comfortable.

The beef, raw and seasoned with a little salt and pepper, or cooked in the slightest degree over coals and seasoned in the same way, is taken in quantities averaging about one ounce every three hours. It was cut in small pieces, set by the bedside, and the patient administered it "piecemeal."

SPRAINS.

This class of injuries is placed at once in a Plaster-of-paris splint.

Absolute rest and external support are the essentials in treatment.

SUBACUTE PLEURISY.

Tonics are regarded as an essential element in the treatment of this affection (quinine and iron chiefly), and their administration is made the leading feature.

The utility of tapping is looked upon as questionable; at all events, it is not to be resorted to early.

Diuretics are administered only for the purpose of maintaining the quantity of urine at its normal standard. When a diuretic is required, infusion digitalis is the one commonly employed. Some of the potassa salts arecombined with it if not sufficiently active when administered alone.

ULCERS.

A dressing which is said to serve a most admirable purpose for any ulcerated surface which may need a soothing and slightly stimulating application, is the ceratum resinæ et bals. Peruvian. It is usually employed in the proportion of one part of balsam to four of ceratum.

HOW TO REMOVE ADHESIVE PLASTER.

Every surgeon, doubtless, is familiar with the appearance of a part which has been enveloped in adhesive plaster, after the straps have been removed. The appearance is not one in very good keeping with a cleanly and neat surgical dressing. The portion of the plaster which is left adhering to the skin may be quickly and completely removed by the use of oil of turpentine and sweet oil. Use a little more than half turpentine. This compound, carefully rubbed over the parts with a bit of cloth or sponge, and then washed off with warm soap-suds, will leave the surface as clean as nature ever intended.

NECROSIS.

A man had his thigh amputated, on account of necrosis of long standing, near to the knee joint and involving the joint somewhat. He had had some hemorrhages from the opening, and amputation was performed as the most reliable means for saving the man's life. When the amputated portion was examined, there was found a thin sharp spicula of bone just ready to pierce the popliteal artery, which, doubtless, had given rise to the previous hemorrhages. The practical considerations in connection with this case are these:—

Trifling hemorrhages from the granulations which line the cavity of the involucrum are not infrequent, but hemorrhages in old cases of necrosis are quite apt to be dependent upon a more serious cause. They may be produced by the contact of a piece of bone with a large vessel, perhaps, and usually it is with a vessel of some size.

The vessels with which the pieces of bones come in contact and produce hemorrhages are arteries, for the reason that external irritation upon veins fills their cavities with thrombi. This filling of the vessels with thrombi may occur to a slight extent in small arteries, but with large arteries it is not the case. If a severe hemorrhage has occurred from an old necrosis, it is very sure that an artery has been opened by a spicula of bone coming in contact with it, and the only sound practice is to go immediately down upon the artery, and tie it above and below the wound, or amputate the limb at once.

Hesitation in these cases may sacrifice the life of the patient. The examination of the limb in this case shows the reasonableness of this view.

CHANCROIDS.

A goodly number heal rapidly, when dressed with pure iodoform. Occasionally a rebellious one needs to be once thoroughly cauterized, and after this will heal kindly by the use of the iodoform.

SYPHILIS.

Mercury, usually in the form of pechloride or bi-chloride, is employed in the secondary stage, but in the tertiary forms, iodide of potassium is relied upon exclusively. It is given in large doses. The patient receives 15 grs. three times a day for two or three days, and then 20 grs. three times a day, and so on, increasing the doses until he is taking 30 grs. three times a day, which is called the normal quantity. Upon this iodide of potassium diet, the patients are steadily kept, unless they get too fat, when it may be necessary to discontinue it for a while.

STRANGULATED HERNIA.

A man, over 70 year of age, was brought to the hospital having a strangulated hernia, which had been *tampered* with for some time previous to his admission. The man was feeble and there were evidences of peritonitis present. The aspirator was used in this case and about one ounce of serum drawn off, but the relief afforded was not sufficient to permit the reduction of the gut. The ordinary operation was then performed. Post-mortem revealed extensive peritonitis. Delays in the reduction of strangulated hernia are dangerous.

When will tampering surgeons learn to avoid these delays?

Progress of Medical Science.

HYDRATE OF CHLORAL IN INCONTINENCE OF URINE.—Dr. Girolamo Leonardi has found chloral a most valuable remedy in nocturnal incontinence of urine. The dose for children is from five to ten grains taken in water before going to bed. For adults the dose is proportionately larger. The treatment has been successful in all of his recorded cases. The remedy must be repeated for several successive nights.—*Lo Sperimentale*, April, 1873.

ACTION OF COLD WATER ON THE SPLEEN.—The importance which many authors, and Fleury especially, have ascribed to cold water as a remedial agent in intermittent fever and various other affections of the spleen has induced Prof. Mosler, of Greifswalde, to test its efficacy, and he has arrived at the following conclusions:—

1. The direct contact of cold water with the normal spleen causes it to contract appreciably, and the degree of contraction varies according to the temperature of the water and the length of time for which it is employed.

2. Cold water also acts similarly on the normal spleen, if applied over the abdominal walls, but it is less effectual. In such cases the cold douche is to be preferred to cold compresses or bits of ice, but in all of them it accomplishes less than quinine.

3. In all forms of enlarged spleens, the result of disease, whether acute or chronic, the action of cold water causes contraction of the organ.

4. The paroxysms of intermittent fever can be arrested by Fleury's method of using the cold douche, but it has no advantage over quinine, either in new or old cases.

5. The cold douche does not accomplish a permanent cure of this fever. It does not always prevent recurrence, and leaves the spleen enlarged.

6. The spleen of typhoid fever is diminished in size by the same remedy.

7. In all forms of enlargement of the spleen, whether acute or chronic, the application of cold water to the spleen, either in the form of cold baths, ice-bags, or cold douches, with the internal use of quinine at the same time, is to be preferred to either of these methods alone.

8. As a substitute for quinine in chronic cases, quinoidine is recommended as being very much cheaper.—*Archiv. f. path. anat.*, lvii., 1.

TINCTURE OF IODINE IN ELEPHANTIASIS ARABUM.—At the last session of the Academy of Medicine in Paris, for the year 1872, Olivade reported several cases of elephantiasis Arabum which he had treated successfully with large doses of the tincture of iodine. He employed it internally and externally. Commencing at first with a few drops, he gradually increased the dose to a drachm, and the success was proportioned to the amount given. The tincture was applied externally on long strips of linen. In every case, marked improvement showed itself by a diminution in the size of the affected part, and by the altered character of the skin. After the lapse of three months, during which moderate compression was kept up, the disease had nearly entirely disappeared.—*Mem.*, 3.1873.

INVESTIGATIONS ON EPITHELIAL CANCER.——Dr. William A. Carmalt, of this city, in a recent article published in Virchow's Archives makes some valuable contributions to the history of epithelial cancer. He mentions that among fifty or sixty such growths occurring on the cheeks and lips in patients coming under his own observation, only two were in women and none were in full-bearded men, corroborating the statement of Fuehrer that it is most common in persons who shave. In opposition to Koester's theory that the cancer-cell may be developed from the endothelium of the lymphatic vessels, he found by employing the silver method that no proliferation in these cells was apparent, and, in fact, that when carefully separated from the cancer-cells filling these vessels, the endothelium had undergone no change whatever. On the other hand, he believed that he traced direct connection between cancer-cells and the altered epithelium of the hair-follicles.

Experiments as to the capacity of independent motion in the living cells of new growths resulted as follows: by removing fresh cells from the living body and immediately mounting them in the serum which escaped, and maintaining their normal temperature on a heated table, he observed amœboid motion in individual instances. The changes these bodies underwent in form were similar to those observed in the white blood-corpuscles mingled with them. The activity of the latter, however, was more marked. The investigations were carried out at Prof. Waldeyer's laboratory in Breslau.—*Archiv. f. path. anat.*, lv.

TRAUMATIC FLEXIONS OF THE UTERUS.—Alex. J. Stone, M.D., St. Paul, Minn. (*Northwest Medical and Surgical Journal*), for the past two years has had his attention called occasionally to flexions dependent upon a traumatic cause, and publishes a case. He believes that, while to the submucous stratum the uterus owes

much of its firmness, the muscular parenchyma aids in giving this support to a considerable extent.

Small-pox Keratitis.—Dr. A. D. Williams, St. Louis, Mo. (*Med. Archives*), combines atropine with carbolic acid in the treatment of small-pox keratitis—the carbolic acid aiding greatly the effect of the atropine. The proportions are as follows: R. atropine sulph., gr. iv.; acid. carbolic, gr. v.; aquæ destilat., ℥ j. Mix. To be dropped in the eyes three to five times a day, according to severity of the keratitis; two or three times at night, if there is much pain. In addition to this treatment, in cases of deep ulceration of the cornea, where the healing process is slow, a very strong solution of the acid (15 to 30 grs. to the ounce) may be applied directly to the ulcer once a day. First cleanse the ulcer well, and dip the end of a small probe into the solution and touch the small drop that sticks to it directly to the bottom of the ulcer. This will spread over the ulcerated surface and turn it instantly white. It smarts sharply for a moment. Care should always be taken to confine this strong solution to the abraded surface of the cornea.

Boracic Acid as a Preservative for Milk.—According to A. Hirschberg (*New Remedies*), the addition of 15 grains of boracic acid to two pounds (equalling a quart) of milk will keep it sweet in hot weather for five days. The usefulness of the milk is said not to be impaired, but the cream rises more slowly than normal.

Experiments with the Cundurango.—Dr. Edmund Andrews, of Chicago (*Med. Examiner*, 1873), and others, have been experimenting with fluid extract of cundurango on 23 cases of common ulcers, cancer, soft chancres and the eruptions and ulcerations of tertiary syphilis, and come to the following conclusions: Cundurango has no equal in the materia medica in its power to increase the growth of granulations, and hasten the cicatrization of ulcers. It acts favorably in soft chancre (after cautery), and on the ulcers and eruptions of tertiary syphilis. His experiments on hard chancre are not yet extensive enough to be decisive, but, as far as they go, they tend to the idea that cundurango has no influence on hard chancre, nor on the earlier eruptions of secondary syphilis. The remedy has not produced, under his observation, any effect on the growth and progress of cancerous tumors. It however often diminishes the pain and the discharges, and if the tumor has been excised, hastens the healing of the wound. It generally increases the appetite, diminishes constipation, and acts on many patients as a very powerful general tonic. Full particulars of the cases, which were under the care of Dr. Byford, Powell and himself, are given in the appended tables.

Exophthalmic Goitre.—J. Forsyth Meigs, M.D., Phys. to Penn. Hosp'l (*Phila. Med. Times*), in his clinical lecture "On a Case of Exophthalmic Goitre," says that, in his later cases, he has used digitalis with benefit. Digitaline granules, gr. 1–60, three times a day, sometimes answer perfectly.

The External Application of Veratrum-Viride.—Dr. Anson Ford, of Battle City, Montana (*Jour. Gynæcological Soc.*), writes, that in the absence of all the remedies usually exhibited, he applied to *a supposed cancer of the left breast* Norwood's tincture of veratrum viride, and was astonished at its immediate and almost magical effect. The induration of the gland and the excruciating pain disappeared under this treatment. A cloth was kept over the gland, saturated with the solution, and over all oil silk, to prevent evaporation. Was it cancer?

The Pulvis Glycyrrhizæ Compositus.—David Page, M.B., Edin. (*Can. Med. Record*), recommends the compound liquorice powder, a preparation of the Prussian Pharmacopœia, especially in simple constipation resulting from atony of the bowel. It is composed of the following constituents, so prepared as to form when incorporated an almost impalpable powder: Senna leaves, ℥ vj.; liquorice root, ℥ vj.; fennel seeds, ℥ iij.; sulphur, ℥ iij.; refined sugar, ℥ xvij. The usual dose is a small teaspoonful at bedtime, in water, forming an agreeable draught.

Carbolic Acid of no Value in Intermittent Fever.—In order to test the assertions of Freulich, that the internal use of carbolic acid is a good substitute in cases of intermittent fever, V. Havard, M.D., A. A. Surg. U. S. A., Camp Grant, A. T. (*Western Lancet*), has tested its value in 19 cases. He comes to the conclusion that this acid possesses but little, if any, of the antiperiodic properties attributed to it. It was given mostly in quotidian cases, as this variety is the common one in Arizona, and in doses from two to three grains, three times a day.

Acute Diseases of the Heart.—W. F. McNutt, M.D., San Francisco, Cal. (*Western Lancet*), mentions two cases of acute disease of the heart, accompanied and masked by functional derangement of the brain, which came under his care. These resembled the sixteen reported by George Burrows, M.D., of London, and the three cases published by Prof. A. Flint. The character of the delirium in most of the recorded cases, was characterized by taciturnity and maniacal excitement, "under the influence of delusions, involving the idea of having committed some crime." In his cases, one patient would insist upon it that he had been stealing from his employer and should be sent to jail; the other, that he had committed a great mistake in business. He says that it must not be forgotten that grave cerebral symptoms are essential elements of disease of the heart.

Nephrotomy.—W. W. Dawson, M.D., of Cincinnati, Ohio (*N. Y. Med. Jour.*), reports a case of extraction of a calculus from the kidney of a married woman, aged 50 years, who had borne nine children, and had always been a healthy and robust woman until eight years ago, when she had an attack of hæmaturia. The patient died on the fifth day. The calculus was quite light, weighing only 20¾ grains, and measuring seven-eighths of an inch in length by half an inch in breadth at its widest part, being uniform in shape. It was ammoniac magnesian phosphate, and situated on the internal wall at a point corresponding to the hilus of the kidney, and was embedded in partly disorganized fibrin. The kidney-tissue which he incised was about one-half inch in thickness, and bled but little.

Febris Diphtheroides.—G. Harrison Gray, A. A. Surg. U. S. Navy, attached to the U. S. Naval Hospital, Yokohama, Japan (*Am. Jour. Med. Sciences*), proposes the name febris diphtheroides for a disease which has attracted his attention, and which differs sufficiently from any other. So far as he is aware it has never been described, and is peculiar to Chinese rivers. He first observed it up the Yang-Tse-Kiang River, afterwards at Shanghai, still later at Ningpo, both these places being on fresh-water rivers, and finally the last traces of it disappeared when the ship again commenced cruising in salt water. Though

diphtheria is by no means an unknown or uncommon disease in the northern part of China, especially about Pekin, and though intermittent fever abounds in all parts of the country, this disease which he has called diphtheroid fever, and which presents some of the features of both those mentioned, seems peculiar to fresh-water rivers, and was unknown to physicians who had resided for a long time where he saw it. From this he fancies some of the elements necessary to the production of the disease were carried there in the ship, for while in Corea many of the crew had suffered with a sort of sub-acute pharyngitis, and the trip up the Yang-Tse-Kiang followed immediately after the return from Corea.

The Early Symptoms and Treatment of Insanity.—In a paper read before the Bristol North District Medical Society, Dr. W. W. Godding, Phys. to Lunatic Asylum, Taunton, Mass. (*Bost. Med. & Surg. Jour.*), gives the following symptoms and management of insanity: In nine cases out of ten there will be marks of disorder about the clothing or person in some way, for, as a rule, the insane show untidiness of dress; the insane are often uneasy, in a constant motion, getting up, walking about the room, busy with nothing. Later in the disease, they will sit for hours in the same position; sometimes this is so from the commencement, not usually. Depression, as shown in the whole manner as well as in the countenance, is seen in the early stage of insanity, in a majority of cases. Dr. Saukey goes so far as to claim that no attack of insanity occurs primarily without an incubating stage of depression. He doubts the truth of this, but it is a very common condition. Hallucinations of hearing are not very uncommon in insanity and must be regarded as an unfavorable symptom. Hallucinations of sight are, in his experience, much rarer in insanity than in delirium. Want of sleep occurs in a great majority of the cases of insanity, and it is surprising how long they will sometimes survive apparently without sleep, and yet in the end recover. The return of sleep is often the commencement of convalescence. The digestion is impaired in the early stages. Sometimes the moral sentiment alone seems to be at fault. A not very uncommon form of this is seen in young persons recovering from typhoid fever. Paresis seems the very inflorescence of insanity. In regard to the early treatment, in the active forms of insanity, the two important points are to keep up the strength and to secure sleep. The first is best done by nourishment, and in many cases he thinks an early resort to the feeding tube is the humane and the only justifiable course to pursue. There is no doubt but it might be used to advantage much oftener than it is, outside of hospitals. No year passes that he does not see lives saved by its use. A full meal is often a better sleep-compeller than an opiate. Milk, egg and brandy, with a little nutmeg and sugar, is very palatable and anodyne in its action. As a hypnotic, chloral hydrate is the favorite reliance, in doses of 20–30 grains at bedtime; it will bear to be repeated, but not indefinitely. But in mania all drugs are uncertain in their effect. He holds that insane persons are not to be taken indiscriminately to a hospital simply because they are insane.

Ampho-Diplopia Cured by Operation.—Dr. D. S. Reynolds, Louisville, Ky. (*Am. Practitioner*, March, 1873), records a case of this affection, in which he lays claim to an entirely original method of manufacturing an inferior oblique muscle out of the internal rectus, as well as an efficient method of relieving double vision resulting from persistent spasm of the superior oblique.

Crystallized Digitaline.—The directions given by M. Brugnet for preparing pure crystallized digitaline are as follows: The drug is exhausted with fifty per cent. alcohol, the alcohol recovered by distillation, and the residue concentrated to a weight equal to that of the digitalis originally used. This concentrated extract holds in solution the digitaline, but, on dilution with three times its weight of water, it deposits nearly the whole of this principle in an impure state, but free from the digitaline and other soluble principles, which interfere with the crystallization of the digitaline. The deposit is dried and extracted with twice its weight of boiling proof-spirit, which dissolves the digitaline. As the solution cools it deposits crystals, which continue to form till the liquor is exhausted. The digitaline is separated from the digitine by extraction with chloroform, and, after treatment with animal charcoal, is recrystallized from boiling alcohol.

Crystals thus procured are fine, white, shining needles arranged in stellate clusters. They are intensely bitter, give a wonderfully intense emerald-green coloration with hydrochloric acid, and produce the peculiar physiological effects of digitalis in extremely minute doses—$\frac{1}{250}$ of a grain.—*Med. Press and Circular.*

Epistaxis a Means of Vicarious Menstruation.—A case of this character is mentioned by Dr. Otto Obermeier (*Brit. and For. Med. Chir. Review*, July, 1872), in a servant-girl, aged 24. At the age of 15, the first catamenia appeared, which was profuse. Epistaxis came on the following month, and appeared regularly for several years, until pregnancy in 1870, when it terminated, but again came on six weeks after parturition, and continued regularly for some months, when conception took place. Three days was the usual run of the epistaxis, which was attended by muscæ volitantes, malaise, feeling of giddiness, etc.

Large Child.—At a recent meeting of the Obstetrical Society of Boston, Dr. Minot said he had lately attended a lady whose child, when dressed, weighed but a trifle less than fifteen pounds!

ARTICLES IN OUR EXCHANGES.

SURGERY.

A case of fracture of the internal table of the os frontis alone, the external table remaining unbroken; death; post-mortem. Triplett, W. H. *Boston Med. and Surgical Jour.*, April 17.

Contributions to the history of the surgery of Tennessee. Bailey, F. K. *Nash. Jour. Med. and Surgery.*

Report on Tennessee surgery. Briggs, W. T. *Ibid.*

Two cases of vesico-vaginal fistula, with operations for the relief of the same. Miller, J. G. *Kansas City Med. Jour.*, April.

The operation for hare-lip, with two cases and photograph. Brigham, Chas. B. *Western Lancet*, March.

Reduction of a dislocation five months after injury. Toland. *Ibid.*

On the surgery of the nares, larynx, and trachea. Cohen, J. Solis. *Phila. Med. Times*, April 19, 26, and May 3.

Elongation of the uvula. Lewis, F. B. A. *Boston Med. and Surgical Jour.*, April 17.

Tracheotomy in a case of membranous croup; recovery. Emerson, Nathaniel B. *N. Y. Med. Jour.*, May.

Rupture of œsophagus. Bailey, Jas. S. *Ibid.*

Cases of lithotomy. Cabot. *Boston Med. and Surg. Jour.*, May 1st.

A case of necrosis of the cranial bones in connection

with disease of the mastoid cells. ASHHURST, SAMUEL. *Phil. Med. Times*, April 26.

Ligation of the subclavian artery for axillary aneurism. ARMSBY, JAMES H. *Phil. Med. Times*, May 3.

A mechanical appliance to restore the features after the excision of an osseous tumor of the superior maxilla. KEITH, H. H. *Missouri Dental Jour.*, April.

Phagedenic ulceration of the rectum. WHITEHEAD, WM. R. *Southern Med. Record*, April.

How to secure union by first intention. GARRISON, J. B. *Med. and Surg. Reporter*, May 3.

Facial paralysis treated by a new method. DETMOLD, WM. *N. Y. Med. Jour.*, May.

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, June 2, 1873.

THE AMERICAN MEDICAL ASSOCIATION.

THE recent meeting of the American Medical Association was a remarkable one, insomuch as there was an absence of the disgraceful quarrels which have characterized its proceedings for the past few years. This, so far as it goes, gives a promise for a better future, and shows that the entire session can be carried through without the occurrence of anything that should mar its usefulness or reflect upon its dignity. Although we are willing to admit that this is a source of congratulation to the friends of the Association, and is a circumstance which is in every way encouraging, we are nevertheless convinced that something more than at present exists is needed to warrant the continuance of such meetings. It is true the members present seemed to be actuated by a common purpose to make this meeting a memorable one, and, in so far as their wishes were concerned, they succeeded. But this was not a very difficult task, under the circumstances. Fortunately, none of those test questions which have heretofore called forth such angry discussions in open session came up. There was evident a disposition to avoid them from the beginning, and the sequel proves this course to have been the wise one. The Association could not in reality dare to repeat some of its previous performances before the world. The profession were so painfully impressed with the necessity of some reform, that unless some change were inaugurated at once the Association would lose all its former prestige, and it would forever part with its claims as a representative body. Enough was done at St. Louis, however, to prove that there is still an abiding interest felt in the welfare of the Association to warrant its continuance, and to assure all its friends that it is capable of redeeming its lost reputation. On former occasions we have discussed the propriety of reorganization as the best means of insuring this end; and despite the apparent capability of the Association to manage its own affairs in the old way, we are still convinced that our opinion is the correct one. There is a crying necessity for such an alteration in the constitution and by-laws as shall effectually prevent the discussion in public of all questions which have an interest for the profession alone; as shall settle them in some other and more effectual way than by ending in a family quarrel, which is made the most of by the daily press. Our readers are already sufficiently familiar with our plan of change. We do not claim it to be perfect—we do not wish to place it above all others. Our desire has been and still is to do the best that can be done to bring about the best result. We care not which plan may be adopted so long as this end is attained.

The formation of a large committee, to whom all the important questions in ethics shall be referred, is, in our opinion, the most practical one—one which will not involve so much of alteration in the present plan of organization as many of the others which have been proposed by our contemporaries. It is vain to hope that every meeting can be so managed as to prevent the presentation of these questions. Such is an impossibility, in view of the recognized office of the Association, as a tribunal before which all doubtful points must be judged. The profession, as a body, are interested in their solution, and their proper solution has an important influence upon the standard of American medicine. The only thing to be done is to settle them in a becoming and satisfactory manner. So long as the present organization exists, we are convinced that this never can be done without endangering still more the reputation of the Association for respectability, and without incurring the chances of a repetition of disgraceful performances. We must prevent the annual parade of twaddle from such of the members as never give the subject any other thought than that which is engendered by the mere hearing of a report. There are always to be found, in every assemblage, learned and unlearned, persons who have more impudence than brains, and whose sole ambition seems to be to make a speech upon the slightest pretext. These are the very men who have done so much injury to the Association, and whose opinions have been quoted as representative of the general professional feeling. This parade of nonsense could be checked at once by having all such questions referred to a sufficiently large, influential, and respectable committee with power, and by having any necessary discussion upon the report conducted in private. Dr. N. S. Davis, true to the reputation which he has enjoyed of having the best interests of the Association at heart, and willing to do anything calculated to enlarge its scope of usefulness,

presented in substance the amendment proposed by us. We were sorry to see it laid upon the table, but are not discouraged at this result. Time will be given during the coming year for a thorough discussion of the merits of the proposed change, and in all probability at the next meeting the members may be ready and willing to act upon it. If any improvement be suggested, we shall be glad to see it incorporated.

As an evidence of desire to improve the usefulness of the Association in other directions, we have the adoption of the suggestions of the committee of which Dr. E. L. Howard, of Maryland, is chairman, in reference to reorganization of the sections, the vesting of discretionary power in the Committee of Publication in regard to papers which shall appear in the Transactions, and the provision, at the suggestion of another committee, for complete phonographic reports of the various proceedings of these sections. These changes cannot fail to give an interest in the scientific proceedings of the Association, and stimulate the best men to attend the meetings.

There are many other subjects which were brought up before the Association to which we cannot refer to in detail. One of the most important of these was the matter referring to army promotions, presented by Dr. Woodward. The resolutions adopted concerning the same will receive the hearty indorsement of the entire profession.

Dr. Peck, of Iowa, seconded, in a very appropriate manner, our suggestion in regard to the action which the Association should take concerning the Medical and Surgical History of the Rebellion. The Association, by promptly and unanimously adopting these resolutions, did credit to itself.

The sections were reasonably well attended; but the papers, with few exceptions, did not come up to the standard of last year.

Dr. Pollock's Report on Medical Education was an exceedingly sensible one, and the same may be said of the Report of the Committee on the Nomenclature of Diseases.

But we must content ourselves for the present by simply referring our readers to the report in full in another column.

MEDICAL EXPERTS.

With certain medical gentlemen there seems to be a strong desire to be considered medical experts. Especially is this disposition shown in cases of questionable insanity before our courts. We have always considered that to be an expert required a thorough and practical acquaintance with the subject, but the apparent necessity of the times seems to have rendered this unnecessary. The pleas of moral insanity, emotional insanity, and the like, are now considered to be such forlorn hopes that the lawyers seem to be willing to take the opinion of any one who may volunteer it. The consequence is, we are getting a new instalment of experts not known or recognized as such by the profession, but nevertheless of value as figure-heads. At a recent trial in New York we saw a number of respectable medical practitioners lending their names to the court and stultifying themselves by the expression of opinions for which they had no possible foundation. The study of insanity has been recognized as a specialty for the last quarter of a century; and it is fair to suppose that there are thousands of questions that can be put by an attorney which are unanswerable, save on the basis of a very extensive practical experience in the treatment of the disease. A physician who has not such an experience places himself in a false position by claiming to be qualified to give an opinion. There would be no disgrace for any practitioner to acknowledge incompetency in this respect, if called upon. We hope that in future any such who may be urged for an opinion may have the moral courage to acknowledge ignorance before it is made so evident in a crowded court-room, and through the columns of the daily papers. It is also obviously unfair to the real experts on insanity—the gentlemen who have the best opportunities for studying the disease—gentlemen who are connected with our insane asylums—to have the crude opinions, formed by a hasty glance at some authority, foisted upon the public as representing the advanced views of the present day. It is just such cases as these that give the legal profession the whip-hand of the medical profession, and give rise to the complaint, on our part, that the former never lose an opportunity to make fools of us. We believe that every one has his place; and if some of the medical tortoises trust to the legal eagles to teach them to fly, they must learn, sooner or later, that the higher they are taken into the air the more disastrous will be their fall when left to their own resources.

PRELIMINARY EXAMINATION FOR STUDENTS.

The Medical Society of the State of New York has recently made it obligatory on the part of every County Society to examine all gentlemen intending to study medicine, and give them a certificate of their fitness. How far this provision is carried out we are not able to say. We know of two counties in the State who make it a regular practice, one of which is the Ulster County Medical Society. We were present at the last monthly meeting of this body, and witnessed such an examination, which was remarkably thorough, and conducted by the committee with a determination to fulfil the full letter of the law. If other similar societies are not in the habit of complying with the regulations, we take the opportunity of holding this one up as an example of what can be done in this direction. We should like to hear from other quarters.

HOMŒOPATHY IN THE UNIVERSITY OF MICHIGAN.

The bill establishing two chairs of homœopathy in the University of Michigan has become a law. So

far as the present Faculty is concerned, the question is simply, shall they abandon their posts (which will result in placing the whole school in the hands of the homœopaths, and so ruin one of the best institutions in the country), or shall they maintain their ground and continue to teach truth right in the face of error, and without reference to the punctilious etiquette, miscalled ethics, which would make them turn tail to a mere shadow and desert their proper work and duty? We say to them, as Sumner said to Stanton, "Stick!"

HEALTH DEPARTMENT OF NEW YORK.

THE new Health Commissioners are Chas. F. Chandler, President; Dr. S. Oakley Vanderpoel, Health Officer of the Port; Dr. Stephen Smith, and Henry Smith, President of the Police Board. The President, Prof. Chandler, is to all intents and purposes a medical gentleman, and is in every way qualified for his position, as is also the Health Officer. Dr. Stephen Smith is a reappointment. Mr. Henry Smith is a politician pure and simple, but will no doubt do everything he can to earn a reputation for efficiency. On the whole, then, the Board may be considered a remarkably well-selected one, the majority possessing the ability for their work and the necessary amount of backbone to enforce their regulations without fear and without favor.

MEDICAL DECLARATION CONCERNING ALCOHOL.

MANY of the prominent members of the medical profession of this city have made a declaration to the effect that alcohol is a powerful drug, and when prescribed medicinally should be "with conscientious caution and a sense of grave responsibility." It is also declared that "the use of alcohol as a beverage is productive of a large amount of physical disease,—that it entails diseased appetites upon offspring, and that it is the cause of a large percentage of the crime and pauperism of our cities and country." We heartily indorse the circular and hope that some good may come of it. The only end that in our opinion it can serve is to lead many of those practitioners who prescribe stimulants so recklessly to reflection upon the responsibilities which they assume. We have always held that alcohol should be prescribed with as much caution as opium, and should never be left to the discretion of the patient.

The third clause of the circular "welcoming any judicious and effective legislation—State and National—which should seek to confine the traffic in alcohol to the legitimate purposes of medical and other sciences, art, and mechanism," is visionary in the extreme, but is well enough to give some faint encouragement to such as believe that appetites can be controlled by legal enactment.

SANITARY SUPERVISION OF SCHOOLS.

WE are surprised to learn that the Board of Education has abolished the office of Sanitary Superintendent. We were beginning to congratulate the public on the promise of good things to come in the shape of improvement in the sanitary condition of our schools. Dr. O'Sullivan, who held the office, was just getting the machinery of reform in order, and in the short space of six months did more to initiate important changes than all the visiting committees together had done in five years. The suggestions which he made were of the greatest importance to the health of the children, but were seemingly unheeded. Now we are told that the office is a useless one. If this be so, then the Board of Education must be ready to affirm that the schools are in good sanitary condition. Which is which?

THE ENDOWMENT FUND OF THE COLLEGE OF PHYSICIANS AND SURGEONS, N. Y.

BY the time this number of THE RECORD reaches our New York City subscribers, those among them who are graduates of the College of Physicians and Surgeons will have received the Appeal of the Councillors of the Alumni Association, urging them to contribute money toward the establishment of a Scientific Department in connection with the College. We have watched this movement of the alumni with anxious interest, and are thoroughly satisfied with the sound practical shape it has finally assumed. The profession at large—no matter from what school its individual members may have taken their degrees—will be deeply interested in the success of this undertaking, as it aims, not so much to benefit the College proper, as to open the way for a higher standard of medical education and to foster scientific investigation. The day is not far distant, we believe, when New York will vie with Vienna and Berlin in the inducements it can offer medical students both for the practical and the scientific branches of their professional studies.

We are authorized to state that the Councillors are particularly anxious that *every* alumnus of the college should contribute to this fund. There are probably very many graduates, who will not feel able to contribute more than five dollars as their share. We earnestly hope that these men will not withhold their subscription, in the belief that the sum is too small to be of any real assistance in raising the comparatively large sum of $100,000. Such a mode of reasoning will very materially increase the labors of the Councillors, who have determined that this sum *must* be raised. In our next issue we shall take occasion to discuss at length the general principle of endowment of our medical institutions.

DR. JAMES L. BROWN.—The concert recently given by the Vocal Society for the benefit of the family of Dr. James L. Brown netted over $5,000. It is pleasing to add that the Society gave their services, and that Mr. Steinway tendered the use of his Hall for the occasion.

Reports of Societies.

AMERICAN MEDICAL ASSOCIATION.

TWENTY-FOURTH ANNUAL SESSION AT ST. LOUIS, MO.

May 6, 7, 8, 1873.

DR. THOMAS M. LOGAN, of Sacramento, Cal., President.

THE twenty-fourth annual meeting of the American Medical Association was held at Masonic Hall, St. Louis, commencing May 6, 1873.

The meeting was called to order at 11 A.M. by Dr. D. W. Yandell, of Louisville, after which prayer was offered by Rev. Dr. Nicolls. Dr. John S. Moore, of St. Louis, then delivered the address of welcome, after which the President elect, Dr. Thomas M. Logan, being presented to the Association, delivered an address.

THE PRESIDENT'S ADDRESS.

After referring to the interest felt in the Association all over the country, and particularly by such members who journeyed across the Rocky Mountains to attend the meeting in San Francisco, he alluded to the necessity of exacting of the medical colleges a higher standard of preliminary education, and a more thorough and exacting course of instruction afterwards. In this latter connection he paid Harvard University a deserved compliment for taking a stand in the right direction and of establishing a system of instruction thorough, practical, and in every respect up to the requirements of the present age of progress and reform. He also urged the necessity of cultivating the science of public hygiene, and through it the education of the people upon subjects concerning which they now desire to be informed. This was one of the ways whereby medicine could gain and maintain for itself a legitimate influence upon the community whose welfare they were bound to consider. The only way to command respect for the profession was to educate the people to the point of appreciating its benefits. The more they were informed of its utility and power, the better would they be able to withstand the inroads of quackery and incompetency. The people were ready to be taught, and the profession had but to seize the opportunity, to control opinion as effectually in matters of hygiene as does the pulpit matters connected with morality and religion. To this end the public lecture-room and the press could be used with advantage to all parties concerned. In this connection he remarked:—

"When I recommend, as one of the means of widening the usefulness of the Association, the judicious instruction of the community in the knowledge of the science of life, I do not wish it to be understood that we are to do more than spread abroad such sound ideas of enlightened hygiene as will enable the people to cooperate with us in correcting all those formidable obliquities—physical, mental and moral—which are insidiously polluting the stream of humanity, so that the race may move onward and upward, in purity of type, to a higher and nobler manhood. In the furtherance of this end, I believe our Association will exert a powerful influence. Such publications as your President now proposes cannot be misconstrued—they cannot be tortured into violations of the code. If by any means they can, then let us amend our platform—add a new clause to our ethics—so that we do not prove recreant to that duty which even our very title of doctors, *teachers*, implies. No wisdom, however mature, could at once have originated a system competent to meet all the exigencies time and progress may give rise to. As our Association advances towards the consummation of its purposes, it must be expected that new necessities will arise, and experience in the working of the plans laid out at first will demonstrate the nature of the changes for adaptation to existing circumstances."

In conclusion, he recommended that the alternate meetings of the Association be held at Washington, as heretofore.

The speaker received the thanks of the Association, and the address was, according to custom, referred to the Committee on Publication.

REORGANIZATION OF SECTIONS, ETC.

DR. E. LLOYD HOWARD, of Maryland, presented the Report of Special Committee on Reorganization of Sections and Publication of Transactions, and moved that it be made the special order of business for 10 A.M., Wednesday.

The St. Louis Mutual Life Insurance Company extended an invitation to the members of the convention to visit their new building, on the corner of Sixth and Locust streets.

A letter was read from Postmaster C. I. Filley, of St. Louis, tendering the members of the Association special postal facilities in the shape of an extra mail-box, etc.

A paper on the education of the last census, by Dr. E. Seguin, of N. Y., was offered, and referred to its appropriate section.

The several committees were then called upon for reports, the majority of whom reported progress, and were continued. The report of Dr. Pollok, "on Medical Education," was made the special order for Thursday, 11 A.M.

After the transaction of business of minor importance, the Association adjourned until 9.30 A.M., Wednesday.

PROMENADE CONCERT IN EVENING.

The members enjoyed a Promenade Concert during the evening, at Mercantile Library Hall. The music consisted of a double orchestra of thirty pieces, under the leadership of Prof. A. Waldauer. The stage was beautifully decorated with flowers, and all the other arrangements were dictated by a refined taste, and reflected credit upon the Committee of Arrangements. A suitable refreshment was also provided, which was tasteful in every sense of the word.

SECOND DAY, *May* 7, 1873.

DR. T. M. LOGAN, President, in the Chair.

The meeting was called to order by the President, at 9.30 A.M.

An invitation was read by W. B. Atkinson, Secretary, from Mr. Dyer, to visit the Mercantile Library.

COMMITTEE ON NOMINATIONS.

The following Committee on Nominations was next announced:—

Arkansas, A. L. Brysacker; Alabama, G. Moses; Connecticut, W. A. Wainwright; District of Columbia, F. Howard; Georgia, J. P. Logan; Illinois, H. A. Johnson; Indiana, W. H. Meyers; Iowa, A. M. Carpenter; Kansas, D. W. Stormont; Kentucky, R. H. Gale; Maine, A. Gardlow; Maryland, S. P. Smith; Massachusetts, L. F. Warner; Delaware, H. F. Askew; Michigan, W. Brodie; Minnesota, A. B. Stuart; Missouri, J. B. Johnson; Mississippi, J. W. M. Shattuck; New Hampshire, E. F. McQuesten; New Jersey, S.

Lilley; New York, H. W. Dean; North Carolina, R. J. Hicks; Ohio, A. Dunlap; Pennsylvania, W. J. Asdale; Rhode Island, L. Morton; Tennessee, W. T. Briggs; Texas, D. R. Wallace; Virginia, T. D. Cunningham; West Virginia, G. Baird; Wisconsin, E. P. Russell; United States Army, B. A. Clement; United States Navy, E. Eversfield.

CONCERNING SECTIONS AND REORGANIZATION.

DR. E. L. HOWARD read his report on Reorganization of Sections, &c., recommending among other things the presentation of papers before said Sections in abstract, and the propriety of referring all lengthy documents to a sub-committee.

Resolved, That section 9, article 1, of the by-laws be amended to read as follows:—"The reading and consideration of the reports of the standing committee of publication and prize essays, and of chairman of sections."

Resolved, That article 1 of the by-laws be amended as follows:—"In first paragraph strike out order of sections," as it now stands, and insert instead, "new arrangement of sections." After second paragraph insert:—"The section on State medicine and public hygiene shall be composed of one member from each State, representing, as far as practicable, the State Boards of Health, the officers of this section to be also designated by the Committee on Nominations." "The chairman of the several sections shall prepare and read in the general sessions of the Association papers on the advance and discoveries of the past year, in the branches of science included in their respective sections; the reading of such papers not to occupy longer than forty minutes for each." After third paragraph insert:—"No paper shall be read before either of the sections, the reading of which occupies more than twenty minutes. Such papers shall be referred by the section to sub-committees specially appointed for their examination. The sub-committees shall be allowed thirty days for such examinations, at the end of which time they shall forward the papers to the Committee of Publication, with such recommendation as they may deem proper. The authors of such papers, however, may read abstracts before the session within the allotted twenty minutes. No member shall address the session more than once upon the same subject, nor speak longer than fifteen minutes without unanimous consent."

Resolved, That article 3 of the by-laws be amended as follows: Strike out all that relates to the Committee on Medical Education, on Medical Literature, and on Climatology and Epidemic Diseases; and insert in first paragraph, after Committee on Prize Essays, "Committee on Ethics" In place of fourth paragraph insert:—"The Committee on Ethics shall consist of nine members, to serve for three years, and until their successors are appointed, any vacancies occurring to be filled for the unexpired term by the Committee on Nominations. Their duties shall be to examine and adjudicate all questions of a personal character, including complaints and protests, and all questions on credentials that may be referred to them by the Association. The decision of the committee shall be final, until reversed by the Association, but no appeal from their decisions shall be brought before the Association until the following year."

Resolved, That article 4 of the by-laws be amended by adding—"The Committee of Publication shall have full discretionary powers to omit from the public transactions, in part or in whole, any paper that may be referred to it by the Association, or either of the societies, unless specially instructed to the contrary by vote of the Association."

Resolved, That a new section (11) be added to the by-laws, as follows:—"No new business, resolutions by members, etc., shall be introduced at the general sessions of the Association, except on the first and fourth days of meeting."

DR. BRONSON, of Massachusetts, submitted a minority report, objecting to that portion of the previous report specifying the duties of the Committee on Ethics. He proposed to limit their duties to all questions of a personal character, including complaints, protests and all questions as to credentials. The committee to act forthwith and to report their proceedings to the Association, to be disposed of by a majority vote.

PROPOSITIONS BY DR. S. D. GROSS.

A letter was read from Professor Gross, urging the adoption of an amendment proposed by him at the previous meeting of the Association to the following effect:—

That, instead of a report on medical education, on medical literature, and climatology and epidemic diseases, there shall be annually delivered before the Association, at its general meetings, an address in medicine, an address in surgery, an address in midwifery, or the diseases of children, the lecturers to be appointed this year by the President; afterwards by the Committee on Nominations.

DR. N. S. DAVIS moved that the report of the committee be received, and all except that referring to the Committee on Ethics be adopted.

DR. PORTER spoke against the amendment.

The previous question was called and Dr. Davis's motion prevailed.

SUGGESTIONS FOR IMPROVING THE ASSOCIATION.

DR. DAVIS next offered the following amendment to the by-laws:—

A Council, consisting of twenty-one members, shall be appointed by the Nominating Committee, whose duty it shall be to take cognizance of and decide all questions of an ethical or judicial character that may arise in connection with the Association. Of the twenty-one members of the Council first appointed the seven first named in the list shall hold office one year, and the second seven named shall hold office two years. With these exceptions, the term of office of members of the Council shall be three years, seven being appointed by the Nominating Committee annually.

The said Council shall organize by choosing a President and Secretary, and shall keep a permanent record of its proceedings. The decisions of said Council on all matters referred to it by the Association shall be final, and shall be reported to the Association at the earliest practical moment.

All questions of a personal character, including complaints and protests, and all questions on credentials, shall be referred at once, after the report of the Committee of Arrangements, or other presentation, to the Judicial Council, and without discussion.

DR. DAVIS also proposed, as an addition to the Code of Ethics, section twelve, to add, "and that three members be annually appointed to deliver addresses on medicine, obstetrics and diseases of women and children, no address to occupy more than forty minutes in its delivery."

On motion of DR. E. L. HOWARD, these documents were laid on the table and the original report of the committee adopted.

REORGANIZATION OF ARMY MEDICAL CORPS.

The hour having arrived for the reception and consideration of a report upon a reorganization of the Army Medical Corps:

DR. J. J. WOODWARD, Assistant Surgeon U. S. A., read the following:—

"*To the President of the American Medical Association:* SIR—It is proposed to present herewith a brief statement, showing that the medical staff of the United States army has not been placed on an equal

footing with the other staff corps of the army as regards rank, that they have not had the same consideration shown them in this respect as has been accorded to the navy, and that the record of services of this meritorious body of officers entitles them to the same advantages that have been granted to others.

"When the rebellion broke out the medical staff of the army, with a total of 115 officers, had but one of higher rank than that of a major, while in the quartermaster's department, with thirty-seven officers, five were above that rank; in the commissary department, with twelve officers, two were above that rank; in the adjutant-general's department, with fourteen officers, two were above that rank; in the engineers, with 129 officers, there were seven; in the pay department, out of a total of twenty-eight, there were three, and in the ordnance department two out of thirty-six.

"The act of Congress, July 28, 1866, defined the 'Peace establishment of the United States,' and reorganizing, as it did, with the view of permanence, all the various departments of the army, it might have been supposed that equal justice in the matter of rank would have been meted out to each separate branch of the staff. That this was not the case so far as the medical department is concerned is shown by the following: —

"By its provisions the total number of medical officers was fixed at 217, seven of whom were above the rank of Major, or 3.22 per cent. The Quartermaster's Department was to consist of 76 officers, seventeen of whom were above that rank, or over 22 per cent.; the Subsistence Department of 29 officers, five being above that rank, or 17 per cent.; the Adjutant-General's Department of 20 officers, seven being above that rank, or 35 per cent.; the Engineers of 109 officers, of whom nineteen were above that rank, or over 17 per cent.; the Ordnance of 64 officers, with eight above that rank, or 12.50 per cent.; and the Pay Department of 65 officers, five being above that rank, or 7¾ per cent. It is thus seen that the Medical Department was given a smaller proportion of officers of rank than any other staff department, being less than one-half of that granted to Paymasters, one-quarter of that in the Ordnance, nearly one-sixth of that in the Engineers and Subsistence Departments, less than one-seventh of that in the Quartermaster's, and about one-twelfth of that given to Adjutants General.

"The medical officer under the present law is accorded the rank of Captain after three years' service; he is promoted to Major by seniority, such promotion not ordinarily occurring in less than fifteen years' service, and that is the end of his prospects of advancement, unless he may be so fortunate as to secure a Medical Purveyorship, which can necessarily be within the reach of but very few, those positions being but five in number, and vacancies in consequence occurring but very seldom. Not only is this a great injustice to those surgeons on the active list, but it operates still more injuriously toward those old and meritorious officers who, having given their best years to the country, become disabled by age or infirmity, and are desirous of availing themselves of the privileges of the retired list. The Adjutant-General, Quartermaster, or Engineer of thirty years' service can almost certainly retire with the rank of Colonel, certainly that of Lieutenant-Colonel, while the veteran surgeon is laid aside with the rank of Major, and an income hardly sufficient to support his station as a gentleman, or to sustain his family.

"The Medical Department is not willing to be accorded a second place in comparison with any other arm of the service. It points with pride to its roll of honor during the last war, to the thirty-eight of its members who were killed in action or died of wounds, to the twelve who were killed by accident in the performance of duty, to the four whose lives wasted away in rebel prisons, to the seventy-three who were wounded in battle, and to the 271 who died from the diseases and exposure of camp life (an array of figures greater than can be presented by any other staff corps), as a proof that they were always to be found where duty called.

"Without any disposition to make an invidious comparison between the Medical Department and other staff corps, it is believed that at least as high a grade of intellect, as finished an education, as eminent scientific attainments are required to make an accomplished medical officer, as obtains in any other branch of the service. In the case of the vast majority of other staff officers, this education is obtained at the expense of the government, which not only furnishes the future Adjutant-General or Engineer with all the advantages which a scientific school can afford, but actually pays him a handsome salary for four years before he is sufficiently accomplished to render any service therefor. Not so the medical officer. He must obtain his education at his own expense, usually spending years in college, in medical schools and hospitals, before he can hope to be sufficiently qualified to pass the ordeal of an examining board.

"The government cannot expect to obtain the best class of men in any branch of its service unless it offers them equal inducements to those found in civil life. So long as medical men of ability and good scientific acquirements have before them those high prizes which are found in private practice, just so long will they refuse to continue in the army, when no prospect is held out to them of ever rising above a certain grade, or of obtaining beyond a certain amount of income.

"The inducements to engaging in private practice are the prospect of increased income and reputation with advancing years. In the army, these are represented by *rank*, not only because increased rank carries with it an increase of emolument, but also because to the army officer rank is well and properly understood to enhance the dignity of the person holding it, as well as the respect in which he is held by his compeers and subordinates.

"The rank of medical officers should therefore be no less than that of the other staff corps; they require an equal education and equal abilities, they perform equally arduous duty, they sustain as great responsibilities, they are exposed to like dangers, and in the distribution of the rewards of the military career they should be entitled to an equal share. That they are not at present on this footing of equality has been clearly shown in the foregoing comparisons.

"The principles here urged have already been recognized in the recent legislation for the Medical Department of the navy, by which fifteen medical officers were given the relative rank of Captain, and fifteen that of Commander, corresponding to the rank in the army of Colonel and Lieutenant-Colonel respectively. It is held that no good reason exists why similar promotion should be withheld from the army surgeons, when its necessity has been acknowledged by law for their brethren in the navy.

"The British War Office has likewise recognized the importance of increased rank for its medical officers, in the new 'Army Medical Warrant,' and has acknowledged the force of the positions taken in this

paper, by giving such rank in recognition of long and faithful service.

"A further injustice has been done, not only to the medical staff, but to the profession at large, by the legislation which at present forbids any promotions or new appointments in the Medical Department. To the former, because, from the rapid depletion which ordinary casualties make in its ranks, it throws increased labor upon those who remain, and necessitates the employment of physicians under contract, who, having but a temporary tenure of office, cannot be expected to be actuated by that single regard for the service which is a *sine qui non* to the faithful performance of duty. To the profession at large, for it prevents many who are desirous of entering the military service from doing so, and thus perhaps compels them to abandon a design to the accomplishment of which their education may have been especially directed. There are now sixty-one vacancies in the medical staff, fifty-three of them being in the grade of assistant surgeon. Should promotion be restored, it would then take at least two years to fill the vacancies now existing.

"The result of the continuance of the present state of affairs will be, that many of the candidates for examination, and no doubt the most deserving, will, impatient at delay, seek other channels of usefulness.

"In view of all these facts, it is believed that an appeal made by so representative a body as the American Medical Association, numbering, as it does, delegates living in every Congressional district in the United States, would not be without its effect, and it is earnestly suggested to its members that they will take such action as may seem to them most proper, as will result in placing their professional brethren in the army on an equal footing with those of the navy, as well as with the officers of the other staff corps of the army, and also to throw open once more the door for the admission of the young physicians of the country to the ranks of the army medical staff." (Signed)

and others.

DR. WOODWARD remarked:—Mr. President, I had nothing to do with drawing up this letter, but I indorse it fully, as does also the Surgeon-General. It is understood that by the provisions of the army regulations we of the army are debarred from making such an appeal, but we can aid the suggestion verbally by appealing to you, gentlemen of the Association. Any army officer, except a Surgeon, can be retired in old age with a competent pay and the rank of Colonel, while a medical man can only have the rank of Major after twenty years of service, and may ask for a Lieutenant-Colonelcy at thirty years. A Lieutenant-Colonelcy is all we ask. I was an Assistant Surgeon twelve years ago, and hold the same rank yet. I have filled my contract with the Government, but it has not fully complied with its obligations. We have come up to this Convention for help. We only ask what was done for our brethren of the Naval Medical Corps, and nothing more.

DR. KELLER, of Louisville, then presented the following resolutions, which were unanimously adopted:—

Resolved, That in the opinion of this Association the rank of the medical officers of the army ought to be fully equal to that of the officers of any other staff corps, or of the medical corps of the navy. That we learn with regret that this is not the case, and that we regard with grave disapproval the odious discrimination thus made against a meritorious body of officers.

Resolved, That we look upon the law which prohibits promotion and appointments in the medical corps of the army as unwise and unjust, and that, in our opinion, it ought forthwith to be repealed

Resolved, That a committee of five be appointed by the President, to memorialize Congress on this subject, and that each member of this Association pledges himself to use all his influence with the member of Congress from his own district in behalf of the object of these resolutions.

The President appointed as the committee, Dr. Keller, of Kentucky; Askew, of Delaware; W. S. Davis, Chicago, Ill.; John Murphy, Cincinnati, O.; J. M. Toner, Washington, D. C.

DR. YANDELL said he would favor the matter if the words "rebel prisons" in the letter were changed to read "Confederate prisons." The change was accordingly made.

DELEGATES TO THE BRITISH MEDICAL ASSOCIATION.

The Secretary read the following appointments made by the President to represent the American Medical Association to the British Medical Association:—Drs. F. G. Smith, C. Wister, J. S. Cohen, of Philadelphia; Dr. E. Warren, of Baltimore; Dr. C. L. Ives, of New Haven; Dr. Edward Montgomery, of St. Louis, and Drs. F. Barker, E. Seguin, J. C. Hutchinson, of New York.

REPORT OF NOMINATING COMMITTEE.

DR. JOHNSON, of St. Louis, Chairman of the Nominating Committee, made the following partial report:—

Your committee suggest the following gentlemen for the various offices named:—

President—Dr. J. M. Toner, District of Columbia.
First Vice-President—Dr. W. Y. Gadbury, of Miss.
Second Vice-President—Dr. J. M. Keller, of Kentucky.
Third Vice-President—Dr. W. C. Husted, of Missouri.
Fourth Vice-President—Dr. L. D. Warner, of Massachusetts.
Treasurer—Dr. Casper Wistar, of Philadelphia.
Librarian—Dr. Wm. Lee.
Committee on Libraries—Dr. Johnson Elliott.
Secretary—Dr. Theodore A. McGraw.
Committee on Arrangements—Dr. Brodie, Chairman; James A. Brown, Morse Stewart, J. F. Noyes, E. W. Jenks, Henry F. Lister, D. O. Farrard, Eugene Smith; all of Detroit.
Committee on Prize Essays—Drs. J. K. Johnson, A. Sager, H. Hitchcock, of Detroit; E. Andrews, Ill.; E. S. Gaillard, Ky.
Committee on Publications—Drs. F. G. Smith, W. B. Atkinson, D. Morrey Chester, of Penn.; Wm. Lee, District of Columbia; Casper Wistar, Penn.; F.H. Askew, Delaware; Alfred Stilli, Penn.

Detroit was named for the next annual meeting of the Association. The report was adopted.

MEDICAL EDUCATION.

Dr. Carson, of Ohio, presented a report on Medical Education of which the following is an abstract:—

It is within the knowledge of the whole profession that there is much dissatisfaction regarding the important question of medical education, and particularly with reference to the results of the agitation of it in this Association. There is reason to think that at the basis of this dissatisfaction there lies a misconception of the influences affecting medical education, and of the functions of this body pertaining thereto. A proper consideration of these influences will show that some of them impose limitations upon medical education which are beyond the power of the profession or of this body to control in any great degree, and that from others are evolved the spirit and method of new teaching, which are much within the personal efforts of all physicians to direct and control, and, therefore, that the administrative agencies, under which we include every form of teaching, whether private or public, in office or college, are not responsible for failures of performance in the first direction, while in the latter they and all of us are largely so. These influences are classified as, first, those originating in the external relations of medicine, such as government, general education and culture, physical and economical necessities. Secondly, those originating in the internal relations of medicine, such as are involved in the study and practice of the accessory and direct sciences and arts of medicine. Third, there are certain conditions, derivative from these in the operation of the administrative agencies, which exert important effects upon the results of medical education. Political influence, he said, often determined the form which the instructing body should take. The first institutions for medical education were organized in a spirit of freedom, and were entirely outside of State control. He would hesitate to sanction the proposition to place medical education in the hands of the government. General education often determined the character of the professional education. There was no other feasible plan to elevate the latter than to wait the slow development of that high standard of general education requisite. The report suggested how instructions could aid materially in advancing the standard of medical education by properly grading their instruction, and concluded as follows:—We conceive, then, that by recognizing the fact that we have two classes of influences reacting on medical education, which we have called the external and the internal, of all of which it may be said that they are the products of growth under certain definite and inherent impulses, with power of adaptation modification, etc.—of the first of which it may be said that they are very stable elements, of the second it may be said that they are moving with the swift velocity of modern science. We conceive, then, that the power and function of our medical administrative agencies and of this Association may be more clearly defined. It would diminish the responsibility placed upon the schools in all matters pertaining to the external relation of medicine, while it would hold them to increased responsibility in all matters belonging to the subjective work of their position. It would show that this Association can only exert great influence by increasing its efficiency as a tribunal before which these subjects may be brought for the exercise of that most potent influence, discussion; and not for that impotent purpose of expecting to increase legislative functions towards the teaching bodies. If amendatory action be desired, for this and other good purposes, then we herewith advocate it.

The report was referred to the Committee on Publication.

REPORT ON MEDICAL LITERATURE.

Dr. Yandell, Jr., read the report on Medical Literature. The medical journals throughout the country were said to be improving and were beginning to be in consequence self-sustaining.

NO PRIZES GIVEN.

The Prize Committee could not find any one worthy of a prize.

The Treasurer's report showed a balance of $496.74 in the treasury.

The reports of the Librarian and Committee on Publication were likewise read and appropriately referred.

Dr. Toner read a statistical paper on Medical Colleges and Medical Societies.

THE LATE DR. SAMUEL HENRY DICKSON.

The Secretary read an obituary of Dr. Samuel Henry Dickson, of Philadelphia, which was ordered to be entered on the minutes.

THE MEDICAL AND SURGICAL HISTORY OF THE REBELLION.

Dr. Peck, of Iowa, introduced the following resolutions, which were unanimously adopted:—

In view of the fact that the reports of the Surgeon-General of the United States Army, as exhibited in volumes one and two of the first part of the Medical and Surgical History of the War of the Rebellion, have received a too limited circulation by reason of an insufficient issue of the same by Congress, therefore

Resolved, That the President and Secretary of this Association be directed to petition Congress at the next session in behalf of the profession, asking that the edition recently issued be reproduced in sufficient number to permit of general distribution to the members of the profession throughout the country.

Resolved, That the thanks of this Association are due and are hereby tendered Congress for aiding thus far in developing and presenting to the profession reports of the Surgeon-General, as herein specified.

Resolved, That the thanks of this Association are hereby tendered the officers of the United States Army who have by sacrifice and labor been instrumental in placing before the profession the valuable information contained in volumes one and two of the first part of the Medical and Surgical History of the War of the Rebellion.

AMENDMENT TO THE CONSTITUTION.

Dr. N. S. Davis submitted the following amendment to the Constitution or plan of organization, to be acted upon at the next annual session:—

It is proposed to strike out the second paragraph of article 2, commencing with "The delegates," and ending with "of pairs," and insert the following:—

"The delegates shall receive their appointment from permanently organized State medical societies, and such county and district medical societies as are recognized by representation in their respective State societies, and from the medical department of the army and navy of the United States of America."

Also, strike out all of the fourth paragraph of same article 2, beginning with "each local society" and ending with "one delegate," and insert the following:—

"Each State, county, and district medical society, entitled to representation, shall have the privilege of sending to the Association one delegate for every ten of its regular resident members, and one for each additional fraction of more than half that number. The medical staffs of the army and navy shall be entitled to four delegates each."

THE CENTENNIAL CELEBRATION.

Dr. Frederick Horner, Jr., U. S. N., offered a reso-

lution that the American Medical Association appoint a committee of one member from each of the original thirteen States of the Union, to report to the Centennial Celebration on the medical, surgical and biographical literature of the period of 1776, as a tribute to Joseph Warren, Benjamin Rush, Arthur Lee, General Hugh Mercer, and other noble and patriotic physicians who aided to secure American independence. Adopted.

PHONOGRAPHERS FOR THE SECTIONS.

DR. DAVIS introduced a resolution to provide for suitable preparations for full and careful reports of the proceedings of the various sections at the next annual meeting, which was adopted, and a committee of five appointed for that purpose.

A resolution was introduced and passed to authorize the surgical section to employ a short-hand reporter.

A paper by DR. GUION, of the United States Navy, upon the subject of medical education, was referred to the section on practical medicine.

The Association then adjourned to 9:30 Thursday.

THE MORRISON RECEPTION, WEDNESDAY EVENING.

In accordance with a previous reception, the members were entertained at the residence of Col. and Mrs. J. L. D. Morrison. Waldauer's band was in attendance, and the guests, numbering three hundred, passed a very entertaining evening. An elegant repast was furnished.

THIRD DAY, *May* 8.

DR. THOMAS M. LOGAN, President, in the Chair.

DELEGATES TO BRITISH MEDICAL ASSOCIATION.

The Secretary announced that Dr. O'Hagar, of North Carolina, and Dr. Eades had been added to the list of foreign delegates already published.

NOMENCLATURE OF DISEASES.

The Chairman of the Committee on Nomenclature of Diseases made the following report:—

In accordance with the resolutions appended to the minority report of the committee, adopted by the Association at its last meeting, one thousand extra copies of the proposed nomenclature were printed in pamphlet form, and distributed to the profession and to the various medical journals, both at home and abroad; and that such criticisms and suggestions as would represent their opinions as to its merits and fitness were invited from those receiving it. To this invitation not a single response has been made by medical journals, and but from two practitioners, the latter being such additions as in the judgment of these gentlemen would render the work more complete, but which in the judgment of the majority describe symptoms which none but a specialist could recognize. From this statement of the results of a year's consideration of the proposed nomenclature, the conclusion may be drawn that the profession are satisfied with the work. Your committee are not willing to entertain the only other conclusion, that men of culture and practical men are indifferent upon a subject of such importance; they therefore again present the resolution appended to the majority report and ask for its adoption:—

Resolved, That the report of the Committee on the Nomenclature of Diseases be referred to a special committee of five members, to be appointed by the President, who shall examine it and report upon its final disposition, at the present meeting of the Association.

Resolved, That on the favorable report of such committee it shall be referred back to the Committee on the Nomenclature of Diseases, for the preparation of an index to be published with it, in the forthcoming volume of the transactions.

The Secretary moved the adoption of the report.

DR. WOODWARD opposed the adoption of the motion and gave in detail his reasons therefor. He then offered the following as a substitute:—

Resolved, That in the opinion of this convention it is inexpedient to adopt the nomenclature and classification presented by the majority of the Committee on Nomenclature at the meeting in Philadelphia.

Resolved, That a committee of three be appointed by the President, whose duty it shall be to communicate the foregoing resolution to the proper Committee of the Royal College of Physicians of London, and to negotiate for the representation of the American Medical Association in the first decennial revision of their nomenclature.

Adopted.

PERMANENT MEMBERS.

The Committee on Nominations, to whom was referred the subject of permanent membership, reported through their Chairman, Dr. J. B. Johnson, the following names for admission to the Association:—

Edwin Stewart, Mendon, Michigan; G. L. Polk, Acola, Illinois; T. W. Hollowbush, Warsaw, Illinois; John Shore, St. Louis; Wm. Van Zant, St. Louis; Daniel Lichty, Rochelle, Illinois; B. F. Edwards, Kirkwood, Missouri; L. A. Grimes, Lewis County, Missouri; C. W. Crary, St. Louis; L. T. Newman, St. Louis; George F. Center, Olney, Illinois; Drs. R. J. Mitchell, Lewis Wilcox, R. J. Allmond, W. C. Day, R. T. Cowan, and Edwin Blakesley, all of Illinois; John E. Faber, St. Louis; Dr. Randall, Illinois; Dr. Vinnedge, Lafayette, Indiana; Charles N. F. Ludwig, St. Louis.

DR. TONER, D. C., presented the following resolution in regard to an

INTERNATIONAL MEDICAL CONGRESS:—

Resolved, That, in the opinion of this Association, it would be an excellent opportunity, at the American Centennial in 1876, for an International Medical Congress to consider, and, if practicable, to adopt, a uniform classification and nomenclature of diseases, to be used by the profession throughout the world.

AMERICAN AND FOREIGN WINTER CURES.

A letter was read from DR. H. R. STORER, residing at present in Mentone, near the Mediterranean, asking the Association to examine into the comparative merits of foreign and American winter cures. The communication was referred.

CASE OF DR. PALUEL DE MARMON, OF KING'S BRIDGE, N. Y.

DR. DAVIS, Chairman of the Committee on Ethics, reported in the case of Dr. De Marmon, against whose admission last year at Philadelphia a protest was made, as follows:—

"Dr. De Marmon held credentials as a regular delegate from the Westchester County Medical Society in New York, to the meeting of the Association in 1872. But at that meeting a protest against his admission was made, on the ground that he was on trial for unprofessional conduct in his local society. The subject was referred to this committee at so late a period of the meeting that it could not be acted upon. From the evidence recently presented to our committee, it appears that the trial of Dr. De Marmon is still unfinished in the Westchester County Medical Society; that said Society has formally withdrawn his credentials as a delegate to this convention, and con

sequently no present action in the matter is required by this Association."

Adopted.

THE PATHOLOGICAL SOCIETY OF BERKS CO., PENN.

The following report of the same committee was likewise adopted:—

"At the meeting of the American Medical Association in Philadelphia, May, 1872, objections were made to the admission of delegates from the Pathological Society of Berks county, Pa., on the ground of unprofessional conduct on the part of many of the members of that Society. Time not permitting a full hearing of the case during that meeting of the Association, a report on it was postponed until this meeting of the Association. In the mean time, the accused parties were duly notified of the charges, and requested to make answer thereto. After a full investigation of the case, your Committee on Ethics, appointed in 1872, declare a sufficient number of the charges sustained to justify the recommendation that the said Pathological Society of Berks county be not allowed a representation in this Association."

SALARY OF THE PERMANENT SECRETARY.

The committee appointed to consider the propriety of giving the Permanent Secretary a salary, made a report adverse to specifying any fixed sum for that officer.

DR. KELLER, of Louisville, after considerable discussion, offered the following, which was adopted:—

Resolved, That the sum of $500 be appropriated as an honorarium for the services of the Permanent Secretary during the present year, provided such an amount remains in the treasury after paying necessary expenses.

NATIONAL SANITARY BUREAU.

DR. BELL, of New York, offered the following:—

Resolved, That, in the judgment of this Association, the establishment of a National Sanitary Bureau, with relations to the General Government similar to those of the Bureaus of Agriculture and Education, is highly desirable as a means of promoting sanitary science and the protection of the public health.

Resolved, That this Association request of the United States Educational Bureau to so extend its scope of inquiry as to include vital diseases and mortuary statistics, in relation to local meteorological and geological influences, and to disseminate the information so collected throughout the country.

The resolutions were adopted and referred to the Committee on Public Hygiene.

DR. M. A. PALLEN offered the following:—

Resolved, That Congress be memorialized to create a Sanitary Bureau, and that it be under the control of the Surgeon-General of the U. S. Army.

Lost.

DR. BELL said the resolution of Dr. Pallen would not meet the ends desired. It would have to go through the circumlocution offices at Washington, and it would be years before anything could be accomplished. He was opposed to the substitute.

The original resolutions were then adopted.

The hour of 11 having arrived, the special order of business set for that time,

REPORT ON MEDICAL EDUCATION,

was taken up. DR. POLLOCK, chairman of the committee, presented the following report:—

"The committee appointed by the President at the last meeting of the Association, to take into consideration the propriety of adopting the suggestions of the Committee on Medical Education, are fully impressed with the importance of the subject, and acknowledge the value of the suggestions offered. But we believe it wholly impracticable to carry into operation any law which does not meet the hearty approval of the diverse interests connected with the teaching and practice of medicine. And while we have no doubt that this Association has grown to be a power in the profession, felt and recognized by all, yet to make this power effective its decisions should be calm and deliberate; therefore, your committee, after due deliberation, have concluded to recommend the adoption only of the conclusion of the report of the Committee on Medical Education, which is as follows:—That a Congress composed of two members from each State and Territory, and one from each recognized medical college, all to be members of this Association, be appointed (or nominated by the Nominating Committee) at this present session; that said committee or Congress shall meet three days previous to our next annual meeting, and that said committee or Congress shall perfect a plan for some uniform system of medical teaching, which, when adopted by the Association, shall be the only recognized method of medical teaching in the United States."

Considerable discussion followed. First, the report was adopted, by a close vote; then a motion was made to reconsider the vote, which was done. Then a motion was made to lay it on the table; then that motion was withdrawn.

DR. KELLER, who had seconded the motion to lay it on the table, contended that the gentleman who made the motion had no right to withdraw it without consent of the second. He did not consent, but insisted on the motion to lay the report on the table.

DR. YANDELL was opposed to the clause of the report which referred to the election of one from each medical college by the Nominating Committee. With that exception he would be in favor of the adoption of the report.

DR. BRODIE, of Massachusetts, thought there were other objections to the report, and that it was a usurpation of authority.

The motion was put by the Chair, and the report was finally laid on the table.

The paper on yellow fever, presented by Dr. Mitchell, of Brenham, Texas, was called up and referred to the section on the theory and practice of medicine.

DR. J. P. GARRISH, of New York, extended an invitation to the members of the Association to visit New York, and when there not to miss the chance of seeing the Medical Library of New York.

ELECTING OFFICERS.

DR. E. L. HOWARD, of Maryland, presented the following resolution, which was, by the rules, laid over until the next meeting:—

Resolved, That article 4 of the Constitution be amended as follows:—Strike out second clause of first paragraph and insert: "They shall be nominated by the Judicial Council, and shall be elected by vote on a general ticket."

APPOINTMENTS FOR 1874.

The Committee on Nominations presented the following report of officers of sections and committees for 1874:—

Practice of Medicine, Materia Medica and Physiology—Chairman, N. S. Davis, Illinois; Secretary, Dr. Frothingham, Michigan.

Obstetrics and Diseases of Women and Children—Chairman, Theophile Parvin, Indiana; Secretary, Montrose A. Pallen, Mo.

Surgery and Anatomy—Chairman, S. D. Gross, Pennsylvania; Secretary, Alonzo Garcelon, Maine.

Medical Jurisprudence, Chemistry and Psychology—Chairman, A. N. Tully, South Carolina; Secretary, E. L. Howard, Maryland.

State Medical Publications and Hygiene—Chairman, A. N. Bell, New York; Secretary, A. B. Stuart, Minnesota.

State Medicine and Public Hygiene—F. A. Ross, Alabama; D. A. Linthicum, Arkansas; T. M. Logan, California; R. G. Buckingham, Colorado; B. H. Catlin, Connecticut; L. P. Bush, Delaware; F. Howard, District Columbia; W. F. Westmoreland, Georgia; H. A. Johnson, Illinois; W. H. Myers, Indiana; J. J. N. Angier, Iowa; D. W. Stormont, Kansas; Louis Rogers, Kentucky; S. Fitch, Maine; James Stewart, Maryland; H. I. Bowditch, Massachusetts; R. C. Kedzie, Michigan; A. B. Stuart, Minnesota; J. W. M. Shattuck, Mississippi; John S. Hodgen, Missouri; John F. Parsons, New Hampshire; E. M. Hunt, New Jersey; A. N. Bell, New York; W. A. B. Norcon, North Carolina; Wm. Clendennin, Ohio; A. M. Pollack, Pennsylvania; E. M. Lenox, Rhode Island; R. A. Kinlock, South Carolina; W. T. Briggs, Tennessee; D. R. Wallace, Texas; J. L. Cabell, Virginia; J. Bromfield, West Virginia; H. B. Stung, Wisconsin; A. T. Woodward, Vermont; S. M. Bernis, Louisiana.

Resolved, That the Secretary of the Association be authorized to fill up all vacancies in the committee from the States and Territories.

Also, that Dr. A. N. Bell be President, and Dr. A. B. Stuart as Secretary.

Judicial Committee, Three Years—Drs. Brodie, Michigan; Davis, Illinois; Howard, Maryland; Baldwin, Alabama; Dean, New York; Logan, Georgia.

Two Years—Joynes, Va.; Todd, Ind.; Askew, Del.; Morgan, D. C.; Lillie, N. J.; Benham, Pa.; Dunlap, O.

One Year—Bartlett, Wis.; Powell, Ill.; Gale, Ky.; Moses, Mo.; Hughes, Ia.; Bemis, La.; Bronson, Mass.

Necrology—Chairman, A. Sager, Mich.; and the committee to remain as last year, excepting Alonzo Garcelon, of Maine, in place of Dr. D. McRuer, deceased; D. W. McCabe, Kan.; J. W. H. Baker, Iowa; J. D. Wheeler, N. H.; Dr. Millegan, Minn.; W. M. Chambers, Ill.; G. Sutton, Ind.; A. J. Sands, Ga.; B. A. Naugh, Miss.; Geo. Mitchell, O.; J. J. Woodward, U. S. A.; N. M. Dodson, Wis.; J. B. Yandell, Ky.; Dr. Stuart, Winona, Minn.

Dr. H. R. Storer was appointed chairman of the special committee to report on American as compared with foreign winter cures.

The report was adopted.

Dr. McPheeters called up the amendment proposed to the proposed amendment to the Constitution, in regard to the

UNITED STATES MARINE HOSPITAL SERVICE.

The proposed amendment was:—"That the United States Marine Hospital Service be placed in the same relative position in the American Medical Association as the Medical Departments of the United States Army and Navy," is proposed to be amended by the addition of the following provisions:—"Provided that the said Marine Hospital Service does not differ in permanence of character from the United States Army and Navy services, and that it is not subject, in official appointments and regulations, to partisan or political influence and authority; and provided, further, that nothing herein contained, and nothing contained in the plan of organization, shall be so construed as to authorize the recognition, as constituent, of any institution or body, or the admission or retention as delegate or member, of any practitioner of medicine, unless such institution, body or practitioner be of a character, description or class which was fully and clearly recognized and approved as of unquestionable standing, and so entitled to representation or admission, at the date of the adoption of said plan of organization; or unless such institution, body or practitioner shall thereinafter be so recognized and approved by legal amendment of said plan of organization."

On motion of Dr. N. S. Davis, the matter was laid on the table till next year.

Dr. Pallen announced that carriages would be in waiting at the hall from 1.30 to 2 o'clock to-day, to convey the members to Tower Grove Park and Shaw's Garden.

REPORT OF COMMITTEE ON THE CINCHONA TREE.

The committee appointed by the American Medical Association to memorialize Congress on the cultivation of the Cinchona tree in the United States, beg leave to present the following report:—

The memorial which was prepared by your committee and indorsed by the Association was duly presented in Congress and referred to the Committee on Agriculture. No further action appears, however, to have been taken upon it.

Your committee, however, has not been idle, as will be seen by the following facts:—

A committee was appointed by the Medical Society of the State of California, at their annual meeting in 1870, to address the Legislature of California and petition that honorable body to appropriate suitable lands for the purpose. Drs. A. B. Stout and T. M. Logan were the committee selected. These gentlemen prepared a bill, which was introduced near the close of the last session of the Legislature. Owing to the fact that this bill was introduced so late in the session, it was not passed. A very favorable feeling was expressed towards the matter, however, and your committee have no doubt that a similar bill will be introduced and the lands granted.

In the mean time the chairman of your committee had opened a correspondence with the Hon. Mr. Watt, Commissioner of Agriculture. Mr. Watt gave assurance of his cordial co-operation in this matter, and has promised to supply whatever seeds may be desired.

A correspondence has also been carried on between the Commissioner of Agriculture, the State Medical Society of California and a certain F. A. C. Grebner, who has had fourteen years' experience in the cultivation of this plant in Java, and who is willing to assist in the introduction of the plant into this country.

In accordance with these facts, a second memorial has been prepared for presentation to Congress, which is herewith presented.

Bearing in mind the fact that, although Dr. Royle drew the attention of the British Government to the importance of this matter and earnestly urged their action as early as 1839, it was not until twenty years thereafter that the first step was taken in what has proved to be so successful an undertaking as the cultivation of Cinchona in India; and knowing that this matter is already receiving favor here, your committee feel that their efforts have not been entirely useless.

Your committee would further suggest that, since Dr. Antisell has been appointed upon a commission which will compel his absence from the United States for

some years, and will prevent his co-operation with the other members of the committee, the name of Dr. A. B. Stout, of San Francisco, be substituted for his, and that the committee as thus constituted be continued.

THE MEMORIAL.

To the Honorable Senate and House of Representatives of the United States of America:—

Whereas, the American Medical Association, composed of delegates appointed from the State, county and local Medical Societies throughout the whole United States, constituting therefore the highest medical authority of the country, presented to Congress nearly two years ago a memorial in which they asked Congress for the appointment of a commission of scientific men to determine certain points in connection with the cultivation of the Cinchona tree in the United States; and

Whereas, some of these points have already been determined by other experiments in this direction, and the Department of Agriculture is prepared to furnish any needed quantity of the seeds; and

Whereas, the cultivation of this tree has already been successfully tried on a large scale by the English and the Dutch Governments, and the American Medical Association believe that its cultivation by this Government would be productive of a very considerable revenue, provided that a proper soil and climatic conditions exist in the United States, which conditions the committee of the Association are convinced do exist:

Therefore, The American Medical Association would, through its committee, again respectfully ask the appointment by Congress of a commission of scientific men "to determine what portion, if any, of the public domain of the United States will produce Cinchona, and which may be set apart for the purpose."

For the Committee:

LEMUEL J. DEAL, M.D., Philadelphia, Chairman.
THOMAS M. LOGAN, M.D., Sacramento.

By order of the Association:

DAVID W. YANDELL, M.D., President.
WM. B. ATKINSON, Permanent Secretary.

VOTE OF THANKS TO COL. MORRISON

was offered by Dr. Angiar:—

Resolved, That we hereby tender our sincere thanks to Col. and Mrs. J. L. D. Morrison for the hospitalities extended to, and so greatly enjoyed by this Association, last evening.

PHONOGRAPHERS FOR THE SECTIONS.

The committee appointed to devise and recommend some plan for securing a more complete report of the doings in the several sections of the Association, respectfully report the following resolutions, and recommend their adoption:—

Resolved, 1. That the Committee of Arrangements for each annual meeting of the Association are instructed to secure the services of a sufficient number of stenographic reporters to have one in attendance on the regular sessions of each of the sections in the afternoon as well as during the general morning sessions; that the reports thus obtained be printed the same evening on slips or proof-sheets, in sufficient number to supply all the members of the Association in attendance early the following morning.

Resolved, 2. That the necessary expenses incurred in carrying into effect the foregoing resolution shall be paid from the treasury of the Association in the same manner as other bills relating to the publication of the transactions.

Resolved, 3. That the acting Secretary of each section shall keep a file of so much of the reports as relate to the business of the section to which he belongs and it shall be his duty to revise the same, carefully eliminating therefrom all that is unimportant, and arranging that which is found valuable and pertinent in proper form, he shall transmit the same to the Permanent Secretary, for the Committee of Publication, within twenty days after the adjournment of each annual session of the Association.

The report was adopted.

DR. E. L. HOWARD offered the following:—

Resolved, That the Chairmen of the various sections shall have free scope in the selection of subjects for addresses. Adopted.

THE NEXT MEETING.

The time of holding the next annual meeting in Detroit was changed to the first Tuesday in June.

After the transaction of business of minor importance the association adjoined *sine die*.

Medical Items and News.

THE NEW HEALTH BOARD of New York organized May 14, and issued some regulations abolishing the special office of Sanitary Permit Inspector, transferring the duties of the same to the Secretary of the Board.

BARON JUSTUS LIEBIG, who died at Munich, Bavaria, April 18, was a native of Darmstadt, where he was born May 12, 1803. He was educated in the "Gymnasium" of his native town, in the university of Bonn, and graduated in medicine at Erlangen. When nineteen years old he went to Paris, where he remained two years, and studied chemistry. By the influence of Humboldt he was appointed Adjunct Professor of Chemistry at Giessen when he was twenty-four. In 1826 he became professor, and established the first laboratory opened in Germany for the teaching of practical chemistry. In 1832, with Wöhler, he established the *Annalen der Pharmacie*. In 1840, in response to the invitation of the British Association, he published the work entitled "Chemistry in its application to Agriculture and Physiology." This and subsequent publications of the same nature led to the establishment of new professorships in Göttingen and Würzburg for the express purpose of facilitating the application of chemical truths to the practical arts of life. In 1842 he presented to the British Association a second report entitled "Animal Chemistry, or Chemistry in its application to Physiology and Pathology." Later, he issued two works having the same bearing, viz. "The motions of the Juices in the Animal Body," and "Researches on the Chemistry of Food." These were followed by the "Dictionary of Chemistry," which was compiled with the assistance of Wöhler, and "Letters on Modern Agriculture," published in 1859. He was created a Baron in 1845 and continued in Giessen, notwithstanding offers of professorships in other universities, until 1852, when he accepted the professorship at Munich, where he also became president of the chemical laboratory, and President of the Academy of Sciences, succeeding Thiersch. He is justly considered as one of the great benefactors of the age, both for the practical knowledge he diffused, as well as for the impulse he gave to scientific research.

DR. R. CRESSON STILES, formerly Sanitary Superintendent under the Metropolitan Board of Health, recently died at Westchester, Pa., of pneumonia, at the age of forty-three years.

Original Lectures.

ON ATROPINE.

A LECTURE DELIVERED AT THE WOMEN'S COLLEGE OF THE NEW YORK INFIRMARY.

By MARY C. PUTNAM, M.D.,

LECTURER ON MATERIA MEDICA AND THERAPEUTICS.

PART II.

THERAPEUTICAL APPLICATIONS.

. . . . . .

Besides those already well known, upon which we have insisted careful study of the physiological action of atropine is continually leading to new applications in therapeutics. I have spoken to you of the suggestion made by Harley, in regard to the use of atropine as a diuretic, and as especially adapted for the treatment of albuminuria. I have had no opportunity to test this suggestion, and do not know whether it has been tried by other physicians than Harley. Upon another theoretical deduction I will however insist, as I have begun to collect some practical evidence in its favor. The dilatation of the cerebral blood-vessels, that occurs as a secondary effect of atropine,* suggests the utility of this substance in functional cerebral anæmia. One case in which I tried atropine was that of a woman, who, three weeks after confinement, and being then in a debilitated condition, fell down a flight of stairs. She remained insensible for two hours, and for two days was unable to walk, although she had received no external injury but a bruise on the shoulder. On the fifth day she was still so giddy that she would fall unless she supported herself as she walked, and suffered from continual nausea, general muscular weakness, and occasional blurring and blackening of vision—all persistent effects of the cerebral concussion. I ordered 1-64th of a grain of atropine in solution, three times a day. The patient felt a sensible improvement in strength after each dose, as soon as its physiological effects, flushing of the face, increased dizziness, and a certain mental apprehensiveness, had passed away. On the following day, the vertigo and staggering had quite gone. In the second case, the diagnosis was more obscure. The patient presented herself at the Dispensary for Nervous Diseases, complaining of vertigo, general muscular debility, and especially paresis of the right arm, without any trembling. There was a faint blowing murmur at the apex of the heart.† Atropine was given, as an experiment, to try the effect upon the vertigo, 1-64th of a grain, at first three times, afterwards twice a day. The physiological effects, as in the first case, were extremely well marked—the flushing of the face intense, and lasted an hour. Under this treatment the vertigo entirely disappeared, and the patient gained in strength. The treatment was afterwards complicated with nutritive tonics and electricity. In a third case of cerebral and general anæmia, without any sign of local cerebral lesion, but with vertigo and floating specks before the eyes, the vertigo quite disappeared under the exclusive use of belladonna extract. The other anæmic symptoms were only relieved by blood tonics.

. . . . . .

Finally, there remains for us to say a few words on the so-called antagonism existing between belladonna and opium, in cases of poisoning. Let us notice, in the first place, that the real antagonism conceivable is not that between opium and belladonna, but between some of the effects produced by the one in the living organism, and those determined by the other. Now, there are no two substances whose entire series of physiological effects are directly opposed to each other. There are no true antidotes to poisons but such agents as effect a chemical alteration of the toxic substance, and opium and belladonna have no such mutual reaction. Moreover, it is certain that the physiological effects of the two drugs are not in all points contrasted. Mitchell,* Eulenberg,† and Harley‡ have shown, both in experiments upon animals and in observations upon man, that opium and belladonna, taken in succession, caused greater acceleration of the pulse than the belladonna alone; also that when sleep has been induced by a therapeutic dose of morphine, atropine will not disturb, but rather render it more profound. (Harley.) The anæsthesia, diminution of secretions, dysuria, produced by one of these substances, are determined by the other also, and cannot therefore be antagonized. But, on the other hand, the pupils contracted by morphine were seen to widen by atropine, or the reverse, and the respiration, slackened by morphine, to be slightly accelerated by atropine. (Erlenmeyer.) Again, though morphine prove unable to slacken a pulse accelerated by atropine, the fact that atropine accelerates a pulse that has been slackened by morphine is of the highest importance in toxicology. This may be seen even in the rabbit, although this animal is much more susceptible to morphine than to atropine. In a rabbit to whom I had given hypodermically three grains of morphine in the course of an hour, the pulse was 148, respiration twenty-four, pupils moderately contracted, animal in partial stupor, but not insensible. Three-quarters grain of atropine were injected, and in ten minutes the pulse had risen to 240, the respiration to thirty-two, though the pupils were not yet dilated. After injection of a grain and a half more, the ears became very hot, with marked dilatation of the arteries. This subsided again after the injection of one-half grain of morphine. On further injection, in divided doses of five grains of morphine, the pulse became very weak, but numbered about 200. Injections of five grs. atropine then restored dilatation of auricular arteries, and caused full dilatation of the pupils, one and three-quarter hours from the time of its first administration. The animal recovered completely. The effects upon the rabbit's ears were particularly noteworthy in this case. It corresponds to that observed on the ears of guinea-pigs by Wegner,§ and to the well-known experiments of Wharton Jones on the frog's foot with solution of atropine and Battley's solution of opium. The attempt to prove or disprove an "antagonism" between opium and belladonna frequently confuses the perception of the real questions, viz.: What physiological effects of belladonna are theoretically useful in the morbid state induced by opium? and further, to what extent do recorded cases of poison-

* On sacrificing a rabbit forty-eight hours after administration of large, but not toxic doses of atropine, the pia-mater of the brain and cord were found engorged with blood, and the arteries of the cord dilated. The initial constriction of the blood-vessels in the nerve-centres, upon which, we believe, M. Brown-Séquard bases the employment of belladonna in epilepsy, is not in contradiction with this equally indubitable fact.

† About six months afterwards this patient developed marked symptoms of *paralysie agitans*.

§ Quoted by Stellwag. Der Intrace. Druck. P. 61. Wien, 1868.

ing show that these effects have been produced? How have others been modified? Finally, what explanation can be given of the toleration shown by many patients for one poison, while they are already under the influence of the other?

This statement of the case is so simple as to almost seem superfluous, were it not evidently so often overlooked. In the experiments of Canus, so often quoted, full toxic doses of morphine and atropine were given almost simultaneously, and before the effects of morphine had had time to become manifest; in other words, before the conditions of resistance to the one poison had been developed by the other. It was to be expected, therefore, that the animal should feel the full force of both, and succumb.

For the morphine and atropine, even when acting upon the same organ, and in an opposite manner, affect different parts of its apparatus. Thus, atropine accelerates the pulse by paralyzing the peripheric extremity of the pneumogastric; morphine slackens the pulse by increasing cerebral pressure and the tonus of the central end of the pneumogastric. It is therefore easy to understand why atropine should accelerate the pulse in spite of morphine, while morphine should be unable to reduce an atropine acceleration. When the cardiac end of the pneumogastric is paralyzed, it avails little that the tonicity of the central end be increased. And when this has been increased by the opium congestion of the encephalon, the effect on the pulse is nullified so soon as the connection between the heart and brain is severed by paralysis of the pneumogastric. Again, the contraction of the pupil, which occurs after irritation of nearly all the organs of the encephalon, is also determined by the cerebral congestion of opium. While, to produce dilatation, the atropine acts on the periphery, on the iris itself, paralyzing the motor oculi nerve, and so cutting it off from the brain, and moreover contracting its blood-vessels by stimulus of the sympathetic. It is evident that both these effects on the iris might be produced, although no change had taken place in the condition of the brain, and hence dilatation of the pupil may occur after administration of atropine in opium poisoning, yet the patient remain narcotized, and finally succumb. Thus, in Blake's case,* the child, who had swallowed a teaspoonful of laudanum during convalescence from pneumonia, was treated with eighteen drops of fluid extract of belladonna in divided doses. The pupils began to dilate after the second hour, but other symptoms were aggravated, and the patient died in thirteen hours. Here the effect of the opium was much intensified by the pulmonary disease, and the dose of belladonna was small. In one of Norris' cases at the Pennsylvania Hospital, a man of 55 years, who had taken an ounce of laudanum, was treated nine hours afterwards with eight and a half grains of ext. bellad. in divided doses during three hours. At the end of this time the pupils dilated, but the general condition remained the same, the *pulse almost insensible*, and the patient died three hours later.

Again, there are cases where the dilatation of the pupils did not occur until after enormous doses of atropine have been taken, had manifested their influence in other ways, especially by the acceleration of the pulse, and been followed by a commencement of convalescence. Here the paralytic turgescence of the blood-vessels of the iris persisted after other symptoms. Thus, in one of Blondeau's cases,† a teaspoonful of laudanum had been swallowed, and occasioned drowsiness, coldness of extremities, contracted pupils, but no coma. A fluid drachm of tincture of belladonna was given in divided doses, and the pulse and temperature rose under its influence, but the pupils remained very contracted until some time after convalescence had evidently set in.

In Duncan's case,* two ounces of laudanum had been taken, and the patient was in a profound coma when the belladonna was given. This persisted after administration of an ounce of tinct. belladonna in divided doses, and the pupils continued to contract more and more. Then fifteen grains of extract bellad. were given by the rectum, and two hours afterwards the pulse rose, and the respiration became freer. Then two grains more of the extract were given, and thereupon symptoms of belladonna intoxication occurred, with, for the first time, dilatation of the pupils. Thus the turning-point in the narcotism, as manifested by the effect on the pulse and respiration, was reached before the pupils were moved, but the return of consciousness was delayed until the moment of their dilatation.

In the remarkable case related by Constantin Paul,† where the injection of an ounce of laudanum had thrown the patient into a state of intense excitement instead of coma, but accompanied by great contraction of the pupil, a large part of the laudanum had been rejected by vomiting before any belladonna was given, and the recovery would probably have taken place without any medication. But the immediate effects of the belladonna upon the symptoms were none the less striking. Twelve drops of tinct. bellad. were given every hour, and in ten minutes after each dose there was marked amelioration of the vertigo and violent nausea, though the pupils remained contracted. The opium symptoms returned in from one-half to three-quarters of an hour, to disappear again with a fresh dose of belladonna.

By narrowing the interval between the doses, the convalescence was definitely established; but not until the patient had taken over f. ʒ ij of the tincture did pallor of the face and dryness of the mouth appear, while the pupils only dilated after ingestion of nearly f. ʒ iv. The effect of opium upon the dilatation of the pupils, in cases of belladonna poisoning, is more difficult to appreciate because it is omitted from many of the histories. In Lee's,‡ however, where a child of 6 years old, poisoned with belladonna, was treated with 120 drops of laudanum, it is said that the purple flush began to fade from the face "*as* the pupils contracted." In a case recorded in the *Dublin Medical Press* for 1864, the pupils, dilated and motionless after ¼ grain of atropine, began to contract under the administration of opium that had been preceded by an emetic; at the same time the eruption began to fade. After 4 grains of opium had been taken the pupils were normal, and the patient (who was only 2½ years old) fell quietly asleep.

But on the other hand, in a case quoted in the *Union Médicale*, 1863, where from 10–15 drops of laudanum were given to a child 26 months old, poisoned by an unknown quantity of belladonna, the pupils did not contract until some time after the patient had fallen asleep, and convulsive movements had ceased. The age of the patient in this case renders this fact all the more remarkable.

Hence observation of facts justifies the expectation of theory, that in cases of poisoning by one of the two substances, opium or belladonna, the therapeutic in-

fluence of the other cannot be tested by the state of the pupils, although it is in their movements that the physiological opposition of opium and belladonna is most manifest. The pulse affords a much better test. In all cases of laudanum poisoning with a slow pulse that have recovered under the administration of belladonna, the pulse has risen in frequency and strength, and we have already pointed out several cases where this rise marked the entrance upon convalescence, and preceded, by a considerable interval, the dilatation of the pupil. In an observation in the *Bulletin de Thérapeutique*, 1865, the patient had taken 5 drachms of laudanum, and the belladonna was not given until 24 hours afterwards. At this time the effects of the poison were already attenuated, but there remained frequent vomiting, the pupils were contracted and the pulse 52. After hypodermic injection of 10 drops of a solution of atropine at 1 per cent., the vomiting instantly ceased, and the pulse rose to 68.

In another case in the *Lancet*, 1869, the patient was comatose, with stertorous breathing. The pulse was not counted until after the administration of ¼ grain of atropine, but it was then found at 160, and at the same instant the pupils dilated widely.

In one of Blondeau's cases,* ℥ijss of laudanum had thrown the patient into stupor, but not coma, and the extremities were cold, the pulse small, slow, and intermitting. After the administration of f. ʒ j of tinct. belladonna, in doses of 10 and 5 drops, the pulse rose, the extremities became warm, and convalescence progressed from this moment.†

In Anderson's case, *Edin. Monthly*, 1854, profound coma had set in, after ingestion of 9 grains of morphine, taken for delirium tremens during a period of 36 hours. The pulse was slow and very feeble. 8 drachms of tincture of belladonna were given in divided doses, f. ʒ j every half hour, and then the pulse rose, and became strong. At the same time the coma was quite dissipated. In this case the pupils dilated after the 3d dose, before any really favorable symptom was manifest, but the pulse, respiration, and consciousness were only affected at the ninth hour.

In Blondeau's second case (*Archives de Médecine*, 1865) 100 drops of tinct. belladonna were given in the course of an hour and a half, the patient remaining insensible, and the pupils contracted and motionless. After the last ten drops the pulse increased in force and frequency, (the pupils began to dilate at the same time). The recovery was assisted by frictions (?) of the thorax.

In McGee's case (*Am. J. Med. Sc.*, 1872) the coma, determined by 30 grains of opium, was combated by subcutaneous injections of one-fourth of a grain of sulph. atropia, in divided doses. The pulse rose to 140, and at the same time the pupils dilated and vomiting occurred, which emetics had previously failed to produce. There was afterwards some return of the opium symptoms, somnolence and contracted pupils, but these disappeared spontaneously, so that the recovery really dated from the rise of the pulse.

There is only one case on record where the rise of the pulse failed to initiate recovery. This is the remarkable case of Norris, at the Pennsylvania Hospital, where 75 grains of morphine had been swallowed, and marked somnolence had not occurred until four hours afterwards. Before this time the patient was treated with tannic acid, an emetic of sulph. zinc and ipecacuanha, a strong decoction of coffee, and 20 grains of extract of belladonna. As the coma advanced, 20 grains more of extract belladonna were given in two doses, the pupils dilated, the pulse rose from 80 to 120, but the somnolence persisted. The patient ultimately recovered under the free use of stimulants. This case much resembles that of Camus's rabbits, for the doses of morphine and belladonna were enormous, and administered nearly simultaneously, the first 20 grains of the extract having been given before the effects of the morphine were well developed. As in the experiments, therefore, the effects of the two poisons, instead of neutralizing each other, accumulated, and a belladonna coma succeeded to that induced by morphine.

In Norris's other case, already quoted, with a fatal issue, auscultation of the heart showed 120 pulsations, but these were so feeble that the pulse at the wrist was almost imperceptible. The atropine failed, therefore, to act as a cardiac stimulant.

In opium poisoning the great danger lies in the congestion of the brain. The contraction of the pupils, the coma, the slowness of pulse and respiration are of importance, as symptoms of this congestion, and the latter more especially, as initiating the mechanism of death. Any antagonist to opium that does not act as a chemical antidote in the stomach, must act by dissipating the cerebral congestion. Hence it is not easy to understand why Harley pronounces atropine useless because "it does not influence the respiration, where the action of opium is the most dangerous." The surest way to restore the respiration is to dissipate the cerebral congestion. And this may be done, when the paralysis is not too complete, by all agents that quicken the heart's action, and more especially accelerate the circulation in the brain. Now Harley himself admits that atropine "is one of the most powerful cardiac stimulants we possess,"—he points out the immediate relief to the nausea occasioned by therapeutical doses of morphine, from its depressant action on the vagus, that is afforded by small doses of atropine, which neutralize this action. It is not therefore true that the cerebral effects of morphine and atropine are not opposed to each other, and Harley's experiments, showing that the sleep induced by morphine is not disturbed, but rendered more profound by atropine, does not disprove their antagonism.

In the cases on record, the belladonna has been used when the patient was in one of two conditions: 1st, a state of restlessness and intense nausea; 2d, somnolence or complete coma. In the first case, the relief has always been immediate and striking. Thus in the first case of Behier,* the patient had been partially relieved by abundant spontaneous vomiting, but remained alternating between somnolence and extremely painful nausea and giddiness. One-fifth of a grain of ext. bellad. was given, and immediately these symptoms disappeared. In the case already referred to, recorded in the *Bulletin de Thérap.*, 1865, the effects of the laudanum, ingested about eighteen hours previously, were passing away, but the pulse was at 56, and there was frequent vomiting instantly checked by the injection of a very minute quantity of atropine. [See above.]

The same effect is seen in the case of Constantin Paul's, already quoted, where violent nausea and agitation constituted the main symptoms of the opium poisoning, and were strikingly relieved by belladonna. As has been said, a marked amelioration occurred ten minutes after each dose of twelve drops of

* Gaz. Hebd. 1865. This case already mentioned, in speaking of the dilatation of the pupil.

† This case is rejected by Harley, because the dose of laudanum was not excessive, and patient might have recovered spontaneously. Nevertheless it *does* show perfectly the mode of action of belladonna upon opiate symptoms, when these are not too intense to be modified.

* *Archives de Médecine*, 1864.

the tincture,—and this amelioration was permanent so soon as the interval between the doses was shortened from one hour to three-quarters, which was done after the sixth dose. It is not therefore correct to say, as Harley does in his comments on this case, that although the belladonna was given from the second hour after the poisoning, no decided effect was produced till the fifteenth hour. It was remarkable in this case, where the opium had produced agitation and not somnolence, the first phenomenon of definite recovery was sleep.

In the second class of cases, where the patient was comatose at the time of commencing the belladonna treatment, the effect of this latter is precisely measured by its effect on the pulse. If the pulse rises, the coma begins to be dissipated, and if the coma returns, the pulse has fallen again. That the effects of atropine, like those of other stimulants, should sometimes be only temporary, and unable to overcome the opium congestion, proves no more against the usefulness of atropine than against that of coffee or brandy. That, when the two poisons have been administered simultaneously or in rapid succession, the more energetic effect of atropine on the pulse may be manifested without any corresponding modification of the cerebral symptoms merely, shows that until the conditions of resistance have been developed by the action of one poison, the system is equally open to the effects of both; but that, in many cases of opium coma, belladonna has quickened the heart's action, and by so doing helped to dissipate the cerebral congestion; that, in a certain number of cases, this effect has been permanent, and even to be attributed to the belladonna alone, we think unquestionable.

Most of the recorded cases have been tabulated by Harley, and commented upon. It is worth while to pass briefly in review both the cases and the comments.

In the first three cases noticed, that of Norris,* Blake,† and one from the *Pacific Journal*, 1862, the administration of belladonna was unsuccessful. We have already noticed these cases, and pointed out that in none was the pulse perceptible *at the wrist*.‡

Concerning the case of Anderson, already quoted, Harley remarks that the coma persisted from 10 to 14 hours after the use of belladonna. But we have seen that it *was* dissipated as soon as the pulse rose.

In Motherwell's case,§ f. ℥ jss of laudanum had been taken, and twelve hours later the patient was completely comatose. The belladonna treatment was begun the 14th hour, and the coma did not begin to pass away before the 17th. But this was as soon as could be expected, and the amelioration coincided with dilatation of the pupils. [Nothing is said about the pulse.]

Now when, as in some cases considered above, the coma has been really aggravated by belladonna, the pupils *dilate*, without other sign of amelioration.

In Mussey's case,‖ there was coma and a pulse of 50, the fifth hour after ingestion of f. ℥ j of laudanum, which persisted in spite of vomiting induced by strong coffee at 3d hour. At 5th hour, grs. vj of ext. bellad. were taken; at 6th hour, f ℥ i tinct. bellad., and at 7th hour, coincidently with dilatation of the pupils, the pulse and temperature improved. By the 8th hour the skin was warm, pulse 100, and stupor had disappeared.

Harley overlooks these signs of improvement at the 7th and 8th hours, and insists on the fact that consciousness did not return till the 11th hour, 6 hours after administration of belladonna. According to him the coma was prolonged by the belladonna. But although the patient remained unconscious after some of the characteristic effects of belladonna were produced, the sleep lost its stupor and alarming character in two hours after the administration of the belladonna.

In Lee's case,* where a child of two years old was in a profound coma from laudanum, tinct. bellad., given in doses of 15 minims, produced a most decided effect. After the second dose the temperature of the skin rose; after the third the pupils became sensible to light, and the child spoke; after the fourth, the pupils suddenly dilated, the face, neck, and arms became scarlet, and the child began to laugh and cry in the first stage of atropine poisoning. Recovery was prompt. Concerning this case Harley says that the necessary details are omitted, because the quantity of laudanum was not stated. But it is unnecessary to know the exact quantity of the poison when the condition of the patient is accurately stated,—since in different individuals, and different conditions of absorption, the dose required to produce any given effect is very variable.

In Mitchell's case (*N. Y. Med. Journal*, vol. iv.), ingestion of grs. v. of sulph. morphine had not produced coma 4½ hours afterwards. The patient still answered questions correctly. It was at this time that f. ʒ vj tinct. belladonna were given, and as in Norris's case, already discussed, the stupor continued to increase till the 10th hour. During this time f. ʒ v of the tincture were given in two doses, and ½d gr. atropine in four doses. The first characteristic effect of belladonna appeared at the 10th hour after the first dose of atropine, when the pupils began to enlarge, and after the last dose there was a scarlet flush from head to foot, with dryness of the tongue, and soon the stupor was replaced by busy delirium.

This case is more interesting pathologically than therapeutically, for the amount of belladonna taken was relatively more poisonous than the five grains of morphine; and galvanism was administered between the sixth and tenth hours. The continual increase of the coma, during the administration of doses of belladonna themselves large enough to produce paralysis and coma, might be attributed to the cumulative effect of the two poisons, were it not for the absence of mydriasis. This always occurs in belladonna coma, and we have seen that it may occur when the system is saturated with belladonna, even though the narcotism first determined by opium persists. The pulse was already paralyzed and 170, before the atropine was given, so that no characteristic effect on it could be produced. It descended, probably under the influence of galvanism, to 150 and 140. As the atropine only dissipates the coma by quickening the pulse, it could not be expected therefore to have any direct effect upon the narcotism in this case. This case, and the analogous one of Norris (poisoning with seventy-five grains of morphine, stupor not till four hours afterwards) can only be explained by an arrest of absorption. It is on account of such arrest, from paralysis of the nervous, muscular, and secretive apparatus of the stomach, that spontaneous recovery has occurred after enormous doses of opium. Camus has collected a few such cases in his thesis.† The belladonna is absorbed as gradually as the opium had been, and being eliminated rapidly by the kidneys, does not accumulate in sufficient quantity to produce its own paralytic effects. Hence two facts,

† Thèses de Paris, 1865.

observable in Mitchell's case: 1st. That the first visible effects of doses large enough to produce a coma, were those that belong not to the latter, but to the initial period of intoxication, namely, a scarlet flush and busy delirium. 2d. That a large amount of urine was passed before recovery was complete. It seems probable, and the hypothesis would be easily tested by direct experiment, that the diuresis determined by the belladonna helped to eliminate the morphine from the system. The experiments of Percy show that one-quarter grain of atropine would apparently neutralize the effects of a toxic dose of morphine, when plenty of water was allowed to the animal, and free diuresis occurred; but that death would follow when, all other circumstances remaining the same, the supply of water was cut off. Hence a second, though subordinate mode of action in which atropine may be useful in opium poisoning. In cases where its influence as a cardiac stimulant cannot be exerted, or is unavailing, it may still act as a diuretic, and favor the elimination of morphine from the system. In Lucas' case,* where a child of eleven had swallowed f. ℥ jss. of laudanum, and, three hours afterwards, was almost completely comatose, Harley lays great stress on the fact that in the treatment electromagnetism was employed as well as belladonna. But this was only given in order to arouse the patient sufficiently to swallow the belladonna, and the effect of each application was most transitory. The treatment was commenced at the eighth hour, with one grain ext. belladonnæ, and this repeated six times in the course of three hours. After the fourth dose the stertor was less marked, pupils less contracted, and pulse 104. After the sixth dose the stertor quite disappeared, the face was highly flushed, the pulse at 136. The effect of the belladonna in this case seems indubitable. Here, f. ℥ jss. of laudanum, or forty-eight times the full medicinal dose, produced coma with cold extremities and livid face in three hours, showing that absorption had fully taken place. Whereas in Mitchell's observations, just discussed, after grs. v. of morphine or only thirty times medicinal dose, we have been obliged to infer that the stomach was paralyzed by the excess, and hence absorption deferred. It is certainly difficult to explain this variable action, but the fact is incontestable,—for the patient was still able to respond to questions at four and one-half hours after the ingestion of morphine. In the absence of experiments that might easily measure the rate of absorption, hypothesis is useless, and mere guessing. It cannot be said that laudanum is always absorbed more quickly than morphine, for some of the most striking cases of delay in toxic symptoms have been observed after enormous doses of laudanum.

In Duncan's case,† Harley again attributes the prolongation of the coma to the enormous doses of belladonna (f. ℥ j tincture, and grs. xvij extract) that were given. F. ℥ ij of laudanum had been swallowed, and in one and one-half hours, patient was already almost insensible to external impressions, and sunk in a comatose sleep. After the administration of the f. ℥ j of tincture in a single dose (preceded by emesis), the coma persisted, and the pupils continued to contract, the skin grew cold and covered with a viscid sweat, the pulse imperceptible. Since the pupils remained contracted, it is difficult to attribute this coma to the action of the belladonna. When the pulse is accelerated without improvement of other symptoms, it may sometimes be questioned whether the diffusion of the opium is not thereby favored, and its toxic effects increased. But in this case no effect was produced on the pulse. Moreover, if f. ℥ j of tincture had added to the opium paralysis, the additional administration of fifteen grains of extract should have been fatal; yet after this the pulse rose, and the respiration at the same time became freer. Two grains more were given, and an hour later the pupils dilated, regained their sensibility, the patient was roused from the coma, and replied to questions.

In Adamson's case* of poisoning by laudanum, f. ℥ iij tinct. belladonna given in divided doses between 3¾ and 9 hours afterwards. From the 2d to 5th hour there was no improvement, but at the 7th hour the patient was sufficiently roused to answer questions. Harley objects to this case that other means were used besides the belladonna; but these consisted exclusively of an emetic of sulph. zinc at about the 2d hour, which induced no vomiting; and in the removal of a little fluid by the stomach-pump.

In Cazin's case, quoted in the *Edin. Monthly*, 1855, f. ℥ v of laudanum had been taken in two doses. 4½ hours afterwards the patient could not be roused from stupor and the pupils were contracted to mere points. Tinct. belladonna f. ℥ j and f. ℥ ij were given between 5¼ and 5¾ hours, and at 7th hour the pulse was stronger, the pupils began to dilate, and the stupor to lessen. The improvement continued steadily to the 10th hour, which marked definite recovery.

Harley again objects that in this case electricity and emetics were also used, and that their effects complicate those of belladonna. But these means were tried about the 4th hour, and an hour afterwards, when the first dose of belladonna was given, the patient was profoundly comatose, as above described. But improvement began about an hour after last dose of belladonna.

To resume the conclusions that may be drawn from the above analysis of observations and experiments:—

1st. If very large doses of belladonna be given *before* the establishment of opium coma, still more, if given simultaneously with the opium, the paralytic effect of both poisons may be produced. [See experiments of Camus, which I have repeated with similar results—case of Norris, case of Mitchell.]

2d. When belladonna is given alone, in doses sufficient to produce coma, the pupils dilate, and the pulse is accelerated, until after the most advanced stage, when it falls. When, therefore, a coma persists in a patient who has taken both opium and belladonna, if there is dilatation of the pupils and rise of the pulse, the coma may be attributed to the accumulated effect of both poisons. But when the pulse and respiration remain slow and the pupils contracted, there is no proof that the belladonna has exerted any influence at all, and the coma must be ascribed exclusively to the effect of opium not yet counteracted by medication.

3d. It is known that after excessive doses of opium, symptoms of poisoning are often delayed longer than when smaller quantities have been taken, and the delay is attributed to temporary paralysis of absorption. This same condition partly explains the impunity with which patients plunged in opium coma bear such enormous doses of belladonna. If only small quantities are absorbed of the mass contained in the stomach, while elimination is rapidly going on by the kidneys, some time might elapse before any great amount is circulating at once in the blood.

4th. The diuresis determined by atropine favors the elimination of the opium alkaloids, and in some cases recovery seems to be mainly due to this cause.

* Med. Times and Gaz., 1865.
† *Am. Journ. Med. Sci.*, 1862.

* *British Medical Journal*, 1866.

5th. The main action is however upon the circulation. The capillaries, paralyzed and distended by opium, are directly stimulated to contract by belladonna, and at the same time the heart is quickened by being released from pressure of the pneumogastric. A double influence is therefore exerted to dissipate congestions; and as cerebral congestion lessens, the respiration, so dangerously menaced, becomes freer.

6th. Hence the therapeutic value of belladonna in any given case must be calculated exclusively from its effect on the pulse and on the kidneys. The dilatation of the pupils only shows that the system is under the influence of atropine, not that that influence is beneficial. Coma may persist, and the patient die, with dilated pupils. This is the case when animals are poisoned by toxic doses of opium and belladonna given simultaneously.

7th. In therapeutic doses, the pulse, slackened by morphine, is always accelerated by atropine, and the reverse is not true. The effect of atropine on the pulse is relatively more energetic, for reasons above detailed. But it is certain that in the majority of toxic cases recorded, the acceleration of the pulse is only produced with difficulty, and then coincides with an amelioration of the narcotic symptoms. In the one or two instances where there was not such amelioration (case of Norris), the pulse, though accelerated, remained very feeble, so that no real stimulation of the circulation was produced, but only a double paralysis. There are cases where immense doses of belladonna have been swallowed at the very moment that absorption was beginning to take place, after the temporary stupor induced by opium, and before the establishment of coma had again diminished its activity.

8th. There is nothing either in theory, or in the observation of facts to necessitate or justify the enormous doses of belladonna that have been given. It is known that the acceleration of the pulse and rise of vascular tension are produced by small doses, and the contrary effect by large. It is more rational to administer ℥xv of the tincture at intervals of a quarter or half an hour, and this treatment has been followed by more satisfactory results than the administration of f. ℥j at a dose. It is absurd to calculate the amount of belladonna needed from the amount of opium that has been swallowed, for the neutralization required is not chemical, but physiological, and to be adapted to the reactions of the organism.

9th. The toleration of such enormous doses of an opposite poison is none the less a remarkable phenomenon in the pathology of opium poisoning. When taken simultaneously, the effects are different from those noticed when the belladonna was given some time after the opium, though before the occurrence of coma. These effects are of three kinds. 1st. No toxic symptoms may be observed. [Case of Cazin,* where a liniment containing f. ʒjss. of laudanum, and f. ʒss. tincture of belladonna was swallowed, without other result than somnolence and dilatation of pupils.]

In this case the dose of belladonna was not excessive, there was abundant diuresis [the patient had previously had complete retention of urine], and this easily explains the elimination of morphine before any narcotism could be produced.

2d. There may be severe symptoms of poisoning, but followed by spontaneous recovery. [Case of Christison,—three successive injections containing each ʒj of opium, and ℥ss of belladonna leaves.] In this case there was profound coma in three hours, with dilated pupils, showing predominance of the belladonna poisoning.

3d. Coma may set in, apparently less profound than results from opium alone, but tending to a much more rapidly fatal issue. This has only been seen in experiments on animals, for in the three cases where death has followed the belladonna treatment, the doses of belladonna were much smaller than in those that recovered. (Grs. vj of extract, in Norris's case, f. ʒ ij tincture, in Blake's, and only ℥xviij in the case of the child related in the *Pacific Journal.*)

Even therefore when several hours have elapsed after the administration of belladonna, without occurrence of any perceptible amelioration, and where the therapeutic efficacy of the drug might apparently be called in question, the problem of its tolerance remains to be explained. We have suggested a partial explanation in the condition of its absorption and elimination; we do not affirm that none other is possible nor needed. But the combination of properties possessed by atropine as a diuretic, a cardiac stimulant, and stimulator of the vaso-motor nerves, affords a theoretical explanation of its action that at least lies nearer to facts positively known than the hypothesis of vague "resistance." When a certain amount of morphine had been eliminated from the system by the kidneys, the atropine is then able to exercise its most important action on the circulation, and thus directly dissipate the cerebral congestion.

It is extremely important to settle this question by examination of the urine of patients comatose from opium, and to whom atropine or belladonna has been given.*

10th. Belladonna is no "antidote" to opium, nor even to the entire series of pathological phenomena determined by that poison. Nor is this surprising, since there are no antidotes to pathological entities which do not indeed exist. But theoretically and practically it does modify some of the phenomena of opium poisoning, and may be used to advantage within the limits of the following rules.

1st. It should not be given as a prophylactic, but only to combat conditions already existing, either of restlessness, nausea and vomiting, or of somnolence, stupor or coma.

2d. It should not be given in large doses, but in small ones [℥ xv] frequently repeated.

3d. It is safe to continue the administration so long as the pupils are not dilated nor the pulse accelerated. If dilatation has taken place, yet the iris remains motionless,—if the pulse has become rapid and weak, and coma still continues unabated,—further use of atropine would only increase the mischief

4th. The use of adjuvants, as emetics, coffee, if necessary, electricity, is to be recommended as much in the belladonna treatment as in any other. The prevision of the physiological effects to be expected from belladonna enable us generally to analyze its influence, even when a complex medication has been employed.

Fibroid Tumor.—Dr. W. Mussey, of Cincinnati, Ohio (*The Clinic*), presented at the Cincinnati Academy of Medicine a fibroid growth which was removed from the left labium of a child aged two and one-half years. The tumor measured five inches in its longest, by three inches in its broadest diameter. The little patient made a very rapid recovery from the operation.

* Traité de Plantes Médicinales.

* This elimination in substance of atropine with the urine is known to be the cause of the dysuria that so frequently attends therapeutical doses.

Reports of Hospitals.

ST. LUKE'S HOSPITAL, N. Y.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

PNEUMONIA.

THE plan of treatment ordinarily adopted in the treatment of this disease is to give the patients three grains of quinine three times per day, simply for its supporting effect; if the temperature gets up to 104° or 5°, reduce it by rubbing them over with cacao butter, which operates very nicely indeed when used for that purpose, feed them well, and that is about all.

The treatment is simple, but the results are gratifying.

DELIRIUM TREMENS.

Most of these patients, it is said, will require some stimulants. A man was receiving ℥ i. three times a day. Hydrate of chloral, bromide of ammonium and potassium, and other remedies which naturally suggest themselves to the mind of the practitioner, are used if the patient requires anything besides the care and quiet of the hospital to secure sleep.

SCARLATINA.

The remedial measures employed in this affection are in keeping with the generally received doctrine that it belongs to a class of diseases called self-limited; hence all the duty of the physician consists in guiding his patients among the shoals and rocks to which they are exposed during their perilous voyage.

About ℥ i. of cacao butter is used as an unction twice a day to relieve the high temperature, and after this the symptoms are met as they arise. This article of butter of cacao receives a hearty recommendation as an agent to be used for the reduction of the temperature in this class of cases.

ACUTE ARTICULAR RHEUMATISM.

When one of these patients is brought in with joints swollen and tender and painful, and motion about suspended, in short, with all the phenomena of an attack of acute articular rheumatism, he is immediately placed upon a treatment which consists in the administration of iodide of potash in fifteen grain doses every two hours, and sulphate of quinia gr. x. alternately, every two hours.

This is continued until the acute symptoms subside. It is expected that this will take place within fifty-six hours, and is discontinued at the end of this time in case the acute symptoms do not yield. In most cases the acute symptoms are completely subdued within twenty-four or forty-eight hours, and the patients feel comparatively comfortable. This, with a certain sense of propriety, might be regarded as heroic treatment, yet the results sanction and commend its adoption. The local treatment scarcely goes beyond covering the joints with cotton. Later in the treatment colchicum enters, and is regarded as a useful adjuvant to the salts which are ordinarily employed. It is said that the salts do much better when combined with colchicum, than when they are used alone.

NIGHT SWEATS OF PHTHISIS.

A remedy commonly employed for the relief of this symptom is: Fld. Ext. Ergot in drachm doses at night. In some cases the patients vomit the remedy, but it is said to work exceedingly well in a large majority of cases.

Hydrate of chloral, given in grs. xx. doses about two hours before the time for the sweating to commence, is another plan.

Another method suggested is to awaken the patient a little before the hour at which the sweating commences, have him wash himself and take a little lunch.

SPRAINS.

These cases are immediately, as a rule, treated to a plaster of Paris splint, with the precaution taken to pad the limb well with cotton before making the application.

BURNS.

Gunpowder burns are occasionally brought in from among the quarrymen, and the application used for this class of injuries is, bichloride of mercury, one grain to the ounce of water, with the addition of one drachm of tr. benzoin. This is an old prescription here, and is supposed to be especially serviceable in connection with gunpowder burns.

Oxide of zinc ointment has the practical recommendation of an old member of the fire department.

MOSQUITO NETTING AS A SURGICAL DRESSING.

In all those cases where it is desirable to keep up support and pressure, and at the same time permit the free escape of all discharges from the wound, or ulcer, or whatever it may be, the ordinary mosquito netting used for a bandage meets all the indications. Bundling dressings are avoided in this way, the parts are kept cool, the discharge goes on unrestrained, and at the same time support is maintained. If the discharge is considerable, a pad of oakum may be placed beneath the parts to secure the discharge, thus insuring perfect cleanliness. This netting serves an admirable purpose in dressing large abscesses; for instance, when compression and free discharge are to be associated.

REDUCTION OF HIGH TEMPERATURE.

The mean normal temperature of the human body in health is laid down as 98.6° F. Anything above or below this, is to be regarded as suspicious.

When the temperature reaches 105° it is occasion for anxiety, and if associated with delirium or unconsciousness some measures must be taken to reduce it to a point somewhat nearer the normal standard without delay.

For example, a patient suffering from acute articular rheumatism has a sudden elevation of temperature to 105°, 106°, 107°, and falls into a state of unconsciousness, which is commonly the case with this elevation, must have some measures applied to reduce his temperature a number of degrees, or he will soon succumb. In such cases as these demanding active treatment, a tub of ice-cold water is placed by the patient's bed, which contains a couple of sheets. One of these sheets is wrung out and the patient immediately rolled up in it. When the temperature is as high as 105° or 6° it will become hot in a very few minutes, and then it must be changed and the other substituted for it; and this is kept up until the patient commences to complain, which is a very good indication that these measures have been carried sufficiently far. The patient is then wrapped in a dry sheet and placed in bed. This method of treatment is very often employed in this hospital, and there seems to be no other alternative in these severe cases. Unless the temperature is reduced by some means the patients almost invariably die, and this means is regarded as the most practical that can be employed.

In milder cases with less constitutional disturbance, other measures are instituted, such as sponging and the use of cacao butter as already indicated.

"There is no proof that 'cold' brings on diseases," says Wunderlich. "On the other hand, the application

of cold on febrile temperatures has proved it one of the chief antipyretic and antiphlogistic remedies, especially in typhus and exanthematic diseases."

"The benefits accruing from cold applications in fever do not depend simply upon the subtraction of an overplus of heat; the question is more complicated, and much is to be learned yet."

SUB-ACUTE PLEURISY.

Patients who present their credentials and are booked, "effusion into the pleural cavity—large quantity," are tapped at once, and placed upon tonics, quinine, and iron. Diuretics are not used with any great degree of confidence.

When the effusion is moderate tonics alone are used.

BRIGHT'S DISEASE.

The general principles of treatment embrace the administration of tonics and diuretics. The best tonics are, quinine and tr. chloride of iron; the best diuretic is thought to be the infusion of digitalis.

ERYSIPELAS.

For a local application the liq. plumbi et opii is used, and for internal administration quinine and iron, and the quinine is thought to be especially serviceable. It may have been noticed that the administration of quinine and iron in some of the hospitals is not so steadily adhered to as has been wont to be the case with the profession in general. Of their value in this disease it will be difficult to convince the profession, notwithstanding some of the cases which are treated without the administration of these remedies seem to do equally as well as those which receive it.

Progress of Medical Science.

ABSORBING POWER OF THE HUMAN SKIN.—Dr. Thomson, of Edinburgh, gives some experiments which he tried on his own person to ascertain the truth of the statements made as to the curative power of mineral water baths, depending on the absorption by the skin of certain salts and other substances which they hold in solution; and, further, to ascertain whether certain substances applied in the form of ointments, etc., pass through the skin and reach the blood before they produce any beneficial effect. His conclusions are, that not only has absorption by the skin been greatly exaggerated, but in the case of substances in aqueous solution it seems to be the exception, not the rule, for absorption to take place; and that in the case of ointments, etc., some of the substances so applied seem to be absorbed and others not.

THE PHYSIOLOGY OF THE NERVOUS SYSTEM.—The review of "Fournié on the Nervous System," in the last number of *The Journal of Psychological Medicine*, brings out the following arguments: 1st. The possibility of establishing the physiology of the nervous system upon a natural basis. 2d. To determine the nature and functions of the nervous system. 3d. The number and classification of the intrinsic functions and the functions that compose the nervous system. These subjoined facts are noted by Fournié: That the functions of the cerebral powers of relation, the cerebral functions of reproduction and nutrition, represent all the possible transformations produced in the brain in functional movements. That the brain furnishes a power that controls organic life. This he calls "incitation motrice." This "incitation motrice" is the functional product of the brain, and is also given: 1st. To the apparatus of relation. 2d. To the organ of nutrition. 3d. To the organ of reproduction. But at the same time that it gives its produced function the brain does not cease to be a living special organ, that is to say, an organ perceiving and recollecting.

FRACTURE DRESSING.—B. W. Stone, M. D., of the Western Lunatic Asylum, Hopkinsville, Ky. (*Geo. Med. Companion*), advocates the following plan of dressing for fractures for insane patients: After the fragments are brought into apposition, they are secured by two layers of the roller with splints of bookbinders board between (as ordinarily recommended); outside of this dressing is placed a wooden side-splint, deeply hollowed out on the side next to the limb, which is retained in position by straps of tinned iron or sheet iron; these encircle both the limb and splint, and are securely fastened with screws to the latter. The straps should be an inch and a half to three inches in width, and covered with cloth. In fractures of the forearm, of course, precaution should be taken to keep the two bones separate. The splint is also posterior here. This dressing, he remarks, is easily applied, the materials are cheaply obtained, is comfortably worn, and is secure against ordinary accident.

REMOVAL OF THE TONGUE.—E. M. Vassar, M.D., Cahaba, Ala. (*Geo. Med. Companion*), recently witnessed the successful removal of the tongue from a Spaniard, aged 67 years, by Dr. J. T. Gilmore, of Mobile. The operation was performed with Dr. Nott's Rectilineal Ecraseur for cancer of the tongue. Dr. Gilmore has performed this operation three times within the past two years.

CLOSURE OF THE VAGINA BY AN EXTENSIBLE HYMEN.—Dr. I. Galindo, of the city of Mexico, reports the following case: Mrs. N. N——, of nervous temperament and strumous constitution, had been married eight months. She had always enjoyed good health, and menstruated regularly and abundantly. Some months after marriage, she observed a relative scantiness of menstrual discharge; slight giddiness, loss of appetite, and a certain general bad feeling, but, attributing them to the condition of pregnancy, allowed some time to pass. The symptoms and menstrual flow continuing, she consulted a lady friend, who, after an examination, advised her to consult a physician. The physician to whom she applied felt, on introducing the finger, a membrane which, as he says, "without my reaching to the extremity or bottom of it, resisted a little, but yielded to pressure." Withdrawing his finger, the membrane adhered to it like a glove. Examination with a speculum disclosed appearances corresponding with what had been presented to the touch. A mucous membrane was seen identical with that of the vagina, elastic and entirely closed. When the next menstrual period recurred, she again visited the physician, who observed the blood passing like a sort of exudation from the whole mucous surface of the external parts, presenting great drops disseminated over the membrane. The inference was a hymen consisting of a membrane so exceedingly elastic as to permit the entrance of the penis; coition without resistance, without breaking of it, and without impeding the act. Having drawn the membrane, with pincers, outside the vagina, it was punctured with a bistoury, and at once retracted so as to form a hard roll, which offered some resistence to the free passage of the finger. Subsequently a speculum was used several times for the purpose of introducing iodine, and the hardness of the roll disap-

peared. Coition ceased to be painful, and even the use of a speculum did not annoy the patient.

Two or three months later the woman aborted; had an attack of granular metritis, and, recovering, again became pregnant. In due season she was delivered by a normal labor, excepting that owing to the smallness of the vulva the dilatation of it was tedious, and the perineum—as the doctor predicted—was ruptured.—*Observador Medico.*

Double Amputations by Chopart's and Symes' Methods. Successful Skin-Grafting. Threatened Death by Chloroform.—Dr. A. A. Shearer, A. A. Surg. U. S. A., sends us the following interesting cases:—

On Nov. 22d, 1871, William H—— was admitted to the hospital at Fort Wallace, Kansas, with both feet frozen. He had been herding cattle in the bottom of the Arkansas river, and had lost, by one disaster, all his ponies; whereupon he undertook to walk to the Kansas Pacific R. R., seventy miles north, for the purpose of procuring new supplies—an undertaking so hazardous that none who have not crossed the plains in mid-winter can form any estimate of the danger. On the second day out the thermometer suddenly sunk to — 7° and the northwest wind became a gale. Mr. H——, however, kept on against the storm, and with *very* great fortune encountered and shot a stray buffalo, on the afternoon of the third day. Almost dead with cold and thirst, he drank greedily of the blood of the animal, and without doubt this saved his life. Here he threw away his rifle, cut up his blanket and tying the pieces around his freezing feet, pushed on for life. On the evening of the fourth day he was discovered endeavoring to dig a hole in the sand thrown up alongside the railroad track, in which he might find protection against the storm. He had struck the track but twelve miles west of Wallace, to which point he intended to go when he set out.

Eighty head of strong cattle were frozen to death during the storm, in the neighborhood of Wallace, and Doctor Shearer dwells upon the above facts as furnishing an example of the wonderful powers of endurance sometimes displayed by a man whose life is at stake.

The nose, cheeks, ears and hands were badly frozen, but were perfectly restored by the measures employed, viz., the cautious application of ice-water; after which, the following liniment was used:—

R.	Tinct. iodine co.	℥	j.
	Liq. ammoniæ	℥	iss.
	Tinct. arnicæ	℥	iij.
	Ol. ricini	℥	vj.

M.

Applied to frozen parts on soft cloths, twice daily.

Life in the feet was irrevocably gone. The line of demarcation was soon established,—in the left foot, high up over the instep and including a part of the heel; in the right foot it passed just above the tarso-metatarsal articulation, the heel being left intact. Amputation above, and at the joint respectively in the two cases, was decided upon. During the performance of Syme's operation by Asst. Surgeon King, an unavoidable accident occurred in the slipping of the jointed leg of the table. The posterial tibial artery was divided above its separation. This rendered it uncertain whether it would be better to amputate above the joint or not, but the consideration that a second amputation was yet to be undergone decided in favor of completing the operation as begun, and risking the result.

The lower extremities of the malleoli were removed, and the flaps, without redundancy, brought together. Dr. Shearer then immediately operated on the other limb, above the joint; using the circular method. Nothing untoward happened to the second amputation, the wound closing completely by the twelfth day.

Violent erysipelas attacked the right stump on the fourth day, and extending to the hip, affected greatly the strength of the patient, which had already been severely taxed. The heel flap sloughed and came away on the fourteenth day. The end of the stump being covered with firm and healthy granulations, Dr. King resorted to skin-grafting, the portions of skin being taken from the patient's arms, and each about one-eighth to one-half of an inch in diameter. They were secured by isinglass plaster. Three of the grafts adhered; took on a pale blue color at first, as if about to undergo decomposition, while the non-adhering ones retained their color. The stumps healed nicely, and several months afterwards Dr. Shearer met the patient in St. Louis, walking by the aid of a light cane and artificial feet made for him by Dr. Bly, of Rochester. Owing to interference with the parts, the ball-and-socket joint peculiar to Dr. Bly's foot could only be used on the left limb. At the time of the report the patient was following his old occupation in Montana, and sat in his saddle with as much ease, and certainly with more grace than before the occurrence of his misfortune.

John D——, a citizen hunter, was admitted to the same hospital on the 26th of November, 1872, both feet being frozen. The line of demarcation in the right foot extended over the articulation of the astragulus and cuboid, and in the left foot, over the tarso-metatarsal articulation. Syme's method, with Pirigoff's modification, was employed in the amputation of the right foot, and at the completion of the operation the patient was thought to be too weak to undergo, at the time, the second amputation, which was therefore deferred until nine days later, when, his condition warranting it, the patient was again placed on the table. Chloroform was administered as before, when he speedily became pulseless and moribund. Opposite windows were opened to allow of currents of cool air; the poles of a battery were immediately applied over the heart, and artificial respiration resorted to. In a few moments slightly perceptible sighs were apparent, and these finally increased until respiration and consciousness were fully restored. Two tablespoonfuls of brandy at intervals of an hour were given for three hours, when complete anæsthesia was produced with sulphuric ether, and the foot removed by Chopart's operation. The patient rallied from the effects of the ether without a bad symptom, and on the 22d of January one stump had entirely closed, and the other discharged but little. The man will be well able, Dr. Shearer thinks, to pursue his trade—that of shoemaking—the stump admitting the use of the lapstone strap with ease.

Temperature in Uræmic and Puerperal Convulsions.—In a series of observations contributed to *L. Mouvement Médicale*, by Dr. Bourneville, with regard to the range of temperature in convulsions of uræmic origin and those of the puerperal state, the following conclusions are arrived at: 1. At the outset of an attack of uræmic convulsions, a *fall* is noticed in the previously high temperature. In puerperal eclampsia a *rise* takes place. 2. In the course of uræmia a progressive lowering of temperature takes place; whereas in eclampsia the temperature of the patient becomes more and more elevated from the outset of the attack, and that with great rapidity. 3. These differences are intensified at the moment of death—in the one case the tem-

perature falling very rapidly, even below the normal; in the other, reaching sometimes to 43° Cent.

USE OF ARSENIC IN THE TREATMENT OF CONSTIPATION.—M. Isnard recommends arsenic in the treatment of constipation, especially in the case of females. Although any preparation of arsenic seems to answer, M. Isnard prefers, ordinarily, arsenious acid. Three grains being dissolved in two and one-half pints of water, a coffee-spoonful will represent one *milligramme* of the acid. A medium dose is six to ten coffee-spoonfuls daily, in three doses, preferably taken at meal-time, in water or wine, and increased gradually in quantity.—*Le France Méd.*, April 9.

AMPUTATION OF THE ENTIRE UTERUS IN A CASE OF INVERSION.—Dr. Martino Barba, of Naples, reports a case of a woman, twenty-five years old, who suffered a complete inversion of her uterus following the delivery of her second child. Owing to the exhaustion of the patient by almost constant hemorrhage, Dr. Barba removed the uterus by means of an *écraseur* followed by a metallic ligature. The woman recovered and was discharged from the hospital on the twenty-second day after the operation.

This, according to the reporter, makes the sixty-fourth case of ablation of the inverted uterus which has been recorded, forty-four of this number having recovered. A point considered by him worthy of remark is the fact, that the operation by means of the ligature has met with greater success than any of the other modes, the uterus coming away generally by the twentieth or thirtieth day, during which time the free use of disinfectant washes is requisite.—*Le Tribune Médicale*, March 30.

A NEW METHOD OF PERFORMING AMPUTATIONS.—At a surgical *clinique* at La Pitié, Prof. Verneuil advocated the following method of removing limbs, calculated, he thought, to do away with arterial compression, whether by fingers or tourniquet, which is frequently inefficient, and is an exciting cause of phlebitis and sloughing of the integument from pressure, especially in patients who are fat. Flexion of joints, in the cases of the elbow and the knee, will frequently suffice to control hemorrhage when amputations are made below these points; but by the method advocated by Prof. Verneuil, in which the limb is treated as a tumor would be, the hemorrhage is reduced to a minimum. When antero-posterior flaps are formed, a common bistoury is all that is required for incising the soft parts, which are divided in successive layers, the blood-vessels being ligated as they are met with, and before being divided. Veins as well as arteries are closed with ligatures. The bone is divided as in the usual methods. When the principal blood-vessels are so located that they can be included in one of the flaps, it is the practice with the Professor to divide the bone before forming this flap. Twenty-one cases are reported as having been operated on by him in this manner, viz.: Eight disarticulations at the shoulder, three amputations of the thigh, two amputations of the arm, six amputations of the leg, and two coxo-femoral disarticulations. He recommends this method as having the advantages: 1, of enabling the surgeon to operate with fewer assistants; 2, the avoidance of hemorrhage; 3, obviating the risk of phlebitis from the pressure necessary to control hemorrhage.—*Gaz. Méd. de Paris*, March 29.

RENAL DISEASE IN CALCULOUS PATIENTS, AND ITS INFLUENCE ON THE CHOICE OF OPERATION.—*The British Med. Jour.* of March 8, gives an abstract of a clinical lecture by Sir Henry Thompson on this subject. The questions are, he says: If stone in the bladder is complicated by the presence of chronic renal disease, what should be done, when are we justified in operating, and what operation should we choose? Chronic renal disease he considers to be a wide term; and chronic Bright's disease is open to the same objection. First of all, malignant disease may be at once disposed of, since, if this be so advanced that a satisfactory diagnosis is possible, any operation is clearly useless. The two forms of Bright's disease which most concern us are the large, white, smooth kidney, and the granular contracted kidney—the so-called amyloid kidney being rare.

The diagnosis of Bright's disease presents no difficulty, even when complicated by the presence of stone; the low specific gravity of the urine, the presence of casts and of an amount of albumen out of proportion to the amount of pus present, decide the nature of the case at once. Next, there is what is known as the calculous kidney. Men are often met with who are frequently or almost continuously passing crystals of uric acid or small calculi. This never goes on for any length of time without damage to the kidney; on microscopic examination blood will almost always be found in the urine. Such persons are often stout, red-faced, healthy-looking rusties; but if such a man should present himself with a stone in his bladder, and says he has been accustomed to pass gravel for years, Sir Henry advises the surgeon to beware of him, for in spite of his apparent good health he will be unusually liable to severe rigors and urinary fever.

Saccharine diabetes is occasionally associated with stone. Sir Henry says he has met with two such cases, and never had any more troublesome. There was in both cases very great irritability of the bladder and of the system generally. These cases are likely to require all the care and patience the surgeon can muster.

Lastly, there is a dilated condition of the kidney and the ureters, which is due to a long-standing obstruction of the passages. This has sometimes been called "surgical kidney," which Sir Henry thinks a misnomer, since, far from being a surgical kidney, it is the consequence of a neglect of surgical measures, and never would exist if surgical aid had been afforded at the outset of the malady. This condition is most frequently met with in old cases of stricture; also in cases of enlarged prostate, large calculus, long-continued atony of the bladder, etc. Owing, then, to the presence of some obstruction to the escape of urine from the bladder, that organ becomes dilated and hypertrophied, the pressure leads to dilatation of the ureters and the pelvis of the kidneys, the secreting substance is next pressed against the capsule, and finally the whole organ may be distended into a sort of cyst. Sir Henry has seen the ureters as large as the small intestine, and contain, with the pelvis of the kidneys, thirty fluid ounces of water. A calculus by itself never produces this effect unless it is large, and not necessarily even then, since it depends on the amount of obstruction. And now comes an important fact, viz.: that this may occur without any distinct symptoms; we may suspect that this state of things is present, but cannot be absolutely sure. The patient, probably, has some cystitis, and consequently pus in his urine, but there is no more albumen present than the pus would account for; there are no casts; the urine may be of fair specific gravity, and there will even be no deficiency of urea; if there be, the patient will at once show symptoms.

A high authority abroad, he said, had stated that this condition of the kidneys can be diagnosticated by means of palpation; but he could not confirm this assertion, since it would be exceedingly difficult to detect with certainty a soft, movable, and collapsed tube like the ureter, even in a thin person: but generally these persons are in middle life, and stout, also, from confinement. The parts are not sensitive unless suppuration or a renal calculus be present. It is often possible to make a shrewd guess, but even a strong suspicion is not sufficient ground for refusing to relieve a suffering patient.

In considering the extent to which renal disease affects the prognosis of lithotrity, Sir Henry, omitting slight cases, says he has operated on three patients who were suffering with advanced chronic Bright's disease. The first was some years ago. A very pale, weak, and puffy-looking man, with a large phosphatic stone, came to him for an operation and was refused, but begged so hard that Mr. Thompson would do something for him, that the latter admitted him to hospital. After observation for three weeks, the stone was carefully crushed at the eighth sitting, allowing a good interval between them. After a stay of three months in hospital (two months longer than is usually required), the patient went out freed from his trouble, and died of the kidney disease nine months afterwards without any recurrence of the calculus. Following an operation upon a similar case, some time afterwards, the patient had some rigors, but went out at the end of ten weeks cured of the stone. Three months later he presented himself, having still a large amount of albumen in his urine, but no recurrence of the stone. Emboldened by his success, Mr. Thompson attempted a third and worse case. Everything went on well for a time, but after the fifth sitting uræmic symptoms supervened and the patient died.

Sir Henry says he has no knowledge of how many cases of mechanical dilatation of the kidney he may have operated on with success, since he knows of no means of ascertaining such condition during life, but has no doubt that this condition is present in a considerable number of the more severe cases, and instanced three cases complicated by very old and tight stricture. Under such circumstances, his plan is to tie in catheters for a week, or until he can introduce a small lithotrite, continuing the use of the catheters *in situ* until all the fragments are removed. Surgeons have advocated lithotomy in cases of calculus complicated with chronic kidney disease, as avoiding the "teasing" with instruments for several weeks; but Sir Henry is quite certain that lithotomy would certainly have killed any one of the patients above mentioned. Lithotrity was introduced fifty years ago, at which time the statistics of lithotomy were at their best and have since declined, while those of lithotrity are constantly showing better results, and he thinks that there is no doubt, with our present experience, that with a sufficiently friable stone, lithotrity, skilfully performed, is the best operation. The success of this operation is more greatly influenced by previous experience on the part of the operator than in the case of lithotomy, and Sir Henry advises those who undertake the treatment of these cases to prefer lithotomy in doubtful cases, until they have had the chance of gaining experience by crushing two or three *small* calculi.

Influence of Vapor of Ammonia in Preventing Poisoning by Fumes of Mercury.—M. Claude Bernard presented at a meeting of the Academy des Sciences, held March 16, the following facts, for M. Meyer, viz.: In shops where mercury is used in the manufacture of mirrors, it has been discovered, by accident, that the effects of this metal upon the health of the workmen can be prevented by sprinkling half a pint of the aqua ammonia of commerce upon the floor of the shop after the work of the day is ended. This course has been pursued in the manufactory of mirrors at Chauny, in France, since 1868, and the workmen have not only been thereby protected from the influence of mercurial fumes, but old workmen who had been the subjects of mercurial tremors have had their health improved. The *modus operandi* is not yet accounted for.—*Gaz. Méd. de Paris*, No. 14.

Treatment of Pyelitis by the Inhalation of Oleum Pini Ætherium.—Professor Dittel, of Vienna, has for some time past employed inhalation of oleum pini ætherium (obtained from the cones of several indigenous species of pine), with great success in cases of pyelitis. Even after the first few inhalations the characteristic smell of violets can be detected in the urine, and at the same time the pain and constantly distressing inclination to micturate cease, the amount of sediment in the urine diminishes, and soon both ease and sleep return to the patient. Inhalations are, however, only useful in cases of uncomplicated pyelitis which have not been too long neglected. In cases where there is any complication (more especially nephritis), the inhalations should only be continued so long as the inclination to micturate lessens, and the absolute quantity of sediment in the urine diminishes. Should fever be set up, and should inflammatory symptoms increase, further inhalation will only do mischief. At first the inhalations consume five minutes, and are repeated only twice daily. Should no contra-indicating head symptoms appear, the number may be increased to three or four. The cold balsamic oil is employed.—Correspondence of the *Irish Hosp. Gaz.*, April 15.

THE MEDICAL RECORD:

A SEMI-MONTHLY JOURNAL OF MEDICINE AND SURGERY.

GEORGE F. SHRADY, A.M., M.D., Editor.

Published on the 1st and 15th of each Month, by

WM. WOOD & CO., 27 Great Jones Street, N. Y.

New York, June 16, 1873.

ENDOWMENT OF MEDICAL INSTITUTIONS.

Few outside of our own profession realize that medicine is earning for itself a position among the positive sciences. Yet it is constantly making progress by the discovery and application of new facts within its own domain, and is always testing the results of all scientific investigations to see what practical bearing they may have on either the detection or the relief of disease. It is in this way that the study of optics has been the means of supplying us with the ophthalmoscope and the microscope, and in proportion as these instruments have enlarged the range of our observation we have gained in our power of diagnosis. With such improved appliances we are constantly adding to the known forms of disease or bettering our classification of old forms; and with new aids at our command and more thorough study, it is likely that we shall accomplish still greater results in the future.

We are all aware, too, that the studies in the purely scientific branches of medicine have added largely to our present knowledge. When it was observed that blood-corpuscles pass through the walls of the vessels, an important era was reached in Physiology. We were at once furnished with an explanation of many difficult questions that had long perplexed us, and scientific researches received an impulse that led to the discovery of other valuable facts of a similar nature.

Pathology, too, has won for itself recent laurels. The labors of Virchow are now recognized the world over. His classification of new growths has given to pathological researches a definiteness and accuracy that is almost mathematical. He has furnished us with a scheme by which we may decide upon the character of any tumor from the relation of its minute anatomical elements. When the clinical history is established by the collection of a sufficient number of cases, we shall have a most valuable addition to our present means of diagnosis.

Much has been done, too, in other experimental branches. Many important facts have been discovered in Pharmacology by testing the influence of drugs on the lower animals. It is well known that in some of these animals the action of reagents is quite similar to that in man. Most of the facts relating to the antagonism between poisons have been obtained in this way, and the advantages or disadvantages of certain remedies have been demonstrated pretty clearly. In fact, there is a prevailing tendency at present to rely on the observation of facts, and discard theories and speculations, and we are appreciating more thoroughly that valuable conclusions can only be reached by patient and persevering study. It is well known that Bischoff spent ten years of his life in investigating the segmentation of the egg; and Agassiz in commenting on his devotion and assiduity, said, "It is one thing to theorize about what Nature does, and another to know by virtue of patient and intense study what she really does."

Many, however, are apt to think that these investigations require comparatively small outlay, and are open to most of us. It is said that Faraday commenced his experimental labors in the kitchen. Yet it would have been impossible for him to have made his great discoveries in electricity and magnetism without ample means at his disposal, and we should hardly expect to accomplish as good results as have been reached by similar experimentalists without equal facilities. In fact, we know that Faraday had ample means at his disposal during the most active years of his life. If such studies are to be successfully prosecuted in this country, we must provide for them out of our liberality. We must not forget, too, that the labor imposed upon the instructors in such departments is engrossing and the responsibility heavy. We readily can see how incompatible such work must be with the daily routine of the practising physician. The Physiologist finds his time fully occupied if he devote himself simply to his own branch and such others as throw light upon it. So in investigating those pathological changes in the body that constitute disease, the student must have facilities for his study and for such collateral ones as minute anatomy and chemistry.

How can progress be made in Pathological Anatomy without a sacrifice of time and expenditure of material that are obviously impossible for the ordinary physician? We do not wish to underrate the value of clinical teaching. Its importance is plain, but the status of a clinical teacher is very different from that of a purely scientific one. The nature of the work that will fit the one for his post is exactly what is necessary to fit him for a high position in the community as a successful practitioner, while on the other hand success in purely scientific medicine leads to professional distinction,

but brings with it little or no pecuniary emolument. It is hardly to be expected that we shall ever see the time when these departments are self-supporting. They are quite different in this respect from our ordinary scientific schools, which fit young men for positions where they get a remuneration that bears some proportion to their proficiency. The purely scientific medical studies can hardly be remunerative in the ordinary sense of the word, but they will return us many fold the outlay, for if we are provided with the means of getting a higher education, we shall certainly make better physicians. But there is no doubt that they are necessary to our progress at this time, and should claim our support. We need for them funds to sustain them in permanent and active operation, so as to place their advantages within the reach of the student of ordinary means.

A good deal is said about the advantages of free colleges and free tuition, and it has been a popular opinion that if education were free to all, the standard would be vastly improved. Yet in this country we know that such institutions have never reached as high a degree of excellence as those that have required regular fees for attendance. Instruction in many branches of medicine does, undoubtedly, return a moderate income, and here we have no wish to see any change made; and, indeed, if at any time the requirements for graduation in our schools should be made more severe, we should be glad to know that additional fees were demanded for the additional studies.

There is another feature about most of our professional schools that is peculiar and makes them incomparable with the schools of foreign countries. Here they are mostly in the hands of private corporations, and are independent of the State or National Government. The success which they have attained, however, is a proof that private individuals are eminently capable of managing their affairs. It is highly probable that their growth would not have been as rapid and vigorous under State or National management. With the frequent changes in political power it is always likely that the original plan may be forgotten or altered at the caprice of legislators. An example of this kind has been furnished by a medical college in one of our Western cities. If support is to be given to our institutions it should come from the alumni and the public at large. None more than medical men will appreciate the advantages which the pursuit of the higher studies will give to medical schools. We should feel that there is no good reason why our facilities for instruction in this country should not be as good as in any other. The demands made upon us by the community are as exacting as they are in any part of the civilized globe, and we should be able to fill these requirements, by supplying to our students the best possible medical training. The graduates of our colleges must be looked to for active co-operation in this work. From them must emanate whatever good is to be accomplished. If they lend themselves heartily to such undertakings, by contributing their money or influence, a great deal may be done. If they are unable to give largely themselves, they can at least interest others who are ready and glad to give to any good cause.

If this subject is properly laid before the community, they will not fail to see that there is a close connection between our growth and prosperity as a nation and the sound education of our medical men, and that money given to promote such objects is as much needed as for the establishment of hospitals and other charitable institutions.

TRANSACTIONS OF THE STATE MEDICAL SOCIETY.

The Legislature of New York have failed to make an appropriation for the publication of the Transactions of the Medical Society of the State of New York. This is not so alarming a circumstance as would at first appear. The Society will now be forced to publish its Transactions at its own expense, and will doubtless take a pride in having them appear in a creditable form. We are convinced that the more independent this organization can be of legislative patronage, the better for its influence upon the profession of the State and the dignity of medicine in general.

EDUCATION OF THE PEOPLE ON MEDICAL TOPICS.

As an evidence that the leading men are ready and willing, in the face of old prejudices, to appreciate the signs of the times, by endeavoring to educate the people on medical topics, we refer with pleasure to the brilliant success of the addresses of Dr. J. Marion Sims, and Profs. R. O. Doremus and Frank H. Hamilton on Anæsthesia, recently delivered at Steinway Hall. The subject was an interesting one in any event, but was made doubly so by the masterly manner in which it was handled by the distinguished gentlemen in question.

In times gone by, any attempt to deliver such discourses in public would have subjected the perpetrators to discipline before some Committee of Ethics. Now, however, the sentiments of the profession are so much in favor of these addresses, that they are willing to encourage them in every possible way. The good which public scientific lectures accomplish is certainly enough to warrant their continuance. The people require education on medical subjects, and if the regularly educated medical man is willing to leave the field to quacks, the profession as a whole must abide by the consequences. We believe in the education of the people, and are willing to second every effort in that direction.

The Widow of the late Valentine Mott died in New York June 2, in the 77th year of her age.

Dr. Robert Loughran, of Kingston, N. Y. has been chosen President of the Ulster Co. Medical Society for the ensuing year.

Reviews and Notices of Books.

THE PRACTICE OF SURGERY. By THOS. BRYANT, F.R.C.S., Surgeon to Guy's Hospital. With five hundred and seven illustrations. Philadelphia: Henry C. Lea. 1873.

MR. BRYANT has long been known to the reading portion of the profession as an able, clear, and graphic writer upon surgical subjects. The volume before us is eminently one on the practice of surgery, and not one which treats at length on surgical pathology, though the views that are entertained upon this subject are sufficiently interspersed through the work for all practical purposes.

The extended experience of the author in the wards of Guy's Hospital as well as in private practice, and the views he entertains upon the diseases of which he treats, are concisely and pleasantly given, at the same time the opinions of others are duly respected, and quotations from their writings freely given.

The work cannot be regarded, as may be the case with many surgical text-books, as a mere compilation of the views of others, with very little original matter on the part of the compiler, for it contains more that is original than the majority of text-books which we have had the opportunity to examine within the past few months.

The chapters upon Repair and Inflammation, Traumatic Fever, Septicæmia, and Pyæmia are carefully and well written upon, while the one which treats of Tetanus, especially in regard to its treatment, is perhaps more full and modern than is contained in any text-book of its size.

On the other hand, injuries and diseases of the nerves have too little space given them. Great improvement could be made in this department if the investigations of Weir Mitchell, Morehouse, and Keene were referred to. In the treatment of Curvature of the Spine Mr. Bryant has but little faith in the various mechanical contrivances as *curative agents*; but in referring to various apparatus which must be used in conducting our treatment of these cases, the wants of the student are not properly consulted in referring to them merely by the name of the inventor. Plates of these should have been given, and directions as to how they are applied.

His chapter upon the Surgery of the Chest, especially that part which relates to wounds, is open to criticism. It hardly does the author justice. Under the head of treatment of wounds of the lung, we object to the advice given to administer antimony in half-drachm doses of the wine every three or four hours, when the pulse is rapid and respiration is increased; nor in gunshot wounds to resort to venesection, if the "lungs are engorged." Mr. Bryant quotes Dr. Macleod on this subject in saying, "that the cases of gunshot wounds of the chest that did the best in the Crimea, were those in which early and repeated bleedings were had recourse to." We believe it was Dr. Fraser who made a strong protest against this very plan of treatment, as he had observed it practised during the war in the Crimea, which caused army surgeons to abandon this pernicious practice. The results obtained in the treatment of these wounds during our late war, as exhibited in Circular No. 6 of the Surgeon-General's office, would show that venesection is uncalled for.

Aneurisms generally are well described, though with by no means the care and comprehensiveness as is seen in Mr. Erichsen's work.

Skin-grafting receives a full and interesting chapter; but due credit is not given to our own townsman, Dr. Frank H. Hamilton, in this department. We believe that Dr. H. first brought this method of closing wounds and ulcers to the notice of the profession. He first suggested it to a patient in 1847, and made the first operation on January 21st, 1854.

On the subject of diseases of the bladder our author thinks that ulceration is rarely the result of ordinary cystitis, but is due "to the frequent introduction of the catheter in the paralyzed organs, and in cases of stone." In severe forms of cystitis and ulceration, he says it is a question "whether an incision into the bladder, as for lithotomy, would not be sound practice." That this is not only sound practice, but the most judicious mode of dealing with these cases, has been fully shown by Drs. Parker, Emmet, and others of this city.

While treating of the subject of fractures of the thigh, in reference to extension and counter-extension, we are told Dr. Buck's method has "the disadvantage of not preserving sufficient immobility of the broken bones, and ought, therefore, only to be employed in conjunction with the long splint." This certainly is not in accordance with the experience of our hospital surgeons, who, we are willing to say, will show as good if not better results from the use of simple extension, as Mr. Bryant will with his long splint, with or without the addition of extension by weights.

While calling in question a few of the statements made in this book, we cannot close the notice of this excellent work without referring in terms of high praise to the chapters upon injuries of the abdomen and its viscera; the subjects of Hernia, Diseases of the Bones and Joints, as well as those of the Reproductive Organs, and affections of the Rectum.

The illustrations, which are freely scattered through the book, are in the main entirely new, taken as they are from the specimens in the museum of Guy's Hospital, and, from their character as well as in their execution tend to make the book a very attractive one.

As a text-book we cheerfully recommend it, feeling convinced that, from the subject-matter, and the concise and true way Mr. Bryant deals with his subject, it will prove a formidable rival among the numerous surgical text-books which are now offered to the student.

CLUB-FOOT: Its Causes, Pathology, and Treatment. Being the Essay to which the Jacksonian Prize for 1864, given by the Royal College of Surgeons, was awarded. By William Adams, F.R.C.S., Surgeon to the Great Northern Hospital, and to the National Hospital for the Paralyzed and Epileptic; Consulting Surgeon to the Orthopædic Hospital; late Surgeon to the Royal Orthopædic Hospital; formerly Demonstrator of Morbid Anatomy at St. Thomas' Hospital. With one hundred and six wood engravings, and six lithograph plates. Second Edition. Philadelphia: Lindsay & Blakiston. 1873.

THOUGH this work is essentially the same as the first edition, it bears the character of careful revision and many additions, especially in the chapter on the reparative process of human nucleus. Some of the plates illustrating this are from the author's special work on the subject, while others are entirely new.

The views of Mr. Adams are well known to those of the profession who are called upon to heal the deformities of which this work speaks. The views as to the pathology and treatment are in the main those that are adopted by the majority of surgeons. We fear, however, that Mr. Adams is too much wedded to tenotomy to speak without bias in reference to the treatment of these deformities by means of rubber bands. The remarks upon this latter mode of dealing with these deformities, or, as it is known now, as "Barwell's

method," as found in the second chapter of this book, appear to us to be uncalled for, and certainly the remarks in reference to Mr. Barwell are too personal, not to say in very bad taste.

With reference to the rate of extension after tenotomy, we think Mr. Adams' remarks, "that immediately a tension appears to have been the system recognized by many surgeons in Scotland and America," is partially correct with reference to American surgeons; but only in certain cases, and more chiefly when the foot is at once put up in gutta-percha splints, is the plaster bandage. When the shoe of scarpa, or some one of its modifications, is used, the rule at present in vogue on this side of the Atlantic is to allow an interval of a few days between tenotomy and the use of the shoe to elapse.

Certainly this work is written in a clear and interesting style, and by a thorough master in this department of surgery. It is a work not only valuable to the specialist, but should be read by every practitioner who has anything to do with cases of club-foot.

TRANSACTIONS OF THE MEDICAL SOCIETY OF THE COUNTY OF ALBANY, N. Y. 1851–1870. VOL. 2d. PP. 519.

THIS handsomely bound volume, edited by James S. Bailey, M.D., the indefatigable Secretary of this time-honored society, is a fitting companion to the first volume, which was edited by the late Dr. Sylvester Willard, in 1851. In it may be found *in extenso* the minutes of the Society from June 10th, 1851, up to and including June 14th, 1870, and full biographical notices of the following deceased members:—Drs. Wm. Bay, Wm. F. Carter, Mason F. Cogswell, Ira M. De Lamater, Alden March, Jas. E. Pomfret, Wm. C. Rodgers, Howard Townsend, Alfred Wands, Leonard G. Warren, Sylvester D. Willard, etc.

Since its organization, 324 members have been connected with the Society; of these, 93 have died; 7 resigned; 3 embraced homœopathy; and one was expelled. The average age of 78 of the deceased members was 52.70 years. Since 1870, semi-monthly meetings have been regularly held, which, with the preceding meetings, exhibit interesting and profitable papers and discussions, deserving a careful perusal. To the surviving members of the society the work will be specially interesting and attractive.

THE SCIENCE AND ART OF SURGERY; BEING A TREATISE ON SURGICAL INJURIES, DISEASES AND OPERATIONS. By JOHN ERIC ERICHSEN, Senior Surgeon to University College Hospital, and Holme Professor of Clinical Surgery in University College, London. A new edition, enlarged and carefully revised by the author. Illustrated by upwards of seven hundred engravings on wood. Philadelphia: Henry C. Lea. 1873.

THIS well-known work, which has been so well received as a text-book among the profession in this country, is again presented to the student and practitioner in a new form, and after a careful revision at the hands of the author. The present edition, which we believe is the sixth that the work has passed through, is issued by the publisher in two large octavo volumes of over sixteen hundred pages.

Besides considerable additional matter, many of the chapters have been re-arranged, and portions of them rewritten, and many new illustrations have been added.

Mr. Erichsen's work is too well known to require any extended notice, and having passed through so many editions, a critical review is uncalled for.

Among the many changes and additions which we now notice, we would cite the following:—

Under the head of anæsthetics a long paragraph has been given upon the bichloride of methylene.

The chapter on amputations and inarticulations has been re-arranged, and more material in the way of statistics given.

Inflammation is treated of more concisely, and the views of German pathologists properly noticed.

We regret, however, that under the head of Process of Repair, the union of wounds is treated of after the old views, rather than in accordance with the researches of Billroth and others of his school; yet while speaking of the union of fractured bones these investigators have not been forgotten.

Plaster-of-Paris dressings are referred to more *in extenso* than in previous editions, and we are pleased to find, under the head of fractures, the injuries that may follow to the nerves in these accidents are very fully set forth.

The views of Dr. Bigelow, in connection with the various dislocations of the hip, receive the attention they most assuredly merit, and here, as elsewhere through the book, American surgeons are more and more noticed. The chapter on injuries of the head, which has always been a most excellent one, is farther enriched by a paragraph upon the effects of cerebral injury on the mental powers.

Additions have also been made to the subject of injuries of the face and adjacent parts, and under this head we are gratified to see so much that is new in a general work on surgery like this, in matters relating to injuries of the eye.

Impairment of vision from spinal injury is entirely new. Two pages are given to this important subject. It would have been more appropriate, however, it appears to us, if this new matter had been found in the previous chapter upon injuries of the spine, rather than in the one devoted to injuries of the face.

To nervous diseases have been added material upon traumatic paralysis, and additions to the pathology and treatment of tetanus. Under the latter head the use of the calabar bean is mentioned, but in Mr. Erichsen's hands it has produced no appreciable good effects. We regret that no mention is made of the hydrate of chloral.

The chapter on the diseases of lymphatics and glands has been enlarged by remarks upon lymphadenoma and elephantiasis of the legs and scrotum. To the latter subject is given a table showing the results of the ligature to the femoral and external iliac arteries, in the treatment of that affection.

The whole subject of arteries has been rewritten, and is now more in accordance with advanced views than heretofore.

Chapters 43, 44, and 45, upon aneurisms and the ligation of arteries, which perhaps has been considered as the most valuable of the work, is now rendered still more so from the many valuable additions it has received, both as regards the various modes of treatment, and in the increase of statistics in the tables showing the results of the ligature when applied to the more important vessels.

These are but a few of the more important changes which are noticeable in these two handsome volumes. The whole work bears strong evidence of a careful revision, and a determination on the part of its eminent author to keep the work up in the many advances that are constantly occurring in the art and science of surgery, and maintain its high position among not only text-books, but those of reference in this department.

A System of Oral Surgery; Being a Consideration of the Diseases and Surgery of the Mouth, Jaws, and associate parts. By James E. Garretson, M.D., DD.S., Oral Surgeon to the Medical Department of the University of Pennsylvania. Phila.: J. B. Lippincott & Co. 1873. 8vo, pp. 1075.

The author of this work has succeeded in presenting to the gentlemen of the dental profession an exhaustive treatise on the subject of oral surgery. For accurate description, skilful arrangement, and thoroughness of detail it has no equal. As a text-book for the mechanical and surgical dentist it is invaluable. The large number of illustrations add not a little to the value of the work in avoiding lengthy descriptions of the various operations which the professional dentist is so constantly called upon to perform.

The Prevention and Cure of Disease; a Practical Treatise on the Nursery and Home Treatment of the Sick, &c. By Geo. H. Napheys, A.M., M.D. Springfield: W. G. Holland. 1872. 8vo, pp. 1137.

This work is professedly calculated for the non-professional reader, and will serve a good purpose. It is well written, and the suggestions thrown out and the advice given show an appreciation of the wants of such as may feel their need of being enlightened on many subjects connected with the ordinary care of the sick.

Questions on Anatomy, for the Use of Students. By Corydon L. Ford, M.D., Prof. of Anatomy in the University of Michigan.

This little volume of 136 pages forms a most excellent adjuvant in the study of anatomy. The object of the author is clearly expressed in the language of his introduction, when he says: "It is no part of my design to supersede the use of books, but on the contrary to secure the most profitable use of some good text-book in and of lecture-room instruction."

The questions partake of the author's conciseness and brilliancy in anatomical instruction. In the chapter which the author has headed "Matters pertaining to Histology," questions are introduced which not only concern histology but physiology, and the partnership thus formed is not altogether undesirable. This book may be very serviceable to students, and not unprofitable to practitioners, for two reasons: First, the questions in general are concise and well placed. Second, they give "occasion for definite answers to definite questions on practical subjects."

The Mechanism of the Ossicles of the Ear and Membrana Tympani. By H. Helmholtz, Professor of Physiology in the University of Berlin, Prussia. Translated from the German with the author's permission, by Albert H. Buck and Norman Smith, of New York.

The translators of this little monograph have done an important work in bringing before the profession a treatise, which in their own words is "the only one in any language which enters fully into the anatomical, physiological, and mathematical aspects of the question." Their work has been well done, particularly when we consider that the style of Professor Helmholtz is very condensed, and his writings are, to a foreigner, exceedingly difficult to understand.

The faults are but few in number, and might perhaps better be called indelicacies.

The work is divided into eight chapters or sections, and a great deal of space is given to the discussion of the anatomy and physiology of the middle ear. The expression "shades of vibration" has been used several times throughout the work, though it might be more correct to use the word "degrees" instead of "shades."

The *first* section is devoted to a discussion of the "results due to the small dimensions of the auditory apparatus," and on the 10th page the words "centres of excitement" had better be changed to "centres of excitation." On the 11th page, in the second footnote, the word "departure" is not a good one, and "deviation" would be better. On the 15th page, in speaking of the enormous *height* of tones, it would be smoother to substitute the expression "high degree" for "height."

The *second* section gives the anatomy of the membrana tympani, and is very carefully and clearly written. In the third paragraph on the 19th page, the second sentence is badly translated, for the possessive pronoun "its" is made to refer to the Rivinian recess, whereas it should refer to the membrana tympani. On the 20th page, in speaking of the shape of the membrana tympani, Helmholtz uses the word funnel, which seems to us too strong a term, as it is nothing more than a concavity. In the last paragraph on this same page, Helmholtz mentions an important fact, but rarely stated by other authors, viz.: that the membrana tympani owes its property of reflecting light to the fat which it contains.

In the last line of the second paragraph on the 21st page, the word "process" should be translated "spine."

The *third* section discusses the "Attachments of the Hammer," and its translation has been particularly well done. In the first line from the bottom, on the 24th page, and in the first line on the 25th page, the words "to" and "down" are superfluous, and the sentences read more smoothly without them. On the 32d page, the words "restraining band" had better be substituted for "band of restraint."

The *fourth* section tells of the attachment of the anvil, and here the translators have met with more difficulty, for there are quite a number of passages in the original which are somewhat complex. Still, it reads quite smoothly, and is much plainer than the German.

The *fifth* section describes the "movements of the Stirrup." In the first paragraph the word "anvil" has been used when the stirrup was intended. In the second paragraph the word "cotyles" is a little singular, and we think "sockets" would have been better. In this section the word "calibration" has been used several times, and apparently coined for the purpose. It would be difficult to find an exact translation of the German "calibrirung," and calibration does as well perhaps as any other.

The *sixth* section is devoted to a description of the "concerted (or better, combined) action of the bones of the ear," and is a particularly interesting one, as it contains an account of Helmholtz's own experiments. The accuracy of observation of the great scientist, and his delicate manner of manipulation, are here thoroughly manifested.

In the *seventh* section, the "Mechanism of the Membrana Tympani" is described, and here we trench upon the region of the higher mathematics. On the 54th page, in the last paragraph, the word "curve" should be "arc." Helmholtz here mentions the method of Politzer for proving that the excursion of the parts of the membrana tympani, situated between the handle of the hammer and the border of attachment, is considerably greater than that of the manubrium itself, by introducing a manometer into the external meatus. He also describes his own method of testing the acoustic action of curved membranes, for which he has invented a very simple and ingenious apparatus. He closes the monograph in the *eighth* section by a

mathematical appendix, which has particular reference to the mechanism of curved membranes, which perhaps may be of thrilling interest to any one fond of the integral calculus.

To all persons who are interested in otology and real scientific work, this little volume is well worth having.

ILLUSTRATIONS OF THE INFLUENCE OF THE MIND UPON THE BODY. By DANIEL HACK TUKE, M.D., M.R.C.P. Philadelphia: Henry C. Lea. 1873.

THE scope of this interesting work is exactly defined in the introductory chapter. "The mind acts upon the body through its three-fold states of intellect, emotion, volition. . . . . Physiologically considered, the illustrations range over the effects produced by the action of the vesicular nerves of the encephalic centres upon the sensory and motor ganglia, the centre of the sympathetic, and through the outgoing nerves upon the whole body. . . . . The cases brought together in this volume will illustrate the truth, that the mind or brain excites, perverts, or depresses the sensory, motor, vaso-motor, and trophic nerves, and through them causes changes in sensation, muscular contraction, nutrition, and secretion."

The demonstration of the dependence of all modes of psychical existence upon the nervous system, and the close connection of all parts of the nervous system with one another, gives us already the logical *à priori* basis for this proposition. On this account the practical proof afforded by the rich collection of illustrations presented by the author, is all the more interesting. It has long been shown, by the phenomena of the hallucinations of the insane, that the production of sensations may depend on a modification of sensory ganglia from within, as well as on the reception of impressions from without. The chapters on the influence of the intellect and emotions upon sensations, have almost taken for their text the assertion of John Hunter: "I am confident I can fix my attention to any part until I have sensation in that part." The influence of our mental conditions on organic functions and nutrition is of more importance than this as a basis for therapeutics, in other than purely hysterical affections, and the text of these chapters might justly be found in the sentence of Charcot: "Nothing is better established in pathology than the existence of trophical disturbance consecutive to lesions of the nerves or nervous centres." And numerous cases in Dr. Tuke's book show a precise analogy between the physical effects of an irritative thought or emotion, and an anatomically demonstrable lesion of the spinal cord or nerve centre other than the cerebral hemispheres.

CLINICAL LECTURE ON DISEASES PECULIAR TO WOMEN. By LOMBE ATTHILL, M.D. Univ. Dublin, Examiner in Midwifery, King's and Queen's College, Vice-President Dublin Obst. Society, &c., &c. Second Edition, revised and enlarged. Philadelphia, Oct. 1872. Lindsay & Blakiston. Duod., pp. 241

IT is long since we have had occasion to notice a work representing the Dublin School of Gynecology, distinguished of yore by such names as Montgomery, McClintock, and Churchill, and very worthily represented by this volume.

The first edition was published in Oct., 1871, and this second follows in less than a year, a fact which sufficiently attests the local appreciation of the work, and the author.

The book comprises fifteen clinical lectures upon the following subjects, viz.:—Instruments and manipulations, leucorrhœa, amenorrhœa, dysmenorrhœa, menorrhagia; (2), polypus, fibroid tumors, ovarian tumors; (3), inflammation of cervix, chronic inflammation of cervix, displacements, enlargements, and cancer.

In the preface to the first edition the author says: "I do not lay claim to originality in the views put forward in these lectures. I have simply endeavored in my practice to keep pace with the recent advances which have been made in the medical and surgical treatment of such cases, and I have not advocated any treatment the efficiency of which I have not thoroughly tested."

In the preface to the second edition he adds: "Keeping prominently in view the concise and practical character proposed, I have endeavored to render them as comprehensive as possible, aiming especially to express myself in the simplest and least ambiguous language."

It is not too much to say that the author has succeeded admirably in this undertaking. Perhaps because we are not again confronted with the anatomy, histology, pathology, and bibliography of the subject, so largely common to most authors, this volume, notwithstanding the disclaimer of the preface, has an air of independence and originality.

The first chapter, on leucorrhœa, clearly divides the forms due to the separate localities which give rise to the discharge—vagina, cervix and body of the uterus, and gives the physical characters which will determine the source.

To the treatment of acute vaginitis it contributes strong statements as to the value of infusion of tobacco, not commonly used among us, while it does not seem sufficiently to endorse the strong solution of nitrate of silver, so much and so successfully used here.

The recommendation of fuming nitric acid in cervical leucorrhœa we believe to be correct, and also the appreciation of depletion by the puncturator where a tumid and soft cervix reveal an attendant congestion of the whole neck.

There are good and timely words about self-abuse as the latent cause of some forms of uterine disease which baffle our best care.

Amenorrhœa is traced to its causes in defective development of the various generative organs, or the occlusion of their canals; or diathetic conditions, as phthisis, chlorosis, and plethora. The galvanic intra-uterine stem and the induced current appear in Dublin, as here, to be oftenest employed in the treatment of infantile uterus, and the fallacy of stimulating emmenagogues to be equally appreciated.

The chapter on dysmenorrhœa makes issue with those who believe it almost uniformly dependent upon permanent mechanical causes, as flexions and stricture, and while the frequent presence of these is admitted, strongly insists upon a congestive, neuralgic, and rheumatoid variety.

The necessity of enlarging the cervical canal being conceded, the author abjures all metallic dilators, prefers the laminaria to the sponge-tent, and employs the uretrotome somewhat less freely than most recent writers.

Meno- and metro-rrhagia are discussed as symptoms dependent upon debility, the lymphatic temperament, climacteric congestion, cardiac-hepatic or renal obstruction, subinvolution, and inversion of the uterus, fibroids, and cancer. In the treatment of the villous and granular conditions of the endometrium we find a method somewhat peculiar to the Dublin school—heroic in its appearance, but commended earnestly by the author after much experience of its value, as efficient, and, with proper care, innocent.

It consists in the application to the entire internal surface of the fuming nitric acid. To employ this method he dilates the cervix largely, using six or eight tents of laminaria at once, and then applies the acid on the cotton-wrapped probe with the intent of producing a shallow eschar upon all the surfaces touched. This proceeding at first strikes us as severe, but those who have observed the remarkable immunity from inconvenient symptoms which attends the use of this acid in the rectum, will not be disposed to reject the statements of the author.

In common with most gynæcologists, Dr. Atthill rejects the medicinal treatment of fibroids as nugatory, and practises upon the submucous and interstitial varieties avulsion, enucleation, and gouging aided by the hypodermic injection of ergotine. The treatment of polypus offers no novelties.

In flexions and displacements, Dr. Atthill employs the stem-pessaries for anterior, and the closed-lever of Hodges modified by Greenhalgh, in posterior curvature and prolapse! but in almost all cases treats the attendant congestion by repeated sanguineous and serous depletion, by puncturator and glycerine pledget.

The last work of Grailly Hewitt, recently noticed in these columns, assumes change of place or of axis as the primary and fundamental idea of uterine pathology.

Some ignore everything but congestion, others exaggerate interstitial hypertrophy. Atthill seems committed to no one idea, a pathologist without prejudice, an operator without a hobby. It is for this reason that we commend the book as a manual for students. The style is simple, forcible, and clear, the type and paper very good.

We do not like the duodecimo form, it is inconvenient, since almost all medical books are in octavo, and tends to the dispersion of kindred books on our shelves.

Wohler's Outlines of Organic Chemistry. By Rudolph Fittig, Ph.D., Nat. Sc.D., Professor of Chemistry, University of Tubingen. Henry C. Lea, Philadelphia. 1873. Pp. 522.

This text-book, long recognized in Germany as the leading work on this subject, and as well adapted to the use of beginners as those farther advanced, is brought to the notice of Americans through the translation of it by Ira Remsen, M.D., Ph.D., Prof. of Chemistry and Physics in Williams College, Mass, who has spent several years in Germany in perfecting himself in chemical science. To make the text of the author clear to the simplest inquirer, the translator has prefixed an introductory chapter on the "Constitution of Chemical Compounds"—an important adjunct, considering the obscurity of many of the new terms employed by the author.

As a guide to Organic Chemistry—the strict division of Chemistry into Inorganic and Organic having long passed away—its connection with instruction, and as a reference and aid in laboratory work, Prof. Wohler's Outlines are all that could be desired.

Prof. Fittig has, in this edition, entirely re-written portions of the work on account of the rapid advances in chemistry made since 1868, the date of the previous edition. More than formerly has the system of selecting the hydrocarbons been carried out, viz.: in the consideration of all the other groups of bodies, etc. The book is clearly printed on tinted paper, and being in convenient form, will be undoubtedly sought after by students and chemists who wish to know the essentials in Organic Chemistry up to the present time.

Reports of Societies.

MEDICAL LIBRARY AND JOURNAL ASSOCIATION OF NEW YORK.

Stated Reunion, held March 7th, 1873.

PLASTIC EXUDATION WITHIN THE PLEURA.

Dr. John C. Peters, President, in the Chair.

Dr. James R. Leaming read a paper on "Plastic Exudation within the Pleura—Dry Pleurisy," being the substance of his paper read at the recent meeting of the New York State Medical Society.

He showed that crackling and submucous râles are of pleural origin; that plastic exudations may be absorbed without medicine; and that fly-blistering, long continuance in close and confined air, and dosing with drugs are injurious. From twenty to forty grains of calomel, however, are useful in plastic exudations, the remedy acting as a sedative. It should be given in one dose, and not to be repeated. In some cases, to hasten absorption, the alkalies and muriate of ammonia can be employed.

In studying the etiology of pulmonary tuberculosis, plastic exudation has been too often lost sight of. He thought it was a common cause of that disease, and two-thirds of patients affected with pulmonary tuberculosis can date its commencement with the plastic exudation, to one-third who cannot; in short, plastic exudation, crippling the lung, has a powerful influence in hastening tuberculosis. Four cases were related showing the depressing tendency of plastic exudation in the lung, which were under the care of Dr. Sprague. The remedies should be antiphlogistic, tonic, and sustaining.

Dr. H. M. Sprague, of Fordham, had no doubt of the truth of Dr. Leaming's proposition, and remarked that in ninety-nine cases out of a hundred sub-crepitant râles were certainly friction murmurs, as frequently shown in autopsies. Pleurisy is a very frequent cause of phthisis, and in nine cases out of ten where one lung is affected, there will be a true friction sound of plastic pleurisy at the base of the other lung.

Dr. F. N. Otis had seen cases which corroborated the views of the speaker, which had been very interesting to him. He mentioned a case which he saw with Dr. Purdy in which the plastic exudation râle was discovered.

Dr. Peaslee stated that this point, brought out at the Academy three or four years ago by the author of the paper, would have been of immense value to him ten or fifteen years ago, when he paid more attention to the subject than at the present time. He thought that the profession were obliged to say that in the immense majority of deaths from phthisis, pleuritic inflammation must have existed. He had no reason to suppose that tubercle produced inflammation any more than pus; but inflammation could produce tubercle.

Dr. O'Sullivan said that objections could be made to the views advanced, if there was time, and an important one was the limited number of cases yet presented for their substantiation. He had resorted to counter-irritation, combined with tonics, with good effect. In regard to bronchial affections, so common in our climate, they had a serious tendency towards deposit.

The President remarked that Dr. Leaming's view was in part a favorite one of Dr. Swett, and related a

case which occurred as long ago as 1856. It made a strong impression upon him at that time, but he had departed from it. It was rare to find cases of pneumonia without attending pleurisy.

The following donation was made to the Library by Dr. Seguin: A copy each of the "Manual of Thermometry," and "The Thermometer in the Family."

The Association then adjourned.

Stated Reunion, March 14, 1873.

Dr. John C. Peters, President, in the Chair.

The President announced that Dr. Arnold had compiled nearly all of the collections of papers read before the Association since 1866, and hoped the missing ones would be handed in soon, by their authors, to complete the set.

TREATMENT OF WHOOPING-COUGH WITH QUININE.

Dr. B. F. Dawson then read a paper on "The Treatment of Whooping-Cough with Quinine," of which we give a summary.

Dr. Dawson referred, in opening, to this mode of treating pertussis as first advocated by Professor Rinz, of the University of Bonn, in 1870, through the columns of the May issue of the *American Journal of Obstetrics*. This author had shown that quinine had accomplished valuable results in his cases of the affection, which he considered to be a neurosis of the pneumogastric nerve, caused by infectious and irritating mucus that has accumulated in the pharynx and larynx; and having found by experiments that quinine destroyed, even when highly diluted, all structures found in normal mucus, he supposed that the mucus of pertussis also would be affected in a similar manner by quinine. In this he was not disappointed, the trial equalling his expectations.

The author mentioned the fungus theory of Dr. Letzerich, of Germany, also Dr. Breidenbach's mode of treatment, namely, the efficacy of the hydrochlorate of quinine—in doses of from 1¼ to 15¾ grains. He thought that with such strong testimony in favor of the quinine treatment of pertussis, it was somewhat surprising that nothing, or very little, had been done in this country to test its value.

Having opportunities for testing the value of anything new in infantile therapeutics, this mode of treatment was applied in 19 cases occurring in dispensary and private practice, and of these, 9 were selected as the most striking in their results. Out of the 19 cases the shortest cure was effected in one day, and the longest, a single case, in twenty; the next longest being twelve days. In but two cases was he disappointed in the efficacy of the quinine. They were two dispensary cases, and the failure was attributed to the negligence of those in charge of them, the quinine not being given to them as frequently as ordered. There was, however, in both these cases some palliation of the paroxysms.

In regard to the administration of so disagreeable a remedy, he found that, though frequently there was some difficulty in getting the children to take it, yet it was exceptional for them to resist after the first two or three doses, and in only a very few did it cause vomiting. The direction to give the children a piece of an orange or a little sugar five or six minutes after taking the quinine, doubtless had considerable to do with their seeming willingness to take the "bitter medicine." For his own part, he accepts the fungus theory of Dr. Letzerich as the correct explanation of pertussis, and in consequence considers it an affection of the mucous membrane of the pharynx and larynx, and the "whooping" as simply reflex; and the fact that almost all remedies given for other than their local effects, have either signally failed or but partially succeeded, he thinks strengthens this hypothesis.

Nevertheless, he does not attribute the rapid cure effected by quinine to the simple destruction of the fungus, but also to its nauseating, bitter taste. In every case of pertussis there is an abnormal secretion of a thick tenacious mucus from the mucous membrane of the pharynx (whether this secretion is due to simple catarrhal or reflex hyperæmia, or to fungoid development, it matters not), which may or may not excite a paroxysm of whooping, but which certainly aggravates and prolongs the latter, as may be proved by the fact that the paroxysms invariably cease the moment this mucus is removed either by the coughing, vomiting, or the finger. The effect of a small amount of a solution of quinine, when taken into the mouth and swallowed, is instantly, from its bitter and nauseating taste, to excite a free secretion of thin mucus from the buccal mucous membrane and the salivary glands, and thus softening, render easy of dislodgment the tenacious mucus referred to. The frequent repetition of the quinine, therefore, keeps up this free secretion, and thus prevents the mucus from becoming tenacious and difficult of dislodgment. At each act of coughing the accumulated mucus is readily loosened and expectorated, and unobstructed inspiration obtained. The rapid loosening of the cough, the briefness of the attacks in comparison with those previous to the administration of quinine, and the easy expectoration, tend to favor, he believes, the correctness of the above theory.

In closing, the speaker felt convinced that if the following rules are carefully observed, few if any will be disappointed in their results:

1st. Give the quinine—sulphate or hydrochlorate—dissolved by acid in pure water only. For children under three years, from 5 to 8 grains, and for older children and adults, from 10 to 12 grains to the ounce.

2d. Give not less than a teaspoonful *every single*, or at the longest, every two hours during the day, and whenever cough comes on in the night.

3d. Give nothing afterward for some minutes to destroy the taste or to wash out the mouth.

4. Continue giving it notwithstanding the first doses may be vomited.

5th. Be sure that the quinine is pure and thoroughly dissolved.

In the foregoing paper the author wished to be understood as advocating the value of quinine in curing the "whooping" chiefly, the cough in some of the cases lasting for some time after the whooping ceased, and which required the usual treatment for bronchial catarrh.

Dr. J. B. Reynolds, in opening the discussion, referred to the 70 or 80 cases of the affection which were reported five or six years since, in which benzoin was used with advantage, and then spoke of four recent cases placed under the influence of quinine. In two cases the remedy was given imperfectly, and in the remaining he thought there was a marked improvement, although his limited experience would cause him to hesitate before recommending it to the profession. We gave it in doses of from one to one and a half grains to the drachm of water, every hour.

Dr. P. B. Porter, in two cases reported by Dr. Dawson, coming under his observation, confirmed its value. The results were *very* good. In his own practice he was using chloral quite extensively, and for that reason had not adopted the quinine treatment yet.

Dr. F. P. Foster had had no experience with quinine, but could not believe that it was a fungoid

disease or a catarrh. His belief was that pertussis is a nervous disease. Other remedies, nitric acid for example, had achieved as good results—if taken as regularly as the quinine had been given by the author of the paper. If one large dose of belladonna, as advocated by Trousseau, was effective, he could not understand why quinine should be given frequently.

Dr. Dawson doubted the existence of a true whoop in the new-born infant.

Dr. Foster referred to authors like Watson, who confirm its existence in the infant soon after birth.

Dr. Mary C. Putnam, from an extensive reading of the theories of Binz and others, and actual computation, had found that to produce an action in the adult one hundred and twenty grains of quinine would be required. It seemed to the speaker that this enormous amount would interfere much with the explanation of its therapeutical action. That quinine may have a sedative action on the medulla could be theoretically accepted. The mode of administration recommended by the author seemed to be unobjectionable.

The Dr. inquired whether chocolate drops could be given without disadvantage just after the administration of quinine.

Dr. Dawson remarked that an interval of three or four minutes should elapse from its ministration.

Dr. Reynolds called attention to the use of quinine, in minute doses, in hay-asthma, which had been recommended by a German author—namely, one part to 750 of water thrown freely into the throat and nose in the form of spray. Dr. Sands had spoken confidently of this procedure, but where he had tried it the agent proved unsuccessful.

Dr. Hanks related his experience in giving quinine in pertussis, but never in solution. It was given in coffee, with an equal part of powdered glycyrrhiza; but he had abandoned it. As the affection was so often complicated with catarrh, pneumonia, and other diseases, it should be taken in account, when reference is made to the mode of treatment. In uncomplicated cases he he had cured it in three days with the following combination: One drop of belladonna, 14 grains of bromide of ammonium, in a teaspoonful of wild-cherry bark.

Dr. Leaming stated that a solution of nitrous acid, quinine, and iron was very efficacious, given every three or four hours, in small doses. It was a systemic disease, and might be a neuroses, although not proven. It resembled other systemic diseases, and was referable to the ganglionic system. He spoke of an epidemic, occurring in an institution under his charge, where an emulsion of castor-oil combined with belladonna was very useful in 40 cases of children. In some of these cases complicated with scarlet fever, after the latter had run its course, the cough again returned.

Dr. Janvrin had used quinine only in a few cases, and then in conjunction with his favorite remedies, hydrocyanic acid and belladonna. He thought the remedy was a beneficial adjunct. In regard to hay-fever, and its treatment with the spray-producer, he could not recommend it, as in his experience it had no effect.

The President cited Virchow as an authority for the administration of large doses of quinine in hay-fever.

As pertussis was an infectious and contagious disease, practitioners must bear in mind, that disinfectants were important agents in cutting it short. The chloride and sulphate of soda were of great service. The tenacious mucus was to be overcome by alkalies—the cough being loosened by these remedies. The old mixture of potash and cochineal had stood the test of time. He then spoke of spasm of the glottis, and said that many, like Dr. Frank Smith, preferred to narcotize their patients enough to keep them drowsy. Aconinum has great paralyzing influences on the muscular system; it is to be preferred to other remedies. The extract can now be relied on. He has seen the disease subside in two or three days under the use of prussic acid. All the astringents, such as tannin, acetate of lead, oxide of zinc, and alum are advocated; the acetate of lead could be particularly recommended for neutralizing the mucus. The tonic remedies have only until recently been used in old, broken down cases.

Dr. Jerome C. Smith confessed, after using during the past nineteen years all the remedies, that he did not treat pertussis better now than when he first started in practice. The first remedy used by him was asafœtida. He would be pleased to see such favorable results in his practice with quinine, as had been narrated by Dr. Dawson, and should use it at the first opportunity.

Dr. Reynolds had used asafœtida and all other remedies with the exception of chloral. As a general rule, he gives iron to build up the blood, and then, where there are no complications, invariably sends them out of doors; his experience shows that patients cough less out of doors than in the house. They should be well fed.

Dr. Dawson inquired if, in his three cases, he did not get better results with quinine than from anything else.

Dr. Reynolds thought that as good results were obtained by benzoin, as the character of the disease changes constantly. This season children affected were more restless than usual, and the bronchitis is more than ordinarily marked.

The Association then adjourned.

Correspondence.

MEDICAL SOCIETY OF HUDSON CO., N. J.

To the Editor of the Medical Record.

Sir:—Under the head of Medical Items and News, published in your number of April 15, 1873, you report that at the regular meeting of the District Medical Society, County of Hudson, New Jersey, held at the Court-House, April 1, 1873, an election was held to fill vacancies, and that a President, Vice-President, Treasurer and Reporter were elected to fill such vacancies.

I will first call your attention to the fact that in your issue of Feb. 15 was published a correct list of the officers of the Society elected at the annual meeting, held Dec. 3d, 1872; since then no vacancies have occurred in the Society, except that the Secretary elected at the annual meeting, was deposed at the regular meeting, held May 6; and again, the District Medical Society, County of Hudson, did not hold its meeting at the Court-House on April 1, but convened on that day at St. Mary's Hospital, Hoboken, where the regular session of the Society was held.

An attempt was made to create a division in the District Society and to gain a representation in the Medical Society of New Jersey; but the State Society, which adjourned yesterday, recognized only the offi-

cers and delegates elected at the annual meeting of the County Society, held in Dec. last.

You will oblige the District Medical Society by making the necessary correction.

Yours truly,

M. A. Miller, M.D.,
President Dist. Med. Soc., County of Hudson.

Jersey City, N. J., May 29, 1873.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from May 5, 1873, to June 4, 1873.

Milhau, J. J., Surgeon.—Relieved from duty in Department of the South and assigned to duty as Post Surgeon at Fort Columbus, N. Y. H. S. O. 94, A. G. O., May 7, 1873.

Smith, A. K., Surgeon.—When relieved by Assistant Surgeon Lippincott, to comply with orders from War Department. S. O. 86, Department of the South, May 2, 1873.

Alden, C. H., Surgeon.—When relieved by Assistant Surgeon White to avail himself of the leave of absence granted in S. O. 56, C. S., A. G. O. S. O. 52, Department of the Lakes, May 6, 1873.

Fryer, B. E., Assistant Surgeon.—When relieved by Assistant Surgeon Moffatt, to comply with orders from War Department. S. O. 65, Department of the Missouri, April 30, 1873.

Weeds, J. F., Surgeon.—When relieved by Assistant Surgeon Caldwell, to comply with orders from War Department. S. O. 86, C. S., Department of the South.

Knickerbocker, B., Assistant Surgeon.—Relieved from duty in Department of the South, and to report in person to the Commanding General Department of the Columbia, for assigment to duty. S. O. 94, C. S., A. G. O.

Phillips, H. J., Assistant Surgeon.—To report in person for duty to the Commanding Officer of the Modoc Expedition. S. O. 51, Department of the Columbia, May 2, 1873.

Caldwell, D. G., Assistant Surgeon.—Assigned to duty at Nashville, Tenn. S. O. 86, C. S., Department of the South.

Lippincott, H., Assistant Surgeon.—Assigned to duty at McPherson Barracks, Atlanta, Ga. S. O. 86, C. S., Department of the South.

White, R. H., Assistant Surgeon.—Assigned to duty at Fort Porter, N. Y. S. O. 52, C. S., Department of the Lakes.

Wilson, W. J., Assistant Surgeon.—Granted leave of absence for thirty days on Surgeon's certificate of disability. S. O. 66, Department of the Missouri, May 3, 1873.

Moffatt, P., Assistant Surgeon.—Assigned to temporary duty at Fort Union, N. M. S. O. 65, C. S., Department of the Missouri.

King, J. H. T., Assistant Surgeon.—Assigned to duty at Fort Brady, Mich. S. O. 53, Department of the Lakes, May 9, 1873.

Ewen, C., Assistant Surgeon.—Granted leave of absence for thirty days. S. O. 78, Department of the Platt, May 12, 1873.

Irwin, B. J. D., Surgeon.—Granted leave of absence for twenty days. S. O. 72, Department of the Missouri, May 14, 1873.

Fryer, B. E., Surgeon.—When relieved by Assistant Surgeon Moffatt, to comply with orders received from War Department. S. O. 42, District of New Mexico, May 15, 1873.

Frantz, J. H., Surgeon.—Granted leave of absence for 60 days. S. O. 27, Military Division of the South, May 20, 1873.

Weeds, J. F., Surgeon.—Assigned to duty as Post Surgeon at Fort Randall, D. T. S. O. 103, Department of Dakota, May 17, 1873.

Hartsuff, A., Assistant Surgeon.—Relieved from duty in Department of the Lakes, and assigned to duty in Department of the Platte. S. O. 105, A. G. O., May 26, 1873.

Greenleaf, Chas. R., Assistant Surgeon.—When relieved by Assistant Surgeon Huntington, to comply with orders received from War Department. S. O. 60, Department of the Columbia, May 23, 1873.

Knickerbocker, B., Assistant Surgeon.—When relieved by Assistant Surgeon Cronkhite, to comply with orders received from War Department. S. O. 96, Department of the South, May 17, 1873.

Middleton, J. V. D., Assistant Surgeon.—Assigned to duty as Post Surgeon at Fort Bufort, D. T. S. O. 107, Department of Dakota, May 22, 1873.

Huntington, D. L., Assistant Surgeon.—Assigned to duty as Post Surgeon at Fort Lapwoe, Idaho Ty. S. O. 60, C. S., Department of the Columbia.

Brewer, Jno. W., Assistant Surgeon.—To report to Commanding General, Department of the East, for assignment to duty. S. O. 110, A. G. O., June 2, 1873.

Cronkhite, H. M., Assistant Surgeon.—Assigned to duty at Oglethorpe Barracks, Savannah, Ga. S. O. 96, C. S., Department of the South.

Heizmann, C. L., Assistant Surgeon.—Assigned to duty with the Expedition for the reconnoissance of North-Western Wyoming. S. O. 80, Department of the Platte, May 15, 1873.

Moffatt, P., Assistant Surgeon.—Assigned to temporary duty at Fort Union, N. M. S. O. 42, C. S., District of New Mexico.

Styer, Chas., Assistant Surgeon.—Assigned to duty as Post Surgeon at Chattanooga, Tenn. S. O. 102, Department of the South, May 27, 1873.

Yeomans, A. A., Assistant Surgeon.—Relieved from duty in Department of the East, and assigned to duty in Department of Missouri. S. O. 105, C. S., A. G. O.

An Aged Maid of Honor.—Madame Melgueil, one of Queen Marie Antoinette's maids of honor, who accompanied her unfortunate friend to the foot of the scaffold, has just died at the age of 102 years.

Medical Society of the County of Kings.—Officers for 1873:—*President:* Wm. Henry Thayer.* *Vice-President:* Benj. A. Segur. *Secretary:* Richard M. Wyckoff.* *Assistant Secretary:* Audley Haslett.* *Treasurer:* J. S. Prout.* *Librarian:* William W. Reese.* *Censors:* S. G. Armor,* J. H. H. Burge,* C. H. Gibberson,* H. G. Newton,* E. R. Squibb. *Orator:* Alexander Hutchins. *Alternate Orator:* J. H. Raymond.

Medical Items and News.

Dr. Charles S. Bull, late of this city, has removed to St. Louis, Mo.

The London Practitioner has been enlarged by the addition of a department on Public Health.

The British Medical Association holds its next annual meeting in London during the first week of August.

New York Academy of Medicine, June 19, Dr. R. J. O'Sullivan will read a paper on the Hygiene of Primary Schools.

Foster.—Dr. S. Conant Foster, late of New York City, died in Nassau, N. P., April 18, 1873, in the 56th year of his age.

The Public Baths of New York were opened June 1st, for the season. Why not have more than two of these bathing establishments?

Puerperal Fever has been so prevalent in New York of late as to compel certain of our practitioners to send their patients out of town to be confined.

Royal College of Physicians, London.—Dr. Burrows has been re-elected President of the College—an office which he has filled for the last four years.

Physician to the Sultan.—Dr. Mary L. Wadsworth, a graduate of Mount Holyoke Seminary, and a former practitioner in Springfield, Mass, is now family physician to the Sultan of Turkey.

Medical Department, University of New York.—Professor Charles L. Ives, of Yale College, has been elected to fill the chair of Diseases of the Mind and Nervous System, in the Medical Department of the University of the City of New York.

Dr. W. M. Chamberlain, of New York, and Dr. J. Solis Cohen, of Philadelphia, members of the Record Staff, will be absent in Europe during the present summer. We are happy to state that our readers will hear from them from time to time on medical topics.

Dr. R. W. Taylor read a paper before the Public Health Association, Thursday, June 12th, 1873, on *Syphilitic Contagion communicated in the Rite of Circumcision.* This paper is based upon the observation of a series of cases of syphilis in children from circumcision, which were brought to the notice of the Board of Health of this City.

Propagation of Puerperal Fever.—Within the past few days we have been reading a brochure by the late Prof. Joseph M. Smith upon this subject, with so much profit that we would commend the same course to our readers. It is more than ordinarily interesting in view of the prevalence of puerperal fever at this time in our midst. The brochure in question first appeared as an original article in the *New York Journal of Medicine*, Sept. 1857.

Josiah Clark Nott, M.D., whose death we have previously noticed, was a son of Abraham Nott, a distinguished judge of South Carolina, and was born in Columbia, S. C., 31st March, 1804. He received a collegiate education and graduated in arts at South Carolina College in 1824, and in medicine at the University of Pennsylvania in 1827, having defended a thesis on "Costiveness."

Immediately after graduating he was appointed demonstrator of anatomy under Dr. Physic, who was then professor of anatomy in the University. For two years he discharged the duties of the appointment, when his health failing, and showing indications of pulmonary tuberculosis, he removed South to the place of his birth. In 1835 he visited Europe, and on his return in 1837, settled in the practice of medicine at Mobile, Ala. Here he became distinguished in the departments of both medicine and surgery. In 1857 he was appointed Professor of Anatomy in the medical department of the University of Louisiana, and subsequently to the chair of Surgery in the Medical College of Alabama.

His literary labor in the various departments of science, and particularly in medicine and ethnology, has immortalized his name. He contributed largely to the medical periodicals of the day; and from his pen the following works have been published:—

In 1844, "The Natural History of the Caucasian and Negro Races."

In 1849, "The Connection between the Biblical and Physical History of Man."

In 1850, "The Physical History of the Jewish Race."

In 1854, "The Types of Mankind;" and in 1857, "The Indigenous Races of the Earth." The last two works in connection with George R. Glidden and others.

In 1866, "Contributions to Bone and Nerve Surgery." This last book was mainly the result of his personal observations in the late war.

In 1868 he came to this city to reside; and in 1871, became a fellow of this Academy. Last spring he was seized with hæmoptysis, which compelled him to leave the city; last November he removed to Mobile, hoping to obtain relief from the pulmonary trouble which finally closed his earthly career on the 31st of March last. Of his professional labors among us there are those present who can speak better than myself. S. S. P.

The following resolutions were presented by a committee of the New York Obstetrical Society, appointed at the meeting subsequent to the death of Dr. J. C. Nott:

Whereas, It has pleased Almighty God of His infinite wisdom to remove from our midst our late fellow and former President, Dr. Josiah C. Nott; therefore, be it

Resolved, That, while we bow in submission to His will, we feel that in the death of our late beloved associate we have sustained a loss rendered irreparable by his rare professional and scholastic acquirements, his genial and fascinating social qualities, and his simple, honest nature.

Resolved, That, by his valuable contributions to the profession which he loved and honored, Dr. Nott had rendered himself a member of whom we may all feel proud, and whose loss the science of medicine may well deplore.

Resolved, That, in his relations with and conduct towards his professional brethren, illustrated by a long and active career, he has left us an example worthy of imitation.

Resolved, That we tender to his bereaved family our most sincere and heartfelt sympathy in their sorrow.

Resolved, That a copy of these resolutions be sent to his family, and be published in the medical journals of this country.

Signed: J. Marion Sims, M.D.
T. Gaillard Thomas, M.D.
Thos. Addis Emmet, M.D.

Chas. S. Ward, M.D. *Secretary, N. Y. O. S.*

Jenner.—Sir William Jenner has been elected President of the London Pathological Society.

Medical Department of Life Insurance.

LONGEVITY;

OR, THE RELATIVE VIABILITY OF THE SEXES: PARTICULARLY WITH REGARD TO THE RELATIVE LIABILITY TO THE INHERITANCE OF CERTAIN TRANSMITTED DISEASES,—CONSIDERED IN RELATION TO THE SELECTION OF LIFE INSURANCE RISKS, WITH A VIEW OF EXHIBITING THE UNJUSTNESS OF THE PRACTICE OF CHARGING HIGHER RATES FOR WOMEN. ILLUSTRATED, IN PART, BY THE STATISTICS OF PHILADELPHIA, FOR THE ELEVEN YEARS ENDING 1871.*

By JOHN STOCKTON HOUGH, M.D.

Part I.

"Feminæ præ Viris Longevieres."†

From all time and in all ages, physicians, physiologists, and philosophers have declared that woman is but undeveloped man, *not less perfect* than the man *as woman*, but less perfect in a developmental or evolutionary point of view, taking man as the type of the race; or even taking an intermediate (hermaphroditic) sexual organization as the type, in a purely physical aspect, the woman is as far below it as the man is above it. All the latest discoveries and experiments, added to what has hitherto been accepted as true, fully confirm this opinion, which is associated with the names of Aristotle, Humboldt, Harvey, Walther, Wagner, Kessler, Tiedeman, and innumerable other high authorities in all parts of the world, notwithstanding the assertions and allegations of a few uninformed erratic Agrippæan philosophers to the contrary.

By the man being more highly developed than the woman, we mean that his organs are more highly developed, more elaborated, the tissues more attenuated, more thoroughly evolved from an embryonal condition, while the woman retains in a greater degree the embryonal and infantile rotundity, softness, texture, flexibility, elasticity, size, weight, stature, chemical composition and physical constitution of her organs, tissues, and fluids. Want of space and time forbid elaborate details of explanation and proof of this position.

To epitomize the female life, we may say:—She is conceived from an egg less mature (less highly developed); she is extruded after a shorter period of gestation, by a shorter and more easy labor, reaches puberty from one to three years sooner, reaches maturity five years earlier than the man. Though she surpasses man in the rapidity of her development, is subjected to the dangers incident to childbirth, yet notwithstanding this she has a greater viability than man, or is, in other words, longer-lived than he is from the moment of her conception, at the time of her birth,‡ and at other ages. She has a greater tenacity of life, does not succumb to certain deleterious influences so easily as man. It is well known that mares endure hardships, fatigue, wear longer and better than horses, or even geldings; they are "tougher," as the horsemen say. Horses "founder" more frequently than mares—just as men have gout more frequently than women.

"Cavalry officers in the late war found out the wisdom of selecting mares for arduous services; and we all know what a miserably dull animal the unsexed ox becomes." *

As "hunger is a want less imperious in woman" than in man, she will not starve so soon as man. One-fifth less aliment is required for women than for men, as observed in hospitals and prisons.

Maux† has remarked, in dioecious plants, that the females resist injuries better than males; and Mr. Meehan‡ has observed that female plants are less affected by frost than males. This is the more surprising from the fact, as shown by Girou,§ that the fibrous system prevails in male plants, and the vascular in females. In the animal kingdom Burdach‖ has pointed out the predominance of the vascular system in males and the glandular system in females.

Whether the man is *naturally* (in a state of nature) longer-lived than the woman is a question which it is very difficult to decide. I am inclined to believe that *originally*, and in a non-civilized state, men exceeded women in length of years; but, by the nature of their sphere of action in the social compact, by the greater anxiety and mental strain incident to their avocations, by being at the head of the family, by engaging in more hazardous pursuits, by being led into more vices, dissipations and debaucheries than women, by their greater participation in the physical and physiological effects of degeneration in the race, they are in reality shorter-lived than women.•

"At the commencement of the division (of sexes), the female will be first provided for; and in the great struggle for life, all other things being equal, the chances are greatly in her favor. . . . In *vitality*, if by that we may understand the ability to endure circumstances tending to destroy life, he is below her." * *

It would seem, if we followed out the analogy in the greater rapidity of the development of the woman at the various epochs mentioned, that she ought to grow old sooner,†† and indeed die at an earlier age than the man. Though there is some difference of opinion as to the relative longevity of man and woman, yet most good authorities claim that women have a greater longevity than men. It is alleged by most authors, and is indeed proverbial, that marriage lengthens life, but none have explained how or why it does so by any physiological process. I would venture to suggest, therefore, that during each pregnancy the woman *ceases developing*, though she may grow, and as a consequence loses nine months at each pregnancy; and as women have on an average four or five children, they lose from three to five years' development during their pregnancies and lactation. If they do not develop during lactation, it is safe to say that they lose at least eight years, in which, were they not pregnant

---

* The writer, in the course of this article, has enunciated theories, some of which are novel and original, and while he fully believes them to be true, he desires it to be distinctly understood that they are not *necessarily* recognized by scientists generally, and further, the scope of this article gives him no opportunity to prove his position, which he hopes to do at some future time.

‡ Dr. *J. M. Toner*, in calling attention to one of his diagrams, says it "shows a fact that I am unable to assign any satisfactory reason for; that is, the great excess of male over female deaths under 1 year, and indeed during the entire infantile period under 5 years. According to this showing, the excess of male deaths under 1 year is more than treble the proportion of the excess of male births reported in the United States." ‖ Physiologie, v. ii.

• The fact, as maintained by some, that female fetuses sap the vitality of the mother more than males, may have some influence on their higher degree of VITALITY; this will be treated in a subsequent paper on "The Cause of Rotation of the Sexes."

* * *Thomas Meehan*, "Old and New," February, 1872, p. 17.

†† "According to Pliny (Hist. Nat., B. vii. c. 4 (5), female children are matured more quickly than males, and become old sooner. 'Fœminas gigni celerius quam mares.' Harduin interprets the phrase, 'Crescere pertici, vigere, adolescere.' Cuvier translates it, 'Les filles sont parvenues moins longtemps par leur mere; the daughters are carried a shorter time by their mothers.'" Bostock's Physiology.

or nursing, they would be growing physically as well as really old.

Aristotle says, "They (females) grow old more rapidly, above all if, as we have already remarked, they have many children." *

Dr. Wilks, of Guy's Hospital, in the *Lancet* for January, 1869 (?), calls attention to the fact that a severe diarrhœa may check the growth of the finger-nails, which is indicated by a furrow in the nail, caused by arrest of the nutritive process. So it would *seem* as if the occasional presence of certain morbid conditions was instrumental in lengthening life.

All farmers and stock-raisers know very well that if a heifer become pregnant before she is mature, *i. e.*, about three years old, particularly if it be before the second year is reached, she not only ceases development during gestation, but the possibility of future growth and development is forever after impaired, if not made impossible, though pregnancy may not occur again; such a heifer is said to be "stunted" not only in growth but in development, and retains in size and appearance a greater resemblance to her condition as a calf than she would had she not brought forth until the third year. Whether this premature pregnancy has been observed to lengthen life, I have not been able to learn.

"There are no cultivators who ignore the fact that young females cease to increase after they have given birth to young; and that suckling is still more prejudicial than gestation to their increase in size." †

"It should be emphatically stated," says Dr. Smith, "that child-bearing is not a disease, nor does it less n the 'expectation' of life; on the other hand, life is extended by the effects of pregnancy and child-birth.

"In that relation (marriage), women, on an average, outlive men; and widows live to be older than widowers." ‡

On the whole, then, child-bearing lengthens life, despite the few deaths incident to parturition.

Dr. Casper, after comparing the relative viability of men and women at different ages in the married state, with the unmarried of both sexes, concludes that "le mariage exercise une action favorable encore plus marquée sur la vie de l'homme que sur celle de la femme." §

"Celibacy is more injurious to the woman than to the man; it frequently occasions amenorrhœa, scirrhus, cancer, and a death more premature; in convent-life there are more unhealthy women than men. Fecundation and pregnancy act as fortifiers in the woman, and the mothers of numerous children are in general the most healthy, and live the longest; the sterile woman is more unhappy than the childless man."

The man is shorter-lived than the woman, ¶ notwithstanding the dangers incident to her sexual life, which are peculiar to her, some of them even being without an analogue in the man. Her dangers are greater at the epoch of puberty, during pregnancy, parturition, accouchement, and the extinction of the procreative faculty. The male deer is ** shorter-lived than the female. The females of the pinecrons and the entomostracea are longer-lived than the males. The female bee lives for several years, while the male perishes within a year of his birth.

The woman only acquires the full enjoyment of her force after marriage and pregnancy; it is before marriage that the man has more vigor.*

According to Quetelet † the viability of males and females is about the same on the approach of puberty, or about the 13th year. From this point to about the 18th year the mortality of the woman is the greater. After being equal at the 18th year, the mortality of the man rapidly increases until the 25th year, when it is at its maximum. Then it rises with equal rapidity to the 28th year, when both sexes are again equal. From the 28th to the 50th year the mortality of the woman is considerably greater than that of the man. After the 50th year they both appear to be the same.

This last statement would seem to be directly opposed to the facts as set forth in another part of this paper, wherein the author shows that women have in general after the 5th year a higher viability than men. There are certainly, in this country, more females than males attaining the ages from 60 to 100 years, and the mortality of females from conditions incident to child-bearing is probably counterbalanced by the excess of males in the mortality from intemperance, suicide, murder, injuries, and in the army.

"Carus ‡ remarks that the male fœtuses are oftener the subjects of asphyxia when they come into the world than females, and that they experience more pain and are more difficult to raise from a state of apparent death. Cyanosis is much more rare in the woman than in the man, hemoptysis also presents less danger in her, and leads less frequently to pulmonary phthisis." § Yet the lungs are larger both absolutely and relatively in man than in woman.

M. Alph. Devergie, in his able paper on "Asphyxie par charbon," ‖ says, in 1834–35 there were 360 cases of asphyxia by carbonaceous gases, and among this number 19 cases were of two persons together (man and woman). There were only three examples among these 19 cases, of which one of the two persons were restored to life, and they were all women. The proportion of women saved is much more considerable than that of men. Of 184 cases occurring in 1835, 18 women were saved out of 73, or ¼, and only 19 out of 83 men, or about ⅕.

Some persons might argue from the above fact that the woman was physically stronger than the man, but this is evidently not the case, as everybody knows that time and time again two persons of the same sex, one sick, the other well, have been sleeping in a room filled with the gases arising from the partial combustion of carbon, when the well one was fatally poisoned and the feeble sick one escaped. The true explanation of the matter is, that the more highly developed or healthy person requires more oxygen, and is more sensible to the influence of noxious gases.

In England (1857), according to Dr. Farr's "Life-table for Females," to 100,000 men living, of the age of 20 and under 21, there were 813 deaths annually; to 100,000 females living, 841 deaths annually, or 1 in 123 men and 1 in 119 women of that age die annually. And of men of the age of 20 and upwards, 1 in 39.99 dies annually; of women of the age of 20 and upwards, 1 in 40.65 dies annually; the mean after-lifetime of these are 39.99 years for men, and 40.65 years for women.

"At the present time, among all the people of England, including the poor as well as the favored classes,

the expectation of life at the age from birth to 20 is for males, over 45 (45.74) years, and for females, 46 (46.46) years; and at the age from 20 to 25, it is 38 years for males, and about 39 (38.98) years for females."*

The mean average duration of life from birth, in Philadelphia, for the 11 years ending December 31st, 1871, I have determined to be 24.99 years, or, still-births included, 23.60 years. †

In the city of Providence, R. I., the mean average age attained by decedents from 1856 to 1870 was 27.09 years. The average age attained by all the males who died in Rhode Island in 1871 was 32.57 years, and the average age of all the female decedents 34.43 years.

Tables of assignable annuities for lives, kept in Holland for 145 years, show that a given number of females lived about 3 or 4 years longer than the same number of males. ‡

INFLUENCE OF CITY AND COUNTRY LIFE.

One of the most curious facts in connection with the relative longevity of the sexes is the influence of country and city life. Women are longer-lived in cities than in the country, while men are longer-lived in the country than in the city, as may be seen by the following:—

Quetelet§ says that "the prosperity of the state ought to consist less in the multiplication than in the conservation of the individuals of which it is composed."

This authority finds the mortality in cities in Belgium, as compared with country districts, as 4 to 3.

After birth, according to Quetelet, the probabilities of life in Belgium are as follows:—

	MALES.	FEMALES.
In cities	21 years.	28 years.
In country	24 "	27 "
At 5 years in cities	48 "	51 "
At 5 years in country	51 "	48 "

The probability of life reaches its maximum at five years.
